HAYDN, Joseph, the most celebrated composer of music among the moderns, was the son of a wheel-wright, and born in 1732 at Rohrau in Austria, 36 miles from Vienna towards the Hungarian frontier. His father, though ignorant of the principles of music, which are much more generally disseminated among the lower ranks of Germany than in Britain, played a little on the harp, which was accompanied by the voices of himself and his wife. Joseph having been conducted, at a very early age, by a relation to Haimbourg, was instructed in the elementary parts of education; and a chapel-master of Vienna, having accidentally heard his voice, took him, when only eight years old, to replace one of the boys in his choir. Here he remained apparently exposed to severe discipline; and as his voice was constantly improving, the chapel-master became anxious to preserve it. He explained the means of doing so to Haydn, now a youth of about fifteen, who thought of nothing but music; and having gained his ready assent, the day and hour were fixed. But the accidental arrival of his father in Vienna, prevented their purpose from being effected. His voice soon broke, and Reuter, the chapel-master, ashamed of the reproaches which he had incurred, and exasperated at the disappointment, found a pretence for discharging him from the choir on a winter's night, which, from absolute poverty, he was obliged to pass in the street. Next morning, being observed by Spangler, a poor but friendly musician, he obtained a lodging from him in a hay-loft, adjacent to a single apartment which his own family occupied, and also a share of their frugal subsistence.

Here Haydn followed the bent of his early propensities, in practising on a wretched spinette; but it is said, that after some time had elapsed, a lady of rank, who had seen one of his compositions, desired to know the author. Haydn's extreme poverty hardly enabled him to obtain sufficient clothing to appear before her; and she had some difficulty in believing that he was the individual for whom she sought. He was compelled to account for his necessities, by relating, in as delicate terms as possible, his adventure with Reuter; and, in testimony of her esteem, she presented him with the works of Matheson, Bach, and other celebrated composers. According to some writers, his patroness was a niece of Metastasio the dramatic author, the real owner of the hay-loft; and they add, that he continued to instruct her in music and singing during three years.

Haydn now earned a scanty subsistence by the exercise of his talents. He was organist to an ecclesiastical establishment, with a salary of 12*l.* yearly. He had occasional employment elsewhere in the same capacity, and he sung, and played on the violin. At about the age of eighteen, he composed a quartett for Baron Furnberg, and afterwards some trios, which were surreptitiously printed. In the year

1759, his patroness obtained for him the appointment of music master to Count Marzin, with an annual salary of 25*l.*; and here he composed the first of those symphonies which have gained him so much celebrity. There appears to be some ambiguity respecting the chronology of Haydn's compositions. His *Opera Prima* consists of six quartetts, wherein all the rudiments of his fine genius are sufficiently developed; but it is reported, that the first time his name appears is to trios and harpsichord sonatas, in a German catalogue of 1763.

In the year 1760, Haydn was appointed sub-chapel master to a German potentate, the prince of Esterhazy, who was himself a siklful musician; and on the death of Werner, who was the principal, and from whose disposition and abilities he derived much advantage, he was promoted to fill his place. In this new situation, he had an ample opportunity, and sufficient encouragement, to pursue his talent for composition in its utmost latitude. Works of various descriptions flowed from his pen in rapid succession; and the particular taste of his patron led to the composition of those which no preceding musician had attempted. He overstepped all the limits which had fettered others; and, in adopting a new and peculiar, though unaffected style, he taught the public the variety of which music is susceptible. Yet this was not accomplished without exciting the jealousy of his cotemporaries. It has been affirmed, that he silenced his adversaries by publishing compositions wherein their own style was introduced, to betray its inferiority. In order to gratify the prince, he composed music with uncommon distributions of the parts or the performers; such as the *Echo*, which consists of a double trio for two violins and a violoncello, each set of performers being in a different chamber, but within their mutual view. Profiting by this singularity of taste, he composed another piece, called the *Adieu*, on occasion either of a quarrel in the orchestra, which induced all the band to give in their resignation, or, what is less probable, because the prince treated some of Haydn's warmest exertions with marked neglect. This was a symphony ingeniously devised, so that one instrument should regularly close after another; and as the music gradually terminated, each performer saw written before him, "Put out your candle, and go about your business." All obeyed in succession, and a solitary instrument finished the whole.

Haydn's time was principally occupied in musical composition; he generally dwelt with the prince of Esterhazy, at Eisenstadt in Hungary, and accompanied him during two or three months of the year, which were spent at Vienna. Here he became acquainted with the Chevalier Christopher Gluck, an eminent composer for the opera, Mozart, and others. The former advised him to travel in France and Italy, from which he predicted the greatest advantage in dramatic compositions; but the moderate finances of Haydn seem to have deterred him from following his counsel. His fame, however, had extended far beyond the sphere of his residence; and he was employed to compose an instrumental oratorio on the seven last sentences of our Saviour, for some religious ceremony, in a cathedral at Cadiz, which was hung with black, while a single lamp glimmered over the audience. Twelve years later, Haydn, without changing any of the instrumental parts, had words adapted to it. Many of his compositions are quite unknown in Britain, particularly a multitude of pieces for the bariton, a kind of small violoncello, with five strings above the bridge, and others behind the hand, to be touched by the thumb, played on by the Prince of Esterhazy, and to which the inhabitants of this country are strangers.

By the advice of Baron Van Swieten, Haydn visited London; and his residence there may be regarded as one of the most fortunate periods of his life. His great and steady patron the prince of Esterhazy had died in the same year, 1790; and while he left him his usual salary, he also dispensed with his discharging the duties of the situation. He seems indeed to have held him in great estimation; for when Haydn's house at Eisenstadt was burned down during his absence at Vienna, the prince directed another to be built, having exactly the same size, appearance, and accommodation.

In London Haydn experienced the most gratifying reception; he remained there eighteen months, and returned to the continent in the year 1794. He now began to be treated with those honourable distinctions due to his transcendant genius. He was created Doctor of music by the University of Oxford, and other literary and musical associations soon followed the example. At this time a concert on a liberal and expensive plan was established by Salomon, the late leader of the opera, where all the first performers were engaged; and each performance was announced to commence with an overture, expressly composed for it by Haydn. Twelve symphonies, which stand unrivalled, were thus produced; and, as is well known, these were afterwards ingeniously reduced to quintetts by Salomon. Some of them, or the whole, have since been adapted as trios for the piano-forte, violin, and violoncello. Haydn also composed and published several other works while in London; several of which are dedicated to the amateurs of this island: and a still more essential result was, the universal diffusion of a taste for his music.

During his absence from Germany, a tablet, or obelisk, had been erected in honour of him at Rohrau, the place of his nativity, by Count Harrach; and on returning to the continent, he composed the oratorio of the *Creation*, in 1795, which is esteemed among the finest and most elaborate of his works. But his other compositions of the same kind, the *Seasons*, *Stabat Mater*, *The Last Words of Christ*, and *The Return of Tobit*, have not been all equally successful; partly, it is supposed, from the want of coincidence between the music and the words. The last, however, which was written in 1775, is performed annually at Berlin, for the benefit of the widows of musicians.

While Haydn approached that period of life when the faculties usually decline, he was loaded with honours, and his vigorous invention continued to be unimpaired. He received honorary degrees from the academies of Stockholm and Amsterdam in 1798 and 1801; and in the following year, on a vacancy occurring in the National Institute of France, he was elected a member, at which time our countryman Mr Sheridan was one of the candidates. He was also chosen a member of the Phil-Harmonic Societies of Layback and St Petersburgh, and of the Children of Apollo at Paris, in 1805, 1807, 1808. Nay, the last struck a medal, bearing his portrait, and invited him to the capital, with an offer of a sufficient sum to defray his expences. But this was not all; for prince Kurakin, the Austrian ambassador at Vienna, presented him with a letter from the Phil-Harmonic Society of Petersburgh, full of gratitude and admiration of his works, and accompanied by a large gold medal, weighing above half a pound, struck in honour of him, and bearing his portrait, with the most flattering legend. He is also said to be the hero of a Spanish Poem on music.

But Haydn was now little more than sensible of the distinctions he received. He bent under the weight of years, and ceased entirely to compose about 1803. It was not without regret, however, that he witnessed his own decay. He feelingly deplores it in a vocal quartett, beginning, "My strength is enfeebled, death awaits at my gate." Indeed he was so much weakened, that it became necessary to construct a piano for him, remarkably light and easy in the touch. We have even heard those who knew him well declare, that he relapsed into a second childhood.

Haydn dwelt constantly at Vienna, and confined himself to his house and garden after the year 1806. The seventy-third anniversary of his birth had been celebrated by a concert in one of the theatres, conducted by the son of Mozart; and, in 1808, a great musical association of that city resolved to close the performances of the season with the *Creation.* Haydn, though withdrawn from the world, consented to be present. He was received by the Princess Esterhazy, and others of distinguished rank, in the hall of performance, and carried, amidst the sound of trumpets and loud acclamations, to a particular part of the gallery which was appropriated for him. He was overwhelmed by this mark of approbation; and upon retiring, which he did very early, signified that he felt it was for ever. This great composer expired on the 31st of May 1808.

Haydn's personal appearance betrayed no indications of genius. His stature was large, and his features coarse. But he was mild and complacent in manners; modest and unassuming; and universally beloved in private life. He was never tainted by jealousy, and, unlike those who proclaim their own merits by undervaluing the works of others, he was always ready to approve where approbation was due. Handel's chorusses he thought sublime, though his music might be defective in melody. He entertained the highest opinion of Mozart, declaring his death a public calamity: and when invited to be present along with him at the coronation of the Emperor Leopold at Prague, he observed, "Where Mozart is present, Haydn ought not to appear." Haydn indeed was too reserved. That innate modesty, and his moderate finances perhaps, prevented him from attaining some distinguished situation in his own country, which his talents merited. The Emperor Joseph is justly reproached with neglecting to place the first musician at the head of his orchestra; but probably it is there, as it is in many other countries, that men of real genius are superseded by those who have none. He enjoyed a competency in his later years, but his total fortune did not exceed 250*l.* at the period of his first visit to Britain. He was married many years, but not happily: and he had long been separated from his wife. Two brothers, Michael and John, survived him. The former, who had considerable merit as a composer, died master of the band to the court of Salzbourg; the latter died in the service of the Prince of Esterhazy.

Haydn's compositions exist in the most astonishing variety. They are calculated to amount to 842, including those of every description: and the following is said to be an abstract of a catalogue furnished by himself in the year 1805. Symphonies, 118; various pieces for the baritons, 163; instrumental pieces of from five to nine parts, 20; marches, 3; trios for two violins and a bass, 21, and 3 for two flutes and a violoncello; 6 solos for violin with tenor accompaniments; 3 concertos for violin and violoncello: 1 for the double bass; 2 for horns; 2 for the trumpet; 1 for the flute; 1 for the organ; and 3 for the harpsichord; 66 sonatas for the piano forte, and 83 quartetts. Another unfinished quartett was found at his death, to which some portion that was wanting has been supplied; and it was performed at a grand concert in commemoration of him at Berlin in October 1809. This assembly was opened by an eloquent eulogium on his merits. He also produced 34 compositions of church-music; 5 oratorios; 19 or 20 operas; 13 airs in 3 or 4 parts; 42 simple songs and duetts; 40 canons. Besides these, he wrote preludes and basses for 365 Scotch airs; and composed above 400 minuets, dances, and waltzes. At his death there were found 46 unpublished canons, framed to ornament his apartment; not being rich enough, he said, to purchase pictures, he had himself made tapestry to cover the walls.

Amidst such an infinity of works, the whole of which have probably never been heard by any one individual, it is difficult to determine where the preference is due. But the fertility of imagination is conspicuous throughout, and Haydn's compositions are ever new. Perhaps he has been less successful in the vocal than the instrumental departments. None has ever equalled his distribution of music in the orchestra, or called forth the single and combined powers of instruments in an equal degree. Here he has excelled all his predecessors, his cotemporaries, and successors; and those pieces which he has written for a full band stand unrivalled, whether we attend to the unity of design, the relation of parts, or that sudden burst of grandeur which amazes the auditor. Next to the symphonies, Haydn's quartetts seem to be most admired; they are written with apparent simplicity, but almost all of them present considerable embarrassment, unless to skilful performers. This composer is one of the few who presents perpetual novelty, who never imitates himself, and who adapts intimately and exactly the music to those instruments for which it is designed. None of his music is tedious or languid, unlike some modern compositions, whose authors, ignorant that they are producing nothing more than preludes or voluntaries, suppose they have taken up an inexhaustible theme. His minuets and trios are perhaps devised with more ingenuity, and more calculated to please than any that have appeared, and he is particularly successful in variations on an air, and in modulations. Yet it is vain to affirm that equality pervades his works; and it will not appear surprising if inferiority be sometimes discovered in such a multitude. We should remark, as a very extraordinary fact, that the lapse of years had no effect in diminishing the quality of his compositions. The first quartett of the first opera, and his last which he wrote, are excellent, though there be some difference in their style. Hadyn ventured far and was successful; many have endeavoured to follow the same course with doubtful approbation. Perhaps had Mozart not been prematurely cut off, he might have approached to him in excellence; but as yet Haydn is entitled to be designed the first of modern masters. (*c*)

HEADLEY, the Rev. Henry, an English poet and critic, whose highly promising talents were unfortunately lost to the world at the early age of 23, was the son of a clergyman in Norfolk, and was born at Irstead in that county in 1766. He was educated at the grammar school of Norwich under Dr Parr, and was admitted a commoner, and elected a scholar of Trinity College, Oxford. At the university, the living example of Thomas Warton, then the Senior Fellow of Trinity College, seems to have communicated to Headley an enthusiasm for the elder school of English poetry. While combining this pursuit with his classical studies, he published his poems and other pieces in the year 1786; and in the following year, at the age of 22, he published Select Beauties of Ancient English Poets, with Remarks. In his poems, though marked by elegance and sensibility, there was no promise of transcendent genius; but his Remarks on the Elder Poets displayed an extent of reading, a comprehensiveness of views, and a perspicuity of taste, which were justly regarded with wonder in so young a writer. He cannot, indeed, be said to be wholly free from partiality and exaggeration, in estimating the elder writers, whose beauties he complains of being neglected; but still, as a critic, he deserves to be remembered in English literature. Mrs Cooper, in her neat Biographies and Selections, led the way in preserving the memory of our early poets; Warton contributed immense industry in illustrating our literary history; Percy restored to us our ballad poetry; but in the selections and criticisms of Headley, there is a classical taste and condensation of materials, more elegant than what we meet with in any of his fellow labourers in the same pursuit. His critiques are like the portraits of a master, flattered indeed, but done with general truth and animation. His life was too short to have many events. Some months after leaving Oxford, he married, and retired to Matlock in Derbyshire, in a spot where the wild scenery accorded with his romantic turn of mind. But the symptoms of a consumptive tendency, which had before appeared in his delicate frame and constitution, began now to make rapid advances; and being warned to try the benefit of a warmer climate, he had the resolution to take a voyage to Lisbon, unaccompanied by any one he knew. On landing at Lisbon, far from feeling any relief from the climate, he found himself oppressed by its heat. A few days would have probably terminated his life, when a Mr De Visme, to whom he had received a letter of introduction from the late Mr Windham, invited him to his healthful villa, near Cintra, allotted spacious apartments for his use, procured for him an able physician, amused him with his elegant books, and gave him every chance of benefiting from the change of climate. But his malady was incurable; and having returned to Norwich in the month of August, he expired there, in Nov. 1788, in the 23d year of his age. (*z*)

# HEAT.

Heat is a term which was originally employed to express the effects produced by a peculiar condition of bodies, when they communicated the sensation of warmth. It was also perceived that hot bodies, or those that had the power of communicating warmth, possessed other properties, such as that of expanding the substances to which the warmth was imparted, of converting certain solids into liquids, and certain liquids into the state of vapour, and many other operations of great importance in the system of nature. Philosophers soon began to speculate upon the cause of these phenomena, and, with a degree of inaccuracy, to which we are liable in the infancy of our scientific pursuits, they employed the same word to signify both the *cause*, and the *effect* produced. It was commonly said, that *heat* occasioned the warmth and expansion of bodies, and likewise that *heat* was excited in bodies by the addition of some peculiar kind of matter, or by a certain modification of their particles. The more precise nomenclature of the moderns has tended to correct this error, and has led to the invention of a new term, *caloric*, to designate the *cause*, while the word *heat* is, strictly speaking, only applicable to the *effect*. As, however, in all the older authors the former phraseology necessarily exists, as it is still adopted in popular language, and as there is no danger of falling into any error, since the distinction has been so fully pointed out, the word *heat* is frequently employed in its double sense, even by the latest and most correct writers, and it will be used in this way in the following article.

We have already given some account of the nature and effects of caloric under the head of Chemistry; but it is an agent of such extensive importance in the operations of nature,—it produces such powerful effects both upon organized and unorganized matter,—it is so intimately connected with the existence of life, both animal and vegetable,—and is so essential to all the processes by which we act upon the bodies around us, when we convert them to our support or utility,—that it well deserves to be farther discussed, and made the subject of a separate article. The importance of the object has produced a consequent share of attention to it from the modern experimentalists; and there is perhaps no one topic on which more curious, and, we may add, more unexpected results have been obtained, than have ensued from the researches into caloric. The names of Black, Crawford, Rumford, Pictet, Gay-Lussac, Prevost, Dalton, and Leslie, among many others which will be afterwards referred to, must suggest the recollection of the many ingenious and elaborate trains of experiments, that have occupied the attention of philosophers during the last 50 years. It will be to an account of what has been done in this period that we shall principally confine ourselves in the following pages; for the experiments and hypotheses that were published before this time, are rather to be regarded as curious historical records of opinions, than as affording much that is important in the actual advancement of knowledge.

We shall arrange our observations on heat under four heads: 1*st*, The properties of heat; 2*d*, The effects of heat; 3*d*, The sources of heat; and, 4*th*, The nature of heat. In the course of the article, we shall take an opportunity of tracing the gradual developement of the leading opinions that have successively prevailed on these topics, as well as the most important experiments by which they have been supported.

## SECT. I.

### *On the Properties of Heat.*

It might, at first view, appear more regular to begin by investigating the nature of heat, before we described its properties and effects; but it is so difficult to ascertain its nature, and the knowledge which we possess, or rather the conjectures which we form concerning it, are so entirely derived from the observations that we are able to make of its properties and effects, that the order of treating the subject which we have adopted, will be found, we apprehend, the most convenient. For the present, we may consider heat, or caloric, to be a principle or power existing in bodies, which gives rise to many of their most important actions, and modifies their effects upon other substances.

The *properties* of caloric are of three kinds: Those that are strictly mechanical, or such as may be conceived analogous to the laws of gravitation or impulse; chemical, or those that tend directly to effect a chemical change in bodies; and a third class, which may be regarded as specific, and which do not bear an exact resemblance to either of the two former.

Among the mechanical properties of caloric are its radiation, reflexion, and refraction, which bear a very near resemblance to the same affections of light. Some obscure intimation of the radiation of heat may be met with in the authors of the latter part of the 17th and beginning of the 18th centuries, but the subject was not much attended to until the time of Scheele. This distinguished philosopher, in his investigation of the nature of fire, performed some new and decisive experiments, which completely established the existence of this property, and shewed how it differed from the power which hot bodies possess of communicating warmth by contact. He found, that when glass is interposed between the face and a quantity of burning fuel, although the light passes through without interruption, the heat, at least for a certain space of time, is entirely stopped. Heat, he observed, radiates through air, without communicating any warmth to it, and its passage does not appear to be interrupted by any currents in the atmosphere. He found, that a transparent mirror, which concentrates the rays of light, does not produce any increase of temperature in the focus until it has absorbed a sufficient portion of heat, but it then becomes a radiating body, and emits heat in certain directions. The conclusion which may be deduced from Scheele's experiments is, that caloric is sent off in rays from all hot bodies, and moves through the air with great velocity, but that in this transmission it does not necessarily communicate warmth to it, and is not diverted from the straight course by any currents or motion of the air itself: (*On Fire*, p. 70, *et seq.*) His experiments also tended considerably to elucidate another point respecting heat, which had been the subject of much controversy, whether it was not identical with light, or only differing from it in consequence of some slight modification of its properties. Heat and light are so frequently observed in connection with each other, emanating from the same sources, and produced, as it would appear, by the same agents, that the opinion of their identity was generally adopted, at the commencement of the last century. Some distinguished experimentalists had indeed embraced the contrary doctrine, and some facts were brought forward in its support. Instances perpetually occurred, of high degrees of heat being produced, which were not accompanied by light; and, on the other hand, it was found, that there were some luminous bodies which were not hot, and especially, that the moon's rays might be concentrated by a lens, or mirror, so as to produce a very brilliant light, yet that no sensation of heat was excited. These, however, and some other analogous facts, were not deemed sufficiently conclusive to establish the point. Some authors regarded heat and light as the same substance in different states; while those, who did not admit their materiality, conceived that they depended upon the same affection of matter, but differing in its degree or intensity. Scheele's experiments seemed to prove, that heat and light, when closely united together, as in the rays of the sun, or of a burning body, may be completely separated, so that the specific effects of each may be obtained distinct from the other. We have already referred to his observation of the manner in which a sheet of glass permits the light to pass through it, while it intercepts the transmission of the heat; and he also found, that if rays composed both of heat and light, as they were sent off in combustion, be received upon a glass mirror, the heat is absorbed, while the light alone is reflected.

The distinct nature of light and heat is rendered still more probable, by some late experiments of Dr Herschel's, in which he separated them from the state of combination in which they exist in the sun's rays. He was led to observe that the differently coloured rays possess different powers of producing heat; the least refrangible rays, those which excite the sensation of red, possess the greatest heating power; and the power diminishes, until we arrive at the violet, or most refrangible rays, which excite the least heat, the intermediate colours possessing an intermediate power in this respect. But he not only discovered that the rays of heat and of light were thus very differently affected by the prism; he farther found, that the effect upon the thermometer was most considerable in a point beyond the red-making rays, entirely out of the limits of the spectrum, and, of course, in a spot on which no part of the luminous ray was received. Beyond this point, where the temperature was at its maximum, the heat gradually diminished, until it was no longer perceptible: (*Phil. Trans*, 1806, p. 286. *et seq.*) From these experiments, the results of which were verified by Sir H. Englefield, who employed an apparatus of rather a different kind, we learn, not only that heat is emitted in rays from the sun, but that solar heat may be obtained separate from light; and although, like light, it is possessed of the power of being refracted, yet it possesses this power in a different degree. In Sir H. Englefield's experiments, where the blue rays raised the thermometer to 56°, the green to 58°, the yellow to 62°, and the red to 72°, the space beyond the prismatic spectrum elevated it to 79°, and it sunk to 72°, when returned into the red rays: (*Journ. of Royal Inst.* i. p. 203.) Similar results were obtained by M. Berard; but he observed, that the maximum of heat was at the very extremity of the red rays, when the bulb of the thermometer was completely covered with them; and that beyond the red extremity, where Herschel found the heat to be a maximum, it was only 1-5th above that of the ambient air. See APPENDIX to this article.

The radiation of heat was exhibited in a still more decisive manner by Pictet, who seems to have undertaken his experiments on the subject at the suggestion of Saussure. This distinguished naturalist was led to form some speculations concerning caloric, from certain atmospherical phenomena, which he noticed during his travels among the Alps, where he conceived that the communication of heat could not be accomplished by the contact of the heated body. He refers to an experiment of Mariotte's, which was published in the Memoirs of the Academy of Sciences for the year 1682, in which he states, that "the warmth of a fire reflected by a burning mirror is sensible at its focus." Lambert also informs us, in his *Pyrometrie*, that he placed a burning body in the focus of a concave mirror, and that he was able by means of it to inflame another body, placed in the focus of an opposite mirror, at the distance of above 20 feet. In this experiment, Lambert distinctly marks the difference between what he calls "luminous heat" and "obscure heat," and attributes the effect to the latter principle, *i. e.* to heat, properly so called, in opposition to light.

Saussure repeated the experiment in conjunction with Pictet; and, in order to prevent the interference of the action of light, they employed a ball of iron, heated to a degree short of what would render it luminous in the dark. They used tin mirrors, that were placed more than 12 feet from each other: and, when the iron ball was put into one focus, they suspended a thermometer in the other, and observed the instrument to be very perceptibly affected, more than another thermometer, equally near the ball, but out of the focus. The former was raised from 4° to 14½° of Reaumur; the latter from 4° to 6½° only: (*Voyages dans les Alpes*, § 926.) The result of this experiment is easily explicable, upon the supposition that heat, whatever be its nature, radiates in straight lines; that it impinges against solids that are opposed to its course; and that, according to circumstances, it either raises the temperature of this body, by being united to it, or is reflected from its surface. The heated ball, in this case, emitted rays of heat in every direction: those that were contiguous to the mirror fell upon it; but, owing to its polished surface, were reflected in straight lines to the other mirror, and were again reflected from this, according to the laws of mechanical impulse, into the focus in which the thermometer was suspended. This thermometer received the effect both of the rays that were sent off by the iron ball, on the side contiguous to it, and of those which were on the contrary side of the ball, next to the mirror; whereas the thermometer not in the focus, only received heat from the side of the ball opposed to it. Pictet's apparatus is shewn in Plate CCLXXXVIII. Fig. 9. See Description of Plates.

M. Pictet still further prosecuted these experiments, and varied them in different ways, so as to repel the objections that might be urged against the conclusions which he derived from them. In order to separate the light from the heat, and to shew the distinct operations of each, he placed a lighted candle in one of the foci, and noticed its effects upon a thermometer placed in the other focus. He then interposed a plate of glass between the candle and the thermometer; and he found, as he had expected, that although the light passed as before, a considerable portion of the heat was intercepted in its passage from one mirror to the other; in this way confirming the results that had been formerly obtained by Scheele. But, in order to remove more effectually all suspicion that the effect in this case depended upon the rays of light, he placed a small flask of boiling water in the focus, from which we may be confident that no light could be emitted: and this he found to radiate heat, and to raise the thermometer very perceptibly. The experiments of Pictet may therefore be considered as completely establishing the point, that heat is sent off in right lines from bodies, where light cannot be supposed to be present. He also rendered the radiating power of caloric still more obvious, by shewing, that when rays of heat impinge against a body, if it have a polished surface, they are reflected from it; but, if the surface be such as not to admit of reflection, they enter into it, and raise its temperature. In pursuance of this idea, he found, that when the bulb of the thermometer which he employed was blackened, it rose more rapidly, or absorbed more heat, than when its surface was clean and bright, thus proving, that the heat from boiling water was, in this respect, similar to the heat in the sun's rays, or that emitted during combustion: (*Essay on Fire*, § 51, *et seq.*) We have already referred to the experiments of Dr Herschel, in which he analysed the sun's rays, and separated the part which produces heat, from that which excites the sensation of colour. These experiments proved, in a very decisive manner, the radiating power of the calorific part of the solar beam; and he afterwards made experiments of a similar kind, upon different species of heat, extricated from bodies on the surface of the earth, such as burning fuel and red hot iron. *Phil. Trans.* 1800, p. 316.

An interesting train of experiments, on the manner in which heat radiates, or escapes from the surfaces of bodies, was performed by Rumford, in which he shewed, with his usual address and dexterity, the different effects which are produced by a difference in the nature of the radiating surface: (*Phil. Trans.* 1804, p. 89 *et seq*) By a singular coincidence, nearly about the same time that this essay was published in the *Phil. Trans.* a still more complete view of the subject was taken by Professor Leslie. They both supported their peculiar opinions by a number of well contrived and well executed experiments, which led to many curious and unexpected results, and which have, in some measure, altered our previous notions respecting the nature of heat, or at least respecting some of its most remarkable properties. It had been before known, that the nature of the surface of a body materially affects its power of admitting caloric to enter into it; and this power was now extended to the emission or radiation of heat.

There is so much similarity between the experiments of Rumford and Leslie, that it will not be necessary to refer to both of them, considering the narrow limits to which we are confined in this article; and as those of the latter are generally the most decisive, and, for the most part, performed with the most accurate instruments, we shall principally employ them in our examination of the subject.

Professor Leslie's researches illustrate, in a striking manner, the effect of the peculiar nature of the surfaces of bodies, both upon the emission and reception of radiant heat, bodies of equal temperatures discharging and absorbing it in very different degrees. When a body sends off rays of heat, we may conceive that it parts with a portion of caloric that was previously united to it; and that when it receives the rays of heat, a quantity of caloric becomes combined with it, which was before in a free state. These two operations, although the reverse of each other, seem to exist in the same proportion, and in all respects to bear an exact ratio to each other. Professor Leslie employed in his experiments a species of air thermometer of a new construction, which, besides possessing the advantage of being an instrument of great delicacy, and being sensible to very minute variations of heat, has also the useful property of indicating, at all times, any variation that occurs in the temperature of the portion of air in which it is immersed, and of adapting, as it were, its own scale to this new temperature, so that the apparent effect is the same, whatever be the actual temperature at which the experiment is performed. It was from this property that he gave to his instrument the name of *differential thermometer*, as not indicating the actual degree of heat, but only the degree in which it differs from that of the atmosphere. (It is shewn in Plate CXLI. Fig. 1.) Rumford employed an instrument very similar in its nature, which he called a *thermoscope*.

In ascertaining the quantity of heat emitted from the surfaces of bodies, Professor Leslie generally examined the rays after they had been reflected by concave mirrors. Those which he used were composed of polished block tin; and by means of a mould, upon which they were formed, they were made to constitute portions of the parabolic curve. The substance from which the heat was emitted was boiling water, contained in a cubical canister of block tin. This was provided with a thermometer to ascertain its temperature; and the apparatus being placed in the focus of an elliptical tin reflector, the effect was noticed upon the differential thermometer, situated in the opposite focus. The canister had four sides of equal dimensions; and these being prepared in different ways, either polished, or left rough, varnished, or covered with paper, or some other substance, afforded an opportunity of accurately examining and comparing the effect of different kinds of surfaces on the radiation of heat: (*Inquiry*, p. 17.) The apparatus is shewn in Plate CCLXXXIX. Fig. 11. Professor Leslie begins by ascertaining what was the effect of the canister of boiling water, when simply placed in the focus of the reflector, in what length of time the maximum of heat was produced, and how long the process of cooling occupied. He likewise observed the effect produced on the thermometer, by employing water of different temperatures, and also by the degree in which the temperature of the water exceeds that of the temperature of the air of the chamber in which the apparatus is situated. The vessel that contained the water was a cube of six inches; and when it was at the boiling heat, and was placed at the distance of about three feet from the mirror, the rise of the differential thermometer was equivalent to what would have been 14.5° of Fahrenheit's scale. He also found that the greater was the excess of the heat of the water above the temperature of the room, exactly in the same proportion was its action on the thermometer. Hitherto the vessel had been employed with its uncovered side turned towards the reflector; and he next proceeded to contrast with this the effect of the other three sides of the canister, one of which had a plate of glass cemented to it, another had writing paper pasted on it, and the fourth was covered with a varnish of lamp black. The effect produced by these different surfaces was very singular, and was, to the experimentalist himself, very unexpected. The uncovered side, which had the usual polish of a metallic surface, produced an effect upon the thermometer equal to 12°, the side to which the glass had been applied to 90°, that covered with paper to 98°, while the varnished side was equal to 100°. From these experiments we arrive at the important conclusion, that heat radiates from a polished metallic surface with not quite $\frac{1}{8}$th part of the energy that it does from a surface that is covered with some substance, which takes away the effect of the polish. *Inquiry*, p. 18.

An experiment, which may be regarded as the reverse of the above, was afterwards tried. Here the thermometer was made to receive heat from the canister, its bulb being first left in its usual state, and afterwards covered with tin-foil carefully applied, so as to admit of a degree of polish. It was then found, that the coated thermometer, analagous to the polished side of the canister, received only about $\frac{1}{5}$th as much heat as when the instrument was without the metallic covering. The power of surfaces in absorbing heat, seems therefore to be intimately connected with that of radiating it, materially influenced by the nature of the surface, much less, when consisting of polished metal, and greatly augmented when covered with paper, varnish, or any other not-metallic substance. These experiments seemed to indicate, that the power of radiating and of absorbing heat was in an inverse ratio to that by which heat is reflected from surfaces; and this point was afterwards made the subject of direct experiment by Professor Leslie. He had already found, that the polished surface of the canister was a bad radiator, and that the coated thermometer, in consequence of its polish, was equally unfitted for absorbing heat. The next object was to examine, whether these surfaces, which were the least fitted to radiate and absorb it, were not as much superior in their reflecting, as they were defective in their radiating, power. The tin reflector was removed, and in its place was substituted one of glass, while the canister of boiling water, and the differential thermometer, were placed as before in the respective foci. In order to produce the greatest action upon the mirror, the varnished side of the vessel was opposed to it; but the effect produced by reflection in this case was not considerable. No important alteration was produced, by removing the metallic coating from the back part of the mirror, or by roughening it with emery; but when the anterior surface of the glass was covered with Indian ink, no heat was sent off from it. On the contrary, when the front of the mirror was coated with tin-foil, the thermometer rose ten times as much as it did from the effect of the naked glass. These experiments, when compared with each other, lead to the following conclusions: That when the rays of heat strike against polished glass, a large portion of them is absorbed, and tends to raise the temperature of the glass itself; but when they impinge against polished metal, few of them enter the metal, and nearly the whole are reflected. *Inquiry*, p. 21.

Professor Leslie having now fully established the connection between the radiating and the absorbing power of different kinds of surfaces, afterwards proceeded to vary the effects in different ways, and to compare them with each other under different modifications. We have mentioned above, that the polished side of the canister, when opposed to the mirror, produced in the differential thermometer a certain rise, which we have called equal to 12, that of the varnished surface being estimated, as a standard of comparison, at 100. When the tin was rubbed with a small quantity of mercury, an effect was produced equal to 14, and when completely coated with it equal to 20. As the brilliancy in this case appears not to have been less than from the pure tin, we must conclude that there is either a different radiating power attached to different metals, independently of their mechanical properties, or that an amalgam of tin and mercury was formed of a soft consistence. It was afterwards found, that when a metal loses its brilliancy by oxidation, the radiating power is increased in the same proportion: a fresh surface of lead raised the thermometer only $\frac{1}{4}$th as much as the lead when covered with a layer of minium. This effect of oxidation might perhaps have been predicted from the preceding experiments; but the alteration caused by simply scratching or roughening the metal, seems more remarkable. If the perfectly smooth surface produced on the thermometer an effect equal to 12, by rubbing it with a file or with sand, so as quite to destroy its polish, an elevation took place equal to 26, or rather more than twice as much as the former. It was afterwards found, that when the tin canister was coated with an animal substance, such as jelly, if it was spread upon it only to the thickness of a fine film, it raised the thermometer to 38; but when laid on so as to form a thick coating, the effect was about twice as great, or near 80. The effect in this case, was not found, however, to bear an exact ratio to the thickness of the coating; nor was a difference in the thickness of the coating observed to have any effect, except when an animal substance was used, or something of a similar nature, for metallic coatings seemed to act merely from their surface. Some experiments were made upon the effect of colour, in modifying the radiating power of surfaces; but the results are not sufficiently uniform to prove any thing very decisive on this point. Although the most considerable effects were produced by lamp-black, yet, as has been mentioned above, writing paper was found to be nearly as powerful. We have already had occasion, more than once, to refer to the relation which exists between the radiating and the reflecting power of bodies, a fact which, although contrary to what might have been expected upon a transient view of the subject, is yet established by numerous and decisive experiments. Thus scratching the surface of the mirror, diminishes its reflecting power as remarkably as it augments its radiation; and also a layer of animal matter spread over the face of the canister, diminished its reflecting power to about 1-3d, as was determined by the thermometer. *Inquiry*, p. 76. *et seq.*

Professor Leslie was afterwards led to confirm, and very much extend the views which Scheele originally suggested respecting the power of certain substances to retain the caloric which falls upon them by radiation, when they are such as not to send it off again by reflection. In this case, the body receiving the heat, experiences an elevation of temperature, until after some time it becomes itself a source or centre of heat, which emits it to other bodies. It was in this way that heat was separated from light, as we have already related, the light passing without interruption through a plate of glass, by which the transmission of heat is, for a certain time at least, entirely obstructed. When the heat is emitted or radiates from its new source, its progress is then found to be varied from that which it originally possessed, and to be entirely directed by the condition of the surface from which it last escapes. This property of heat was illustrated by a series of experiments, in which screens of different kinds were interposed between the mirror and the canister, to which we have so often referred: (*Inquiry*, p. 26, and 17.) A sheet of tin was found entirely to intercept the heat, and a plate of glass a considerable portion of it; but what constitutes a curious difference between the effect of heat and light is, that the quantity of heat intercepted varies greatly, according to the vicinity of the glass to the radiating body; more heat being transmitted when the glass is near the canister, than when it is more distant from it. But, perhaps, some of the most curious of all Professor Leslie's experiments were those in which he employed two screens of tin, one side of each of which was covered with the black varnish, the other being left uncovered. When these tin plates were laid together, with both their painted sides in contact, and of course the bright sides both external, little heat passed through them, because the side nearest the canister was not adapted to receive caloric, nor the other to radiate the little which might have been received; but when the varnished sides were placed externally, the quantity of heat that passed through them was considerable, because here the varnish enabled the one plate to absorb, and the other to radiate caloric with facility. When only one plate was used, intermediate effects were produced. Several circumstances that were noticed by Professor Leslie, led him to conclude that the rays of heat, like those of light, where they proceed from a near object, are sent off in lines that have a sensible divergence. The radiation of heat seemed to be entirely suspended, by having the heated body immersed in water; and it appears probable that it cannot exist in any medium except air. *Inquiry*, p. 92.

We have already alluded to the experiments of Count Rumford, which were published almost immediately after those of Professor Leslie, and which so generally agree with them, that although they are both numerous and ingenious, it will not be necessary to give any minute description of them. Like Professor Leslie, Count Rumford found, that polished metal radiates heat in a much less degree than a metallic surface, at the same temperature, but covered with paint or varnish; that a covering of linen, flannel, paper, or in short of any animal or vegetable substance, tends to promote the emission of heat; and he farther found, that the radiation and absorption of heat bore a direct ratio to each other, and likewise an inverse ratio to the power of reflection. In one particular, indeed, the Count's experiments had a different result from Professor Leslie's; this latter experimentalist compared the radiating effect of various metals, and conceived that they differed from each other in this respect, while Rumford could not perceive any difference between them; upon the whole, however, we are disposed to regard Professor Leslie's results as the most correct. Count Rumford, according to his usual custom, deduces some important practical conclusions from his experiments, which are the more valuable, because some of them are precisely contrary to the previous ideas that were entertained upon the subject. In putting heated bodies into vessels or tubes, our object is sometimes to retain the heat as long as possible: but in others, on the contrary, we are desirous that the heat should be quickly dispersed through the contiguous air. If we wish to confine the heat, we must employ metal, and have its surface highly polished, a fact fully proved by the above experiments, but directly contrary to the conclusion that might seem to follow from the superior conducting power of a metallic body. On the other hand, if the object be to cool the vessels with their contents, or to transfer their heat to the surrounding medium, we must cover them with paint or varnish, or with some kind of soft coating, not of a metallic nature. As an example of the two cases, we shall mention that of tubes conveying steam, which may, in the one instance, be for the purpose of transporting heat from one vessel to another, and where, of course, it is an object that none should be lost in the passage; here we must use bright metallic tubes, which will radiate as little as possible. But if, on the contrary, we introduce steam tubes for the purpose of warming an apartment, here we wish to promote the radiation as much as possible, and we should therefore use the tubes unpolished, and varnished, painted, or even rusted. In the same way bright metallic vessels should be employed, when we wish to preserve the heat in fluids, where they are used for the purposes of cooking or manufactures, while the opposite plan is to be followed, when the object is to promote their cooling. (*Phil. Trans.* 1804, p. 177, *et seq.*) On the cooling of bodies we shall have occasion to speak more at large, in a subsequent part of the article.

We must now advert to a train of phenomena, connected with the radiating power of bodies, although perhaps depending upon a different principle, and leading to some new ideas respecting the nature of heat, the radiation of cold. By the radiation of cold we mean simply to express the fact, that when a cold body is placed in the focus of a concave mirror, a thermometer will fall that is suspended in the focus of an opposite mirror. This singular circumstance was first noticed by the members of the Florentine Academy, and was very distinctly described by them, although they were so much surprised at the effect, as almost to doubt the accuracy of their own experiment. (*Saggi di nat. Esper.* p. 176.) They do not seem to have made any atttempt to explain it; no farther notice was taken of it at the time, and it appears to have been almost forgotten, when Pictet, in the course of his experiments, to which we have referred above, after having ascertained the radiation of heat and its reflection by his apparatus, placed a vessel filled with ice in one of the foci, and observed the thermometer in the other focus instantly to sink several degrees; when the ice was removed, the thermometer rose again to its former elevation. By adding nitric acid to the snow, and thus producing a more intense cold, he found that the effect on the thermometer was augmented. *Essay on Fire*, § 69. See our article COLD.

The apparent radiation of cold has been since confirmed by Professor Leslie, and what may, at first view, appear still more remarkable, it seems to be acted upon by bodies in the same manner with radiant heat. It is promoted and retarded by the same kind of surfaces which promote and retard the radiation of caloric, and also in the same proportion. The canister, which had been employed in the former experiments, was now filled with ice or snow, and its different sides in turn exposed to the mirror, the differential thermometer being, as before, suspended in the opposite focus. The cold produced by the varnished side was the greatest, while that from the uncovered side was the least, the glass and the paper being intermediate between the two, exactly in the same manner as when the vessel had been filled with boiling water. The results also were similar when the thermometer was covered with different substances, so as to affect its power of absorbing heat, and also when the surface of the mirror was changed, so as to change its power of producing reflection. For example, when the thermometer was coated with a leaf of metal, it fell less, and when coated with varnish, more than in its ordinary state. And with respect to the mirror, the reflection of cold was most considerable from the bright metallic surface, less when a mirror of glass was employed, and still less when it was varnished. Here the power of the mirror in radiating cold, was exactly in the inverse ratio of its reflecting power, just as is the case with the radiation of heat. Lastly, the interposition of screens of different kinds, and with different surfaces, between the ice and the mirror, had effects which were precisely analogous to those mentioned above; so that under all circumstances, Professor Leslie found the strictest coincidence between the two kinds of radiation: (*Inquiry*, p. 23.) It may be proper to mention, that experiments of a similar nature, and with similar results, were performed on the radiation of cold by Count Rumford. They are such as sufficiently establish the facts, and might be esteemed valuable, were they not, for the most part, superseded by those of Professor Leslie. *Phil. Trans.* 1804, p. 170.

The general conclusions that may be deduced from the experiments of Pictet, Rumford, and Leslie, are, that bodies possess a power which generates cold, or reduces actual temperature; and that this power is emitted in right lines, and may be reflected, condensed, or intercepted, in its passage from one body to another, like the rays of radiant heat. It also follows the same laws with respect to the action of surfaces upon it, and bears the same relation to their reflecting property. Certainly the most obvious inference would be, that cold, like heat, depends upon the presence of a real material agent, capable of being transferred from one body to another, and subject to similar laws of radiation and reflection; but this supposition is so strongly opposed by many other considerations, which seem to prove, in the most decisive manner, that cold is merely a negative property, and signifies nothing more than the abstraction of heat, that we are compelled to look out for the explanation of the phenomena upon other principles: these we shall afterwards endeavour to elucidate.

We have very few remarks to make respecting the two other mechanical properties of heat, its reflexibility and its refrangibility. The reflection of heat has been abundantly proved by the numerous facts that we have stated, in which the concave mirrors were employed, as well as in all those where the nature of the surface absorbing the rays of heat affected this property; for it has been shewn, that in as much as the surfaces were unfavourable for absorption, they were, in the same proportion, favourable for the reflection of heat. The refraction of heat, as distinct from light, was clearly exhibited in Herschel's experiments; by its passage through the prism, it was diverted from its straight course like light, only in a greater degree, as the calorific rays are found to be dispersed over a larger space than the spectrum formed by the visible rays. The rays proceeding from a candle, or from burning fuel, were also found to be capable of refraction, like those of solar heat. We may conclude that the solar heat consists of rays of different degrees of refrangibility, although no other difference has been detected in their nature, as is the case with the differently coloured rays of light. This conclusion follows from the fact, that the space occupied by the rays after they have passed through the prism is greater than before they entered it. See Appendix to this article.

Before we conclude our account of what we have styled the mechanical properties of heat, we shall offer a very few remarks upon the velocity with which it moves. That the velocity must be very great, is a point of which there can be no reasonable doubt; yet it will be found very difficult to assign the actual velocity. It is perhaps the most probable conjecture, that heat, when radiating from a body, moves at the same rate with light; yet we know of no decisive arguments from which this can be inferred, as more than a conjecture. Pictet made some experiments upon this subject; but they only prove that no perceptible interval elapses in the passage of heat through about 70 feet, a space much too small to prove any thing important.

The second class of properties, which we announced as belonging to heat, are its chemical properties, or those that tend directly to produce a chemical change in bodies. We shall, however, postpone the consideration of these to a future part of the article, because we shall then be better prepared to determine, what properties ought to be regarded as chemical, after we have made ourselves aquainted with the effects of heat, as well as with the other properties that have not yet been considered, which we have styled *specific*. These we shall now proceed to examine.

The specific properties of heat may be classed under two heads: its tendency to diffuse itself equally among bodies, or its mode of communication from one body to another; and the peculiar manner in which it passes through bodies. Whatever be our opinion respecting the real nature of heat, it is almost impossible to enter into any investigation concerning it, without using language that would seem to imply, that it proceeds from the operation of a material cause. If, therefore, we fall into these forms of expression, it must be ascribed, not to our decidedly adopting this hypothesis of the nature of caloric, but to the extreme difficulty of avoiding them, although they must be admitted to be incorrect. With this preliminary caution, we may be allowed to say, that heat differs from other bodies, in its tendency to diffuse or distribute itself uniformly through all kinds of matter. When any substance possesses a different portion of free caloric from the substances in its vicinity, either in immediate contact, or connected with it by the intervention of a third substance, the superabundant portion of heat will have a tendency to pass from the first to the second, and the one will give and the other receive heat, until they arrive at a common temperature. This is one of the most familiar occurrences, and one of which we perpetually avail ourselves in the arts of life. If we wish to impart heat to a body, we bring it near a substance that is hotter than itself, when it immediately begins to receive heat, and continues to acquire it, as long as it remains in its new situation, or until it shall have experienced some change, which renders it incapable of the farther reception of heat. When, on the contrary, we wish to cool a body, we remove it into the neighbourhood of one which is cooler than itself, when an operation the reverse of the former will ensue; the cold body will abstract heat from the warmer, until the common temperature be gained.

The cause of this tendency in heat to fly off from bodies, or to pass from one to the other, and thus to diffuse itself among them, is attributed to its possessing an inherent repulsive power. The particles of all kinds of ponderable matter are necessarily attracted to each other, and consequently, under all circumstances, they have a tendency to be drawn and held together, unless some counteracting cause prevents their union. This is equally exemplified in the attraction which prevails between large masses of matter, by which the planets are kept in their orbits, called the attraction of gravitation, and the attraction which exists between the individual particles of matter, and influences many of the minute operations of nature, under the denomination of chemical attraction. The repulsive power, which appears to be an inherent quality of heat, may be regarded in general as the cause of its diffusion among bodies; but the manner in which it is distributed, or the particular law which it follows in passing off from one body, and attaching itself to others, seems to depend upon a different principle, or at least to be modified in a way that cannot be referred to repulsion. It has been conceived, that the phenomena might be explained upon the idea, that there is a combination of the two powers of repulsion and attraction, the heat escaping from a body, in consequence of the repulsive power that exists between its particles, while, at the same time, it is attracted by the particles of the body into which it enters. And perhaps this kind of double operation will serve to explain most of the facts, or at least will enable us to announce them in language which implies no contradiction, and gives an idea of their relation to each other. The equal distribution of heat, as it has been called by some writers, or the equilibrium of caloric, as it has been styled by others, constituting one of the specific properties which we enumerated above, has been the subject of much observation and experiment, and has also given rise to much hypothetical discussion.

The law by which bodies of different temperatures become the one hotter and the other colder, or by which the equilibrium of heat is produced, was first laid down by Newton, and may be thus expressed in general terms; that the heat lost by the one body, and gained by the other, is in proportion to the excess of the temperature of one above the other; or, stating it in a more scientific manner, that the difference between the temperatures diminishes in a geometrical ratio, while the times increase in an arithmetical ratio. The external circumstances which influence the rapidity of the equalizing process, are the radiating power of the bodies themselves, their conducting power, and, provided they are not in contact, the nature of the medium which is interposed between them, and the mechanical changes which take place in the medium, relative to its position with respect to the heating and cooling bodies, constituting currents. These principally operate in what are styled the elastic fluids; but they have also considerable effect in the action of liquids. The hypothesis which is commonly adopted, and which appears satisfactorily to account for this peculiar property of bodies, was proposed by M. Prevost. It is founded upon the following data. Heat is conceived to be a fluid, composed of distinct particles, which pass through space in right lines, and are projected in all directions, with very great velocity. The particles are so far removed from each other, that, analogous to what takes place with respect to light, a number of currents may flow in different directions, without interfering with each other. All bodies, except such as we suppose to be absolutely deprived of heat, send out rays to each other, although generally in very different degrees. Two bodies, exactly of the same temperature, will mutually give and receive heat, and even a cold body will radiate heat to a hot one; but, in the former case, the quantities given and received by each will be exactly the same, so that the temperature will not be changed; and, in the latter case, the one will give much more than the other, until the temperature of the two is equalized. *Phil. Trans.* 1802, p. 443.

This hypothesis appears to have been originally formed, in order to account for the experiment of which we gave an account above, the radiation of cold. When a heated body parts with its caloric to the neighbouring bodies, and raises their temperature, the idea that presents itself, as the most natural explanation of the fact is, that the hotter body has merely given off its superabundant heat to the colder, in consequence of the tendency which heat has to distribute itself uniformly through all bodies subjected to its influence. It may be conceived in this case to pass off, in a greater or less degree, according to the excess of the temperature of the one body over the other, modified by the nature of the surface, and the other circumstances to which we have already alluded. But this simple view of the operation will not explain the radiation of cold, or at least will not explain the apparent reflection of it from a concave mirror. If the cold body acted only by attracting heat from the neighbouring bodies, it would take it from the thermometer, the mirror, and all other contiguous substances; and there seems to be no reason why the focus should be colder than any other part of the atmosphere, equally near the source whence the cold proceeds. According, however, to Prevost's notion, when ice is placed in one of the foci, it sends out radiant heat, which strikes against the mirror, and is reflected into the opposite focus; but these rays being comparatively colder than those which proceed from other bodies in the vicinity, have the effect of generating absolute cold in the second focus, and thus tend to depress the thermometer which is suspended there. A mutual exchange of heat thus takes place between the ice and the thermometer, and the equilibrium is established, by the ice acquiring, and the thermometer losing, each a portion of caloric. (*Journ. Phys.* t. xxxviii. p. 3.) The facility with which this hypothesis explains the radiation of cold, is itself an argument in favour of its validity; and it must be admitted, that it applies equally well to all the other phenomena in which caloric is concerned. An objection has indeed been urged against it, that it does not take into account the effect of the conducting power of bodies, which must have an important effect in the equalization of their temperature. This is not, however, properly an objection against the general doctrine of the reciprocal interchange of radiant heat, but an omission in Prevost's manner of applying it; and it seems that the two operations are not in any degree incompatible with each other. Still, however, M. Prevost's opinion must be regarded rather as a plausible conjecture, which has the merit of satisfactorily explaining the phenomena, than as a theory founded upon any direct experimental proofs. It has indeed been conceived, that Professor Leslie's researches afford considerable support to it, as they tend to establish the existence of a radiating energy in bodies, quite independent of their conducting power; an energy, by which even the worst conductors of heat, under certain circumstances, become the most active radiators of it. Yet this radiation can never be proved to exist, except there be a previous difference of temperature between the bodies; because the thermometer, which is our only measure of heat, and the only index which we possess of its presence, is never affected except by an unequal distribution of it.

Having now described the manner in which heat tends to pass from one body to another, we shall next proceed to the second of its specific properties, the power by which it moves among the particles of the same body; or is conducted, as it is styled, through their substance. As bodies appear under the three states of solids, fluids, and gases, we should consider the power which heat exercises in its transmission through each of these different forms of matter. Our remarks will, however, be chiefly confined to the action of solids and liquids upon heat; for in consequence of the tenuity of gases, or the distance at which their particles are situated from each other, it does not appear that any very notable effects can be attributed to them upon the passage of free caloric, at least in comparison with what we observe in the two other classes of bodies.

When heat, in its uncombined state, radiates through air, or through a vacuum, it moves with a velocity which has not been accurately measured, but which, there is reason to suppose, is immensely great; so that, with respect to any distances near the earth, it may be said to be infinite. Heat also passes through the most dense and solid bodies, as, for example, through metals; but in this case its progress is prodigiously retarded. It is also found to move through these bodies with various degrees of velocity, which do not seem to bear an exact ratio to any other of their properties, and which can only be ascertained by direct experiment. This, in opposition to the rapid transmission of heat through the air, or through a vacuum, has been styled its slow communication; and the power which solids possess, of enabling heat to pass along them, has been called their conducting power. When solids are in contact, and are possessed of different degrees of heat, they immediately tend to produce an equilibrium of temperature; which is not brought about, as in the former case, by radiation, but by the one directly abstracting a portion of heat from the other, conducting this portion through its own substance, and diffusing it equally among its particles. This faculty exists in bodies in very different degrees; but it is found that each individual body always preserves the same degree of this power, unless some change takes place in its chemical or physical condition, when a change is at the same time produced in its conducting power. A familiar but a correct example of the different degrees of this conducting power in bodies, may be noticed in the different effects that are produced upon metal and upon glass. If a rod of each of these substances have one of its ends plunged into hot water, the metallic rod will soon become so thoroughly heated, through all its extent, that it will be impossible to apply the hand to the other extremity, while the glass rod will remain a long time in the water, before the upper end is sensibly affected. Hence we say, that metals are good conductors of heat, and that glass is a worse conductor of heat than metals. As a general principle, it may be stated, that the densest bodies are the best conductors; but to this rule there are many exceptions. Upon the whole, however, the principle seems to hold good in so many instances, that we may infer the existence of a necessary connexion between the density and the conducting power of bodies, and that when the ratio is not correctly maintained, it should be attributed to the interference of some other principle. Thus it is remarked, that the same body, without having experienced any chemical, or any other physical change, except a difference in its state of aggregation, has its conducting power increased or diminished, in proportion to its density, or to the contiguity of its particles. Rumford found that a solid piece of iron is a better conductor than the filings of the same metal; and that wood is a better conductor than saw-dust.

Many experiments have been performed on the conducting power of solids, the object of which was to ascertain the amount of this power, and to learn whether it bore an exact ratio to any other physical or chemical property. Metals, as was remarked above, are some of the best conductors of heat, but they differ considerably among themselves in this respect. Ingenhousz instituted a simple, but ingenious process, for discovering their relative power, which consisted in providing himself with rods of different metals, all of the same diameter, and having a certain length covered with a coating of wax of the same thickness. The other ends of the roads were then plunged to the same depth in a heated fluid; and, according to the quantity of wax that was melted, their conducting power was estimated. The best conductors were found to be silver, gold, tin, and copper, while platina, iron, and lead, seemed to be the worst: (*Journ. Phys.* tom. xxxiv. p. 68.) These experiments prove that the conducting power of the metals is not precisely in the same ratio with their density. Richmann of Petersburg endeavoured to ascertain the same point by a different process. He procured hollow balls of the several metals; into these he inserted the bulb of a thermometer, immersed the balls in boiling water, and observed the effect upon the mercury: (*Comment. Petrop.* vol. iv. p. 241.) The results do not precisely agree with those of Ingenhousz; but although more elaborate, we think them less direct; because in Richmann's other causes besides the mere effect of the conducting power might act upon the thermometer, an objection which does not seem to apply to Ingenhousz's.

A set of interesting experiments was performed by Rumford on the conducting power of various animal and vegetable substances. The plan which he pursued was to provide himself with a glass cylinder, which terminated in a globe of somewhat more than an inch in diameter. The bulb of a thermometer was suspended in the centre of this globe, and was surrounded by the substance to be examined; and the whole apparatus was then plunged into boiling water, and when raised to a certain elevation of temperature, it was immersed in a mixture of ice and water, and the time noticed which was required to bring it down to this degree of heat. The heat from the water must obviously pass through the substance upon which the trial was made, before it could reach the thermometer; therefore its conducting power was estimated by the effect which it produced upon this instrument. He began by observing the length of time necessary for raising the thermometer enclosed in the cylinder, when it was surrounded only with air, and what length of time was also necessary to cool it, by afterwards immersing it in a mixture of ice and water. He then successively introduced into the globe, similar weights of wool, cotton, silk, linen, down, and fur, and compared their effects with air, taken as a standard; the two last bodies were found to be the worst conductors, and linen the best, a fact which agrees with our experience of their effect when used as cloathing; for we know that their only operation, as producing warmth to the body, must depend upon their retaining the heat which is generated in it, and preventing its escape. The Count concludes, that the relative conducting power of these substances was in the inverse ratio of the quantity of air interposed between the particles or fibres of which they are composed. He found that their non-conducting power was not in proportion to the quantity of solid matter which they contain, and therefore could not be from any mutual attraction between the solid matter and the air; for the power bore no ratio to the actual quantity of the substance, but obviously depended upon the manner in which it was arranged.

He performed a direct experiment on silk, which establishes this point. Equal quantities of raw silk, the ravellings of spun silk, and twisted silk thread, were respectively placed in the apparatus; and their conducting powers were found to be in the proportion of 9, $11\frac{5}{2}$, and 13. He afterwards examined how far the air itself in the globe and cylinder might be conceived to be the sole agent, when it appeared, by calculating the space which the different substances occupied, and comparing the effect of the bulk of air which would be left, with the effect of the instrument when entirely filled with air, that the process of cooling was retarded by the mixture of the body with the air; and hence he deduced the conclusion, that the presence of the solid matter impedes the motion of the air, and prevents those currents from being formed in it, which we shall afterwards find to act so important a part in the heating and cooling of fluids: (*Phil. Trans.* 1792, and *Essays*, vol. ii. p. 428.) At the time when Rumford published his Essay, the effect of the radiation of surfaces was not thoroughly understood, and it is entirely neglected in the view which he takes of the subject. It must, however, have had a considerable share in the production of the phenomena; and we may imagine, that the more the particles or fibres of the solid matter are dispersed through the mass of air, the greater number of rays will be interrupted by them. It is also probable there is a real attraction between air and the different substances that were examined, which must have had its share in affecting the nature of the results; but whether the attraction differs in different substances, or whether the attractive power of the air is precisely equal upon all of them, does not appear to be exactly ascertained. Some experiments were made by Meyer of Erlangen, on the conducting power of the different kinds of wood. He procured balls of them, in which he formed a cavity to receive the bulb of a thermometer; the balls were then exposed to the same temperature, and the effects upon the mercury were noticed. The experiments, although performed with apparent accuracy, are defective in not making any allowance of the action of radiation. Lime, fir, alder, and oak, were the worst, while ash, apple, and ebony, were found to be the best conductors of heat. *Ann. Chim.* t. xxx. p. 32.

The different conducting power of bodies produces a great difference in their action upon the nerves in exciting the sensations of heat and cold, although the bodies indicate the same temperature to the thermometer. Thus it is well known, that in the same apartment, when it contains no source of local heat, the different articles of furniture will convey to the hand very different degrees of warmth. Metals feel the coldest, stone or marble is the next in degree, while wood, and still more woollen stuffs, produce little or no feelings of any change of temperature. The effect in this case depends upon the different conducting power of these substances; the human body being almost always warmer than the objects that are contiguous to it, its heat is abstracted by them; but this operation goes on in proportion to their conducting power, *i. e.* to the respective velocity with which they are enabled to remove the heat from our body. It obviously follows, that when we wish to retain the heat in any substance that is warmer than the surrounding medium, we must enclose it in bad conductors of heat; and that exactly the same method must be pursued, if we wish to keep any substance at a lower temperature than the atmosphere, or other contiguous bodies. Thus we envelope ourselves in woollen cloth or furs when we wish to retain our natural warmth; and we should employ the same method to prevent the melting of ice or snow.

We have already observed that one cause, which obviously tends to affect the conducting power of bodies, is their possessing a spongy texture, by which portions of air become, as it were, entangled in its pores, and thus seem to prevent the communication of heat. But we observe a very marked difference in the conducting power of bodies that are perfectly solid, and where no air, or at least no quantity that can be supposed capable of producing any effect of this kind, is present. What is it, in this case, that causes the difference in the conducting power of bodies? Is it an attraction which the heat possesses for the particles of the solid, or do the experiments of Rumford and others lead us to regard the operation as of a more mechanical nature, as if there was something in the arrangement or shape of the particles, which retards the passage of the heat along them? These are questions which at present it appears to be beyond our power to answer. Those cases in which a greater or less degree of density, or of aggregation of the parts of bodies, produces a considerable effect upon their conducting power, would induce us to suppose, that the worst conductors should be regarded as merely the most effectual retarders of heat, and the best conductors as simply those that have the least power in retaining the heat that has been imparted to them. But this view of the subject seems scarcely to apply to metals and other solids of a similar kind. The radiation of the surface may be supposed to have some influence in these cases; and M. Poisson goes so far as to conjecture, that the conducting power of solids, generally, is to be regarded as a kind of radiation from particle to particle, operating at very small distances: (*Journ. Phys.* t. lxxx. p. 434. *et seq.*) Upon this point, however, it does not appear that we have any data which can enable us to form a decided judgment.

Without, however, entering upon any abstruse theory on the subject, for which the present state of our information does not seem to afford a sufficient foundation, we may assume, as the most natural deduction from the facts, that the conducting power of bodies depends principally upon three circumstances. It is affected partly by the mechanical relation of their particles to each other, partly by an attraction between the heat and the particles of which the body is composed, and partly by the radiating power of the heat. The heat which escapes from the surface will tend to draw from the interior a portion of its remaining heat, in order to supply what has been lost from the external parts. There are also other causes, which, although perhaps less efficacious, are not to be neglected. The consequence of adding heat to a body is, to expand it in all its dimensions; but, by this expansion, it appears to acquire a greater capacity for retaining heat, so that it will become more disposed to carry it from other bodies, and to diffuse it over its own substance, and thus to have its conducting power increased. The effect which caloric has in altering the state of bodies, may likewise materially affect their conducting power, according to the nature of this change. Thus, if we throw a certain quantity of heat into a metal, it is reduced to the fluid state, by which its relation to heat, and the manner of conducting it, will be much affected. There is some reason to suppose, from an experiment of Pictet's, that heat passes more readily upwards than in the contrary direction. He enclosed a metallic bar vertically in a vacuum, and, heating it exactly in the centre, observed the effect produced upon thermometers attached to each end; when it appeared, that the one at the upper end was affected sooner than the one at the bottom: (*Essay on Fire*, § 33.) The experiment is ingenious: but there are some points connected with it, which render the result rather dubious.

We now proceed to consider the manner in which heat passes through fluids. Fluids differ essentially from solids in their particles being movable among each other; and this circumstance, as we shall find, acts a very important part in the transmission of heat. Fluids, like solids, are expanded by caloric, and of course become specifically lighter; and therefore, when heat is partially applied to them, in consequence of this alteration of gravity, the parts change places with respect to each other, the lighter or heated part rises to the surface, while the colder part sinks to the bottom. It is obvious, then, that heat may be supposed to pass through fluids in two ways; it may either be transmitted from particle to particle, as is the case with solids, or it may be conveyed by a change of gravity in the substance itself, producing a species of circulation among its parts. Many facts that fall under common observation, shew that this circulation takes place in partially heated fluids, and prove that it is much easier to cause heat to pass upwards through them, than in the contrary direction; but the impossibility of heat being propagated downwards through fluids, was not admitted until after the experiments of Rumford. These experiments, which are perhaps the most ingenious of any which he ever performed, have been generally regarded as sufficient to prove the general principle to which we have already alluded, that when any portion of a fluid is heated beyond the temperature of the remaining part, it rises to the surface, in consequence of its comparative levity; and if the heat be applied to the bottom of the vessel, which is usually the case, the successive portions of the fluid, as they receive the heat, rise in their turn to the upper part, until the whole acquires one uniform temperature. On the contrary, if the heat be applied to the top of the fluid, it is only the upper stratum which becomes heated, the remainder retaining its former temperature. Rumford placed a portion of ice on a certain quantity of boiling water, and found that it was melted in about 3 minutes; but when the same substances and apparatus were used, except that the ice was fixed at the bottom of the water, several hours elapsed, and yet the ice was not completely thawed. To render the operation still more striking, it was so managed that water was made to boil in the upper part of a cylindrical vessel, while the lower part remained full of ice. *Essays*, vol. ii. p. 241, *et seq.*

We have already mentioned the experiments in which it was found that heat passed less readily through solids, when they were of a spongy or porous texture, than through those that were more dense and compact. The same kind of effect was found by Rumford to take place in fluids when substances were mixed with them, which, by their viscidity, or other analogous property, would prevent the motion of their particles, and thus put a stop to the circulation, which we have described as conveying the heat through their different portions. He compared the time which was necessary for a quantity of pure water to change its temperature, by a certain number of degrees, with the same bulk of water when mixed with down or with starch; and he found the times to be as the numbers 6, 9½, and 11. He afterwards went on to shew, that, by increasing the quantity of matter in the fluid, the difficulty of the passage of heat through it was proportionally increased. $\frac{1}{50}$th part of its weight of down added to water produced a retardation equal to 75, while $\frac{1}{12}$th of the same substance produced an effect equal to 95: (*Essays*, vol. ii. p. 221. *et seq.*) The general principle, therefore, appears to be fully established, that fluids transmit heat, or suffer it to pass among their parts, in a different way from that in which heat is transmitted through solids, not by its being given off from one particle and received by another, but by all the particles coming successively to the source of caloric, and individually receiving it from the heating body. Whatever impedes the intestine motions of the fluid, and prevents this circulation of its particles from taking place, stops the passage of heat through it, and confines its effect to the portion which first received it.

The facts brought forward by Rumford may be considered as very decisively proving the general principle; but it has still been questioned, whether there is in fluids that absolute and complete non-conducting power which he attributes to them. Some experiments to prove that they really possess a small degree of a proper conducting power, have been performed by Dr Hope, Mr Nicholson, Mr Murray, Dr Thomson, and Mr Dalton. Their plan was to communicate heat to fluids in a direction different from that in which the supposed currents would act, as by applying it to the upper surface, and by their using every precaution to prevent its being carried downwards by the sides of the vessel containing the fluid, or by any other counteracting cause. The experiments appear, upon the whole, to prove their position, and thus to modify the conclusions of Rumford; but perhaps in all of them there may still be some sources of inaccuracy, which it is very difficult to guard against. The process of Mr Murray appears, upon the whole, to be the most unexceptionable. He formed a hollow cylinder of ice, which served as a vessel in which to contain the subject of his experiment; for ice, as long as it remains unmelted, being a perfect non-conductor of heat, the objection must be removed, which depends upon the conducting power of the vessel itself. The other arrangements made by Mr Murray were very ingenious, and appear to be well adapted for preventing the passage of heat in any manner except through the actual fluid; yet heat seemed to be certainly transmitted from the upper surface to the lower part, so as to affect a thermometer fixed near the bottom: (Nicholson's *Journal*, vol. i. p. 421.) If, then, we are brought to conclude, that fluids possess some degree of conducting power, it next remains for us to inquire, what is the relative degree in which it exists in different kinds of fluids? This, however, is a question, which it is impossible for us to answer with any accuracy; because we have no correct means of learning how far the communication of heat to them depends upon their proper conducting power, and how far upon the motion between their particles. It may be inferred, from some experiments of Rumford's, that mercury is a better conductor of heat than oil or water; and this might be expected to be the case. It is natural to suppose that mercury, so far as it is a fluid substance, conveys caloric, by internal motions among its particles, like other fluids, yet that it still retains its metallic property, and may conduct it from particle to particle.

The subject of the conducting power of liquids has very recently been investigated by Dr Brewster, who has removed every doubt that could remain respecting the existence of this property in fluid bodies, and has pointed out a simple method, by which the conducting power of all transparent fluids may be rendered visible to the eye, and easily measured, without the aid even of a thermometer. The apparatus by which these experiments were made is shewn in Plate CCLXXXIX. Fig. 8. where ABCD is a tin vessel about a foot long, having two openings E, F, in which two pieces of parallel glass are firmly cemented. A heated iron GH is suspended by a wire LM, and a stand RT, having a small circular aperture P, about one-eighth of an inch in diameter, is placed very near the plate of glass F, so as to be seen distinctly by an eye at E. This aperture is capable of being raised and depressed by a finger screw S. The vessel is now filled with water, or any other fluid, nearly to the top, and the eye being placed at E, and the aperture P raised so as to be seen through the upper stratum of fluid, it will appear of a perfectly circular form. Let the heated iron be now suspended, as in the Figure. In a few seconds the upper stratum of fluid will expand, as the heat penetrates the mass, and the circular aperture will have an elliptical form, as shewn at *a*, Fig. 9. By depressing the aperture P, so as to allow the rays which diverge from it to traverse the fluid strata at different depths, the aperture will have the appearance shewn at *b*, *c*, becoming perfectly circular at the point *c*, to which the heat has advanced. These appearances are the necessary consequence of the propagation of the heat downwards, which diminishes the density, and consequently the refracting power of the upper strata. A very curious phenomenon now takes place upon removing the hot iron GH. The uppermost stratum *m n*, Fig. 9. which was formerly the hottest and the least dense, now gives out its heat to the superincumbent air, and to a certain depth *c*, Fig. 10. the fluid diminishes in density, while from *c* to *f* its density increases. If, in this situation, we again examine the circular aperture, it will be found to be extremely elliptical at *a*, Fig. 10. having its larger axis horizontal. The ellipticity will gradually diminish towards *c*, where its form will be circular, and below *c* it will again become elliptical, the larger axis of the ellipse being now in a vertical direction. In these experiments the heat propagated down the sides of the vessel produced no effect, and if it had produced any, it could have been easily distinguished from that which was occasioned immediately below the hot iron.

Now, as all these changes are capable of being accurately measured by a micrometer, we are furnished with the means, not only of ascertaining the relative conducting powers of all transparent bodies, but also of determining the curve of density, whether the variation of refractive power is produced by heat, by pressure, or by the mutual penetration of two different fluids. The optical properties which were developed during these experiments, will be explained in our article OPTICS. Similar results may be obtained in a manner very different, but equally satisfactory. Let AB, Fig. 10. No. 2. be a vessel having a plate of annealed glass, whose section is MN, placed horizontally near the surface *m n* of the fluid, and supported by a glass pillar P. When this vessel is properly exposed to polarised light, no appearance will be seen through the edges MN of the glass; but if a heated iron is suspended, as in Fig. 8. the descent of the heat towards the surface MN, and its propagation through the glass plate, will be marked by beautiful fringes of light parallel to MN. Hence we have another method, and a very direct one, of *measuring the conducting powers either of transparent or opaque bodies*, by the Chromatic thermometer. See GLASS, THERMOMETER; and the *Phil. Trans.* 1816. p. 108.

We have but few remarks to make on the manner in which heat is transmitted through gases. From their physical constitution, especially from the facility with which their particles move among each other, we might infer that heat would be conveyed through them, more in the way that it is through fluids, by the action of currents, than from particle to particle, as in solids. We know also that air, like liquids, is expanded by heat, and that this expansion causes it to become specifically lighter, and thus forms ascending currents of warm, and descending currents of cold air. Rumford endeavoured to prove by experiment, that the passage of heat through air was entirely brought about by these currents, and that it was in itself a perfect non-conductor. (*Essays*, vol. ii. p. 410. *et seq.*) But his experiments, and the reasoning founded upon them, although ingenious, do not decisively prove the point; they only go so far as to show, that whatever impedes the motion of the air, retards its heating and cooling, and that the communication of heat to air is, in part at least, effected by the same means as it is in fluids. Berthollet has indeed advanced some considerations in favour of an opinion the very opposite to that of Rumford's, that air is a good conductor of heat, (*Stat. Chim.* tom. i. p. 467,) but they cannot be considered very decisive, and, in short, the question must be regarded as one which is still open to further discussion.

Before we conclude the subject of the properties of heat, we must make a few remarks upon the cooling of bodies. This process depends upon the combination of a variety of circumstances; partly upon the tendency to radiation, partly upon the conducting power of the substances in contact with the body to be cooled, and partly upon the presence of those currents, which we have described as existing in fluids and gases. Professor Leslie, in the course of his researches, to which we have so often alluded, made some experiments on the cooling of water contained in vessels that had differently radiating surfaces. He found that a globe of polished metal, when filled with boiling water, cooled to a certain degree in 156 minutes, while under the same circumstances, except that the globe was coated with lamp black, the water required only half that time for cooling. In this experiment, however, the cooling depends partly upon radiation, and partly upon the conducting power of the substance of which the vessel is formed; and Professor Leslie attempted to estimate the relative effect of these two operations. From previous trials, he knew what quantity of heat would have been abstracted by radiation alone; and thus it was easy to calculate what portion of the heat was removed by radiation, and what by the conducting power of the vessel. The general result is, that the effect of radiation is more powerful than that arising from the conducting power; for the lamp black, which is known to be a bad conductor, increases the cooling of the water by augmenting the radiation. As might be predicted, from what has been already related, when the globe was immersed in water, the cooling went on at the same rate, whether the surface was clean, or was covered with the black paint. In this case the process depended entirely on the internal currents that were formed in the water, while the surface of the vessel has no effect upon it. *Inquiry*, p. 268. 316.

Both Professor Leslie and Count Rumford performed a number of experiments, similar to the one mentioned above, on the action of the surfaces of vessels in promoting or retarding the escape of heat from bodies contained in them. We arrive at many conclusions which are singular and important; but they so obviously follow from the facts which have been already noticed respecting the radiation of heat, that it will not be necessary to dwell very long upon them. In Professor Leslie's experiments, it was always found that the cooling of water in metallic vessels was accelerated by coating the vessel with paper, paint, isinglass, or other similar substance; and while the coating was comparatively thin, this acceleration appeared to be in proportion to its thickness. So that although in these cases the conducting power must have been injured, yet this defect was more than counteracted by an increase of radiation. It can, however, scarcely be doubted, that were we to go beyond a certain limit, we should find, that, by augmenting the thickness of the coating, the diminution of the conducting faculty would prevail over any advantage which might be derived from the increase of the radiating power. There are several reasons which induce us to suppose that this latter quality is effected principally by the nature of the surface, while the conducting power must depend equally upon the nature of the substance through its whole thickness. It does not appear that any experiments have yet been performed, by which we can learn in what point this balance of power exists. Rumford's general conclusions entirely coincide with Professor Leslie's. He found that the same metallic cylinder, which, when filled with water, required 55 minutes to cool through a certain number of degrees, required only 43 minutes when covered with a layer of glue, 36 when covered with linen, and 34 when coated with a varnish of lamp black. *Phil. Trans.* 1804, p. 90.

When bodies are surrounded either by a fluid or by air during their cooling, the rate of the process will be considerably affected by the motions that take place among the particles of the investing medium. The action of a current of air in promoting refrigeration is too well known to require illustration; and this must evidently be an effect entirely independent of radiation, and in a great degree, at least of the conducting power of the air. Without deciding the question, whether air be an absolute non-conductor, it is rendered probable, both from circumstances that fall under daily observation, as well as from the direct experiments of Rumford and others, that air is not a good conductor of heat, and that one of the most effectual methods of retaining the temperature of a body, is to surround it with a stratum of air, so confined, that no internal motion can take place among its particles.

Hitherto heat has appeared only as a simple substance, capable of being communicated through the parts of solid bodies with different degrees of velocity, according to their conducting power; the presence of the heat being in every case marked by an expansion of the solid body corresponding with the temperature. These views, however, though universally received both among chemists and natural philosophers, have been completely disproved by some recent experiments made by Dr Brewster on the propagation of heat along glass, obsidian, semiopal, muriate of soda, fluor spar, alum, gum copal, rosin, horn, amber, tortoise shell, and other substances. We shall endeavour to lay before our readers as brief and perspicuous an account as we can of the new properties of heat which were discovered in the course of these experiments, without anticipating any of the phenomena, which more properly belong to the subject of optics.

Let a plate of glass, ABDC, (Plate CCLXXXIX. Fig. 1.) having MN (Fig. 2) for its section, be placed with its edge CHD upon a hot iron, or be in any way exposed to a source of heat. The heat will be slowly communicated through the substance of the glass in the direction HGFE, and when the heat has reached E, the temperature will be greatest at H, diminishing gradually towards E. The glass will, therefore, according to the common doctrine, be in a state of expansion, as shewn in Fig. 3. being most dilated at H, and least dilated at E. The case, however, is very different. When the heat has entered the glass at the edge CD, the parts of the glass between the edge and the dark line at G are in a state of expansion, diminishing towards G, and at the same instant the parts of the glass between E and F are thrown into a similar state of expansion, while the intermediate portions between F and G are thrown into a state of contraction, the lines AFB and CGD being the limits between the contracted and expanded portions, where the glass has suffered no mechanical change. These opposite effects, which are shewn in Fig. 4. are distinctly produced before the heat has reached the point F. When the height of the glass plate HE is very small, EF is equal to HG, and the contractions and expansions are almost simultaneously produced; but when HF is two or more inches, EF is always much greater than HG, and the expansion between E and F is less distinctly seen, being spread over a greater space. From these results it follows,

1. That heat, in passing along a plate of glass, *expands a part of the glass, where the heat does not exist in a sensible state.*

2. That the heat also *contracts an adjacent portion of the glass, where it does not exist in a sensible state.*

3. That the heat *contracts a part of the glass, where it does exist in a sensible state.*

4. That the heat *expands an adjacent portion of the glass, where it does exist in a sensible state.*

If the plate of glass ABDC, instead of being heated, is brought to an uniform temperature by immersion in boiling water, and is then allowed to cool in the air, all the effects, which we have described, are exactly reversed during cooling, as shewn in Fig. 5. the parts of the glass which were formerly contracted being now expanded, and *vice versa.*

If the expansion between H and G is either increased or diminished by a variation in the source of heat, the other expanded and contracted portions suffer a similar change; so that there must always be an equilibrium among the forces, by which these opposite mechanical states are produced.

Let the plate of glass ABDC, Fig. 6. be cut with a diamond through its centre O, by a line MN, but not separated into two parts, and in this state let it be placed with its edge CHD on a hot iron, as before. It will now exhibit the very same phenomena as those which we have already described, just as if it had never been touched with the diamond. When it is in this state of contraction in the middle, and of expansion at the edges, let it be suddenly broken through at the line MON, and it will be found that each of its halves ABNM, MNDC, Fig. 6. are thrown into the same state of contraction and expansion as when the plate was unbroken. Between E and *f*, *g* and O, O and *f'*, *g'* and H, the glass will be expanded, while between *f* and *g* and *f'* and *g'* it will be contracted, as shewn in Fig. 7.

Hence, it is obvious, that the contraction and expansion, or rather the phenomena by which they are indicated, are produced by some fluid, which is decomposed by heat into two fluids possessed of opposite polarity, in the same manner as the electric fluid of the tourmaline is decomposed by the action of heat, or the magnetic fluid of a piece of iron by the action of a loadstone. All the phenomena, indeed, which are exhibited during the passage of heat through a plate of glass, are *precisely the same* as the phenomena which take place in the communication of magnetical and electrical polarity; and if we admit the existence of two fluids as the agents by which the phenomena of electricity and magnetism are produced, we are compelled to make the same admission in the case of the propagation of heat along glass. It is not unlikely that the phenomena may be produced by the mutual action of free and latent heat. In our article Optics we shall have occasion to resume this subject at great length, and to give drawings and descriptions of the various optical phenomena which are produced by the singular state, into which glass and other bodies are thrown during the propagation of heat through their substance. Those who wish for full information on this subject may consult the *Philosophical Transactions* for 1816, part i. p. 46—114, and 156—179.

## SECT. II.

### *The Effects of Heat.*

We now arrive at the second of the great divisions into which we proposed to arrange our materials, the effects of heat. The principal of these are four. 1. Temperature, or the production of the sensation of heat; 2. Expansion, or the simple augmentation of the bulk of a body, without altering its condition; 3. A change in the physical state of a body, by which a solid is converted into a fluid, and a fluid into a gas; and, 4. Ignition, or the operation of heat, by which a body is rendered luminous.

1. Temperature is often used rather as a generic term, applicable to all the phenomena that bear a relation to heat, than as a specific term, proper to designate any one of them in particular. It is, however, not unfrequently used to express the power of exciting the sensation of heat, or the effect which it produces on the animal body; and there seems to be some propriety in establishing this restriction, because the word heat, which might otherwise be employed, as we have already remarked, is liable to the objection of being sometimes used to express the *cause*, and at other times the *effect*. The temperature of a body varies according to the quantity of heat which it contains, and may be said to be in the direct ratio of this quantity, although the indication of temperature, which we derive from the sensations, is much too vague to enable us to lay down an exact scale of admeasurement. This proportion of effect, however, only applies to the same body, or to those of a similar kind; for it has been found that the same quantity of heat affects the temperature of different bodies in very different degrees. These different effects depend partly upon the capacity of bodies for heat, and partly upon their conducting power; a point to which we have already referred in a former part of the article. The sensation of temperature is also very much influenced by the state of the nervous system, independent of the quantity of heat in the substance exciting it. It is well known that, when the hand is cold, a body that is applied to it will appear hot, when the same body would excite the sensation of cold, had the hand been previously exposed to a higher temperature. This sub-

ject belongs more to physiology than to natural philosophy in general; we shall therefore only remark, that we seem always to compare our present feelings with our former ones, and to refer our sensations, not to any invariable standard, but to what we have felt just previous to the present impression.

2. The effect of heat upon the sensations, although the one which must have been first attended to, and that which constantly offers itself to our observation, is found to be so inaccurate as a measure of its quantity, that we always have recourse, for this purpose, to the second of its effects, which we enumerated above, expansion. According to one of the characters of heat, which we have already described, that of distributing itself equally among bodies whenever two substances are brought together, which differ in their temperature, the one gives off a portion of its heat to the other, and that which receives it becomes expanded, or has its bulk increased in all its dimensions. This expansion continues as long as the body in question maintains its elevated temperature; but when the heat is withdrawn, it begins to contract, and by degrees it acquires its former bulk. This expansion occurs, with very few exceptions, in all bodies; but it differs extremely in degree. It is by much the greatest in aeriform fluids of all kinds. It is less in quantity, although still considerable, in liquids; while in solids, it is so small as not to be perceived, except by the intervention of an apparatus expressly contrived to render it visible. Not only these general classes of bodies, but many of the individual substances comprised under each of them, have very different degrees of expansive power, which has been frequently made the subject of experiment.

The different gases have been submitted to numerous trials, for the purpose of ascertaining their relative expansion. Priestley paid a good deal of attention to the subject. It was farther investigated by Roy, Monge, and Saussure; and lastly, with much apparent accuracy, by Guyton. (*Ann. Chim.* t. i. p. 256. *et. seq.*) Their results, although various, agreed in the main conclusion, that each of the gases had a specific power of expansion peculiar to itself, and which is uniform for each of the gases at the same temperature. But, notwithstanding the weight of these authorities, a farther examination of the subject by Mr Dalton and M. Gay-Lussac has led to an opposite conclusion, that all the aeriform fluids suffer the same expansion from the same addition of heat. Mr Dalton's experiments indicate, that 100 parts of any gas, in passing from the freezing to the boiling point, increase to 137 parts, which is nearly $\frac{1}{480}$ for each degree: (*Manch. Mem.* vol. v. p. 598.) M. Gay-Lussac's experiments were published a short time subsequent to those of Mr Dalton; but being made without concert or co-operation, they are to be regarded as equally original, and they lead to conclusions so nearly similar, as to afford the strongest evidence of their correctness. (*Ann. Chim.* t. xliii. p. 137. *et. seq.*) The source of error in the experiments that had been performed, previous to those of Dalton and Gay-Lussac, appears to have arisen from a quantity of aqueous vapour that had been mixed with the gases. See Expansion.

The expansion of liquors by heat differs, in many respects, from that of gases; it is less in amount, it varies much in different fluids, and it is found not to be in proportion to the quantity of caloric that is added to the heated body. If we observe the effects produced upon mercury, water, and alcohol, by the same addition of heat, and when they are all at the temperature of 50°, we shall find it to be, in the first of these fluids, equal to $\frac{1}{190}$ of its volume, in the second $\frac{1}{113}$, and in the last $\frac{1}{33}$. The comparative changes in bulk are also found to vary for the same fluid at different temperatures, contrary to what has been observed with respect to aeriform bodies, the expansion proceeding, in a gradually increasing ratio, as the temperature advances. Thus, at the temperature of 50°, the expansion produced by a single degree of heat is less than what would be produced by a single degree of heat at the temperature of 100°. Many accurate experiments, of which we have given an account in our article Expansion, were performed on this subject by Deluc. He found, that in fluids the rate of expansion is frequently irregular near the two extremes of freezing and boiling, and more equable in the middle of the scale; and hence he deduced a practical rule, that those fluids are the best adapted for measuring the degrees of heat, which have the largest interval between the limits of freezing and boiling. The general result of our examination of the expansive power of different fluids leads us to conclude that it has no connexion with their density, but it seems rather to be related to the quantity of heat necessary to convert them into the gaseous state. Thus ether is probably the most expansible, and mercury the least so, of any fluids, because they possess respectively the lowest and the highest boiling points. *Recherches*, t. i. p. 271, 311.

We have hitherto spoken of the expansion of fluids by heat, and their consequent contraction by cold, as of a property possessed by all bodies of this description; but there is one very remarkable exception to the general law, that of water. Water, through a certain range of temperature, like other fluids, experiences the usual augmentation of bulk by an addition of heat; but when it is cooled down to about 40°, it seems to arrive at its maximum of density; and if the cooling process be farther continued, it begins to expand, and continues its expansion until it arrives at its freezing point, when it becomes solid. By employing certain precautions, particularly by avoiding every degree of agitation, it will continue fluid for several degrees below the usual point of congelation, and it still goes on increasing in volume, until its actual solidification takes place. When a water thermometer, therefore, stands at 50°, it is impossible to know whether it be really at the temperature of 50°, or at that of 30°, 18° above, or two degrees below, its freezing point.

This anomaly, with respect to the expansion of water by the abstraction of heat, was one of the discoveries of the Florentine academicians, about the middle of the 17th century; but it was not much attended to, until it was again brought into view by Deluc. He repeated the experiment with more accuracy, and he attempted to ascertain the exact degree at which the expansion commences. This he fixed at 41°; and he farther discovered, that the expansion is nearly equal when water is either heated, or cooled, the same number of degrees above or below 41°: (*Recherches*, t. i. p. 225.) Some circumstances, which were not sufficiently attended to by Deluc, particularly the expansion of the glass in which the water is contained, were afterwards carefully noticed by Sir C. Blagden, and in consequence of these corrections, he fixed the point of greatest density at 39°. (*Phil. Trans.* 1788, p. 125, *et seq.*) Le Fevre-Gineau came to the same conclusion respecting this anomaly in the expansive power of water, by a very different process. He weighed a cylinder of copper in water at various temperatures, and thus obtained the weight of a cylinder of water exactly equal to that of the metal which he employed. The result of this process was to fix the maximum of the density of water at the 40th degree. Dr Hope adopted another method of arriving at the same conclusion, which we have fully explained in our article Expansion. Rumford has since performed a set of experiments upon the same principle, and with nearly the same results. There have been some objections made against these experiments, although they appear so correct, and were so much varied;

but, upon the whole, we conceive the conclusion to be thoroughly established, that the greatest density of water is at about 8 or 9 degrees above its freezing point. The cause of this peculiarity with respect to water is involved in considerable obscurity. It appears to be connected with the increased space, which water, as well as many other substances, occupy, when they assume the crystalline form; and we may conjecture, that some tendency to this state takes place in water before its actual occurrence. See Expansion.

The greater space which water occupies, when in the state of ice, has been long observed, and has been made the subject of some curious experiments, particularly by Major Williams, who, during an intense frost at Quebec, actually burst a cannon, by the freezing of only a comparatively small quantity of water: (*Edin. Trans.* vol. ii. p. 23. *et seq.*) When water is converted into the solid state, it forms spicular crystals, which cross each other at a determinate angle; and thus interstices are left, which cause it to occupy more space. Dr Thomson found, that the specific gravity of ice is to water at 60°, as 92 to 100; and hence we may conceive the great force that will be exerted, when water suddenly expands itself, so as to have its gravity diminished in the above ratio.

The expansion of solids, which we are now to consider, is much less than that of liquids. The same elevation of temperature, which increases the volume of a gas from 100 to 137 parts, increases that of a liquid only to about 104 or 105 parts, while it adds to a solid not more that $\frac{1}{1000}$ of its bulk. A set of experiments on the expansion of metals was performed by Smeaton, when he found, that, in passing from the freezing to the boiling points of water, platina was expanded from 100,000 to 100,087, gold from 100,000 to 100,094 parts, steel to 100,112 parts, copper to 100,170 parts, silver to 100,189 parts, tin to 100,288 parts, lead to 100.287 parts, and zinc to 100,296 parts: (*Phil. Trans.* 1754, p. 612.) It appears that the densest metals are generally the least expansible; but this proportion does not universally obtain.

The expansion of glass, which is a point of great importance to ascertain, as affecting the result of many other experiments, was made the subject of careful examination by Deluc. Supposing its bulk at 32° to be 100,000, at 212° it was found equal to 100,083, an expansion nearly the same with that of platina. From this estimate we learn that glass is expanded about $\frac{1}{200000}$ of its bulk by one degree of heat, and the expansion seems to be nearly uniform, for the same degree of heat, through the different parts of the scale. This equal augmentation of bulk, by equal increments of heat, is supposed to prevail generally in solids; but, from the minuteness of the effect, it is less easy to ascertain this point, than with respect to gases and liquids.

Several of the metals expand at the time they are converted from the fluid to the solid form; and this, as is the case with water, seems to depend upon the occurrence of a kind of crystallization, or regular arrangement of their particles. This is said to be particularly the case with respect to iron, and is the reason why we are able to take such accurate casts, when the melted metal is poured into moulds. It must, however, be observed, that the increase of bulk, which either water or melted metals acquire when they become solid, is no exception to the general law of expansion; for this applies solely to bodies as long as they retain the same state. The only anomaly, therefore, is the expansion of water while it remains fluid.

It is upon the expansive power which heat exercises over bodies that the thermometer is constructed; an instrument, as its name imports, employed for the purpose of measuring the degree of heat, or temperature of substances, to which it is applied, and which, considered in all its relations, may perhaps be regarded as the most useful agent in philosophical researches of which we are in possession. It appears to have been invented by Santorio, the celebrated Italian physician, who devoted so much of his attention to what has been called statical medicine. His instrument depended upon the expansive power of the air, and consisted of a tube, with a bulb of considerable size, the lower end of the tube being left open, and being plunged into a fluid, which was suffered to rise to a certain degree into the tube. As the air in the globe was expanded or contracted by the addition or subtraction of heat, it is obvious that the fluid would sink or rise in the tube, and thus mark the degree of heat. The Florentine academicians had the merit of considerably improving the apparatus of Santorio, by substituting alcohol for air, and by confining it in a tube nearly similar to the one now in use. Halley is said to have been the first who employed mercury, and Newton made the very important improvement of forming a regular scale, by which the observations might be recorded and compared together. It is, however, to Hooke that we are indebted for what may be regarded as a still greater improvement, viz. the formation of fixed points in the scale, by which, at all times and in all cases, thermometrical observations might be compared together, and be, as it were, all referred to one invariable standard. He perceived that water became solid always at the same temperature, and that, under the same atmospherical pressure, the fluid always becomes converted into vapour at the same degree of heat. Hence it follows, that if we immerse a tube containing mercury first into freezing, and afterwards into boiling water, we obtain two stationary and invariable degrees or points in the scale, which will bear the same relation to the temperature of other bodies, whatever be the size of the instrument, or under whatever circumstances the experiment is performed. Having ascertained these points, the numbers which are affixed to them, or the number of degrees into which we divide the interval between them, is entirely arbitrary, and comparatively unimportant.

The thermometric scale in general use in this country was formed by Fahrenheit, in which the cypher or zero is supposed to be indicated by a mixture of common salt and pounded ice. The freezing point of water is fixed at 32°, and the boiling point at 212°, so that the interval between the freezing and boiling of water comprehends 180°. In France, before the Revolution, the thermometer of Reaumur was generally employed. Here the freezing of water is the zero, or the commencement of the scale, and boiling water is assumed as the 80th degree. Since the Revolution, the centigrade scale is employed, which had been previously adopted by Celsius, a Swedish philosopher. Here freezing water is marked 0°, and boiling water 100°. Perhaps none of them are without considerable objections. Fahrenheit and Reaumur's scale are completely arbitrary; while the centigrade has its degrees too large for many purposes, and it has also the defect of beginning too high, so that we have very frequent occasion to employ the terms + and —, which may lead to confusion. Of the three, that of Fahrenheit is certainly the best; both because it is, in a great measure, free from this last objection, and because the degrees are not too large. Nor is it of much consequence that the commencement and termination are so entirely arbitrary; for when we are once accustomed to it, the mind refers to it as a term of comparison, without ever considering the reason for fixing upon the numbers that are employed.

The fluids employed in the formation of thermometers are either mercury or alcohol. Where we wish to ascertain very low temperatures, the latter is preferable, because it cannot be frozen but by the most intense cold, see Cold, whereas mercury becomes solid at — 39°. But for every other purpose, mercury has a decided advantage. Its expansions from the same additions of heat are more uniform; it is also more sensible to slight variations of temperature; and its boiling point is so elevated, that it possesses a range in the upper part of the scale, which is applicable to most practical purposes. Except, therefore, for measuring very low temperatures, mercury is now always preferred. See Thermometer.

A great deal of attention has been paid to the question, whether mercury, or any other fluid used for thermometrical instruments, was an exact measure of the additions of heat? whether the expansion was the same, by adding a certain quantity of heat at the lower as in the higher part of the scale? The experiments of Deluc on this point are regarded as the most correct. He observed the height to which the mercury rose in the tube, by immersing it in two equal portions of water, at temperatures considerably different from each other; then he mixed the two portions of fluid together, and examined whether the thermometer indicated the mean between the two. The result of Deluc's investigation was, that no fluid is an exact measure of temperature; but that, in all cases, the augmentation of bulk is in a greater ratio than the actual addition of heat. Mercury appeared to be the most uniform; but even in this fluid, the temperature of a mixture of two portions, one at the freezing, and the other at the boiling point, was 2½° less than the mean. The real temperature in this case is 122°, but, according to the common graduation, the thermometer stands at 124½°, (*Recherches*, t. i. p 311.) Hence, in order to obtain a precise measure of the increments of heat, we ought to have a thermometer so graduated as to allow for this deviation; and although we are not aware that any instruments have been constructed upon this principle, yet tables have been calculated by which a proper scale might be very easily formed.

The thermometer, however, in its most improved form, is only applicable to a range of temperature below that at which mercury boils; and although this includes most cases that usually fall under our observation, yet we have not unfrequently occasion to measure much higher degrees of heat. Newton attempted to accomplish this point, without any apparatus directly adapted to the purpose, by a species of computation. He ascertained the rate at which bodies cool, compared to the heat of the surrounding medium, at temperatures within the reach of the thermometer, and he then extended the same ratio to the higher degrees of heat. By this very ingenious method he discovered the temperature of red hot iron, and the melting point of many of the metals, with a considerable degree of precision. Since his time, different instruments, called *pyrometers*, have been invented, of which the most valuable, and that which has come into the most general use, was invented by Wedgewood. In the course of his experiments on the manufacture of earthen ware, he perceived that the different kinds of earths, called *clays*, into the composition of which a large quantity of alumine enters, had the remarkable property of contracting by exposure to a great heat, and likewise that this contraction was in proportion to the degree of heat employed. When the clay has once contracted, its bulk remains permanently diminished, so that by applying it to a gauge, previously graduated for the purpose, we can ascertain to what degree of heat the piece of clay in question has been exposed. The gauge by which the contraction of the clay is ascertained, consists of two straight pieces of brass, fixed on a brass plate in such a manner that they are nearer together at one end than at the other; and thus the more the clay has been contracted, the farther will it slip between the brass bars. Wedgewood then proceeded to examine the relation between his pyrometer and the common mercurial thermometer, and he determined that the 0° of his scale was equivalent to the 1077° of Fahrenheit's, were it so far extended. The degrees, the size of which was arbitrary, were each of them equal to 130° of Fahrenheit's; and the highest temperature which he actually measured was 160° of his pyrometer, corresponding to above 21 800° of Fahrenheit, which was found to be the temperature of a particular air furnace which he employed in his experiments: (*Phil. Trans.* 1782, p. 305, *et seq.*) This pyrometer has generally been regarded as a very valuable addition to our philosophical apparatus; but there is one circumstance which unfortunately much impairs its use—the difficulty of procuring the same kind of clay on which Wedgewood operated for the test pieces, as the mass which he originally employed is exhausted; and it does not appear certain, whether the imitation of it that has been since prepared, is possessed of precisely the same physical properties. See Chemistry,

Several other pyrometers have been invented, depending upon different principles, and possessing different degrees of accuracy. Muschenbroek, Ferguson, Ellicot, and Smeaton, have all exercised their ingenuity upon this point; but the only apparatus which we shall farther notice is that of Guyton. In this instrument along rod of platina is fixed in an horizontal groove, formed in a mass of clay that had been hardened by exposure to a strong heat; one end of the rod extends beyond the groove, and presses against another rod of platina, which acts as a lever; its longer arm being extended, so as to form an index, which moves upon a graduated arc. As the rod is more or less expanded by the heat, the index is carried along the scale, and serves to point out very minute variations in the bulk of the metal: (*Ann. Chim.* tom. xlvi. p. 276.) We are not certain whether this instrument has ever been employed in England; but it appears to possess many advantages as an accurate measure of high temperatures. See Pyrometer.

3. We now arrive at the *third* of the effects of heat, the change which it produces in the state of bodies, converting, according to circumstances, a solid into a liquid, or a liquid into an aeriform fluid. The effect of caloric, which we last described, consists in introducing a portion of heat between the particles of bodies, by which they are, to a certain extent, separated from each other, so as to experience an increase of bulk, without having their cohesion materially impaired. If, however, the addition of heat be continued beyond a certain limit, the particles are removed still farther from each other, until at length they are so far separated, as to lose their cohesive power, and to become easily movable among themselves in all directions. By this change of form, the substance in question undergoes a complete alteration in its physical properties, and not unfrequently in its chemical action upon other bodies. The effect is produced by destroying the balance between the expansive power of heat, and the force of attraction: the former tending to remove the particles of bodies to a distance from each other, the latter to retain them in close contact. But although the attractive force is conceived to be very much weakened in bodies when they assume the fluid state, it is not entirely destroyed, but is still exerted with considerable energy.

It is also to be remarked, that after a solid has received an addition of heat, so as to convert it into a fluid, a still farther quantity of heat may be given to it, which has the simple effect of expansion. If, however, we continue to increase the quantity of heat after the expansion has advanced to a certain length, the body again assumes a new form, and becomes a gas; and it now, as before, after this third change, by adding still more heat, suffers merely an expansion in its volume. But the expansion in these three cases, as has been already observed, differs considerably in its degree, being small in the first instance, greater in the second and much more so in the last. This peculiar quality of assuming the different states of solidity, liquidity, and elastic fluidity, may be considered as a property common to all kinds of matter; for it would appear, that if we had the power of producing, at pleasure, temperatures sufficiently high and sufficiently low, every substance that usually appears under the solid form might be vaporized, and every substance that usually appears as a vapour might be rendered solid. When we speak, therefore, of any body being naturally in the solid, or naturally in the liquid state, we mean no more than that, under the ordinary temperature of the atmosphere, or under the circumstances in which it commonly presents itself to our notice, it is solid or fluid.

There is, indeed, another obstacle to altering the state of bodies, besides the difficulty of procuring very high or very low temperatures, that by a great addition or subtraction of heat, their chemical constitution is affected, and they are either decomposed, or are disposed to enter into new combinations. Organised substances in general, both of animal and vegetable origin, when subjected to high temperatures, are converted into their ultimate elements; and, on the contrary, in some cases, a great reduction of temperature causes the constituent parts of certain bodies to separate from each other, before they are brought into the solid form. These, however, are to be regarded rather as incidental circumstances, interfering with particular operations, than as any fundamental exceptions to the general law that has been laid down. It would appear from the experiments of Sir James Hall, that many of these apparent exceptions may be brought under the general rule, merely by employing strong pressure or other mechanical means. Thus it has been supposed impossible to melt the carbonate of lime, because at an elevated temperature the carbonic acid escaped in the form of gas; but when the substance was subjected to strong compression, so as to prevent this escape of gas, the fusion was easily accomplished.

The suddenness of the change which occurs when the body receives so much heat as to convert it into the liquid state, shews that some other circumstance takes place besides the mere addition of caloric. And the same remark applies to vaporization; for here again no indication of the change of state can be observed, until the actual change occurs in its full extent. This point we shall soon consider more at length; but, in the mean time, before we quit the subject of the change of bodies from the solid to the liquid form, we must offer a few observations upon some phenomena that occur when we reverse the operation, and convert them from the liquid to the solid state. All bodies that undergo this change, without having their chemical constitution materially altered, have a fixed point at which they are said to freeze, congeal, or become solid; and except under certain circumstances, this point is invariably the same. This is so much the case with respect to water, that the freezing point of this fluid has been employed as one of the fixed degrees which regulate the graduation of the whole scale.

It is, however, possible, by certain management, to cool water several degrees below its freezing point, without rendering it solid; according to the experiments of Mr Dalton, as low as 5°, or 27° below the usual point of congelation. In order to succeed in giving water this unusual degree of cold, without converting it into ice, it is necessary that it be kept in a state of the most complete rest: for the least agitation either prevents it from falling lower than 32°, or if it be brought down below this point, it instantly begins to freeze, and the fluid part rises to 32°. Black found that by carefully boiling the water, so as to expel from it all the air which is generally dissolved in it, it was less easy to reduce the temperature below the ordinary degree; and Blagden discovered, that when water is thus artificially cooled, no circumstance had more effect in producing its sudden congelation, than introducing into it a small particle of ice. Hence, when the freezing of water has once commenced, it proceeds with so much rapidity in these experiments; and it may perhaps also in some measure, account for the effect which water confined in close vessels has in bursting the vessel when it freezes. In these cases the fluid may probably descend some degrees below the usual freezing point, before the congelation commences; a slight agitation, or other incidental circumstance, then causes the freezing to commence, and the first spiculæ of ice that are formed tend to convert the remaining part of the water into the solid state so rapidly, as to produce a greater expansion, than if the particles had arranged themselves more quietly in the crystalline form.

The effect of a continued addition of heat to a liquid is, as we have remarked above, to convert the liquid into the state of vapour. This, like the former, is a sudden change, and, like it, is attended with a complete alteration in the physical properties of the substance so changed. A certain portion of caloric added to a body, insinuates itself among the particles, and places them so far from each other, as to diminish the attraction which unites them into the solid form, without, however, entirely destroying their aggregation; while a larger portion removes them to a still greater distance, and seems as if it entirely placed them beyond the reach of their mutual attraction. The most obvious property of the body, when in this vaporized state, is its power of expanding itself in an indefinite degree, until its particles be brought nearer together by an external compressing force. If this external force be removed, it quickly regains its former dimensions; and hence we regard it as a body possessed of a perfect degree of elasticity. It is upon the elastic power which different substances possess, when they are converted by heat into the gaseous or aeriform state, that many of the most important operations, both in art and nature, are brought about. The force which different bodies exercise when they are reduced into the gaseous state, and are at the same time subjected to strong pressure, is almost inconceivable; it is, in short, unlimited in its extent, and may be so managed as to produce any assignable degree of effect. Notwithstanding, however, the expansive power which bodies exercise during their conversion from the fluid to the gaseous form; yet when they are finally brought into this state, they are compressible. Thus, although the conversion of water into an aeriform fluid is capable of generating an almost immense degree of mechanical power, in consequence of the greater space which it then occupies, a power of which we take advantage in the steam engine, yet the vapour, when once produced, may be easily compressed into a less bulk, by the weight of a comparatively small quantity of mercury. Farther increments of heat, when added to the gas, only serve to produce a corresponding increase of its bulk; and this increase, as we have already remarked, is equable for the same quantity of heat, and is likewise similar in all the different gaseous bodies.

The point of vaporization, like that of solidification, differs for almost every kind of liquid. There are some bodies that always appear in the state of gas when not combined with other substances, and no degree of cold which has yet been applied to them has been able to deprive them of their elastic fluidity. Yet from analogy we conclude, that these bodies have nothing in their nature essentially different from those which we observe to assume either the liquid or the gaseous state, according to the temperature in which they are placed; and we conceive, that, had we the power of employing a degree of cold sufficiently intense, they might be rendered liquid, or even solid. Ether has the lowest and mercury the highest vapour points of any liquids with which we are acquainted. If we were always immersed in a temperature above that at which ether boils, we should never see it in a fluid state; and if we had not been able to produce a temperature above 670°, at which mercury boils, we should have had no conception of this substance being reducible into the state of a vapour. The terms *fixed* and *volatile*, like *solid* and *liquid*, are therefore to be regarded as merely relative, and as not indicating the absolute quality of the bodies, but pointing out the forms under which they usually present themselves to our notice. But although we regard this as the most correct view of the subject, yet many chemists of eminence have supposed that there is some essential or radical difference between the two kinds of aeriform fluids, and have called them by different names; to those that are easily reduced to the liquid state, the term *vapour* has been exclusively applied, while the others have been called *gases*, or permanently elastic fluids. The discussion of this question belongs more to chemistry, than to the immediate subject of this article; but we shall farther remark concerning it, that when, by the effect of chemical affinity, these gases are reduced to the liquid or solid form, heat is extricated; thus proving that it entered into their constitution, and was necessary to their existence.

An important circumstance connected with the conversion of liquids into the state of elastic fluidity, is, that it is influenced by the degree of pressure to which the liquid is subjected. External pressure thus counteracts the repulsive power of heat, and as it were keeps the particles in a state of forcible approximation. It follows, from this order of things, that if we remove from the surface of a liquid the whole or a part of the weight of the atmosphere, by placing it under the receiver of an air-pump, or by ascending a high mountain, it boils at a lower temperature than under ordinary circumstances. Thus water, which boils at 212° when the barometer stands at 30 inches, boils at about 70° *in vacuo*; and on the top of Mount Blanc, it was found by Saussure to boil at about 187°. As the temperature at which different species of elastic fluids are formed depends so much upon the pressure which is applied to them; so, after the gaseous state has been assumed, the elastic force of the vapour varies according to the degree of pressure under which it exists. Mr Dalton has made this the subject of an extensive range of experiments, in which he determines the height of the the mercurial column which the vapour of water will support at different temperatures. Thus if the vapour of water be taken at the freezing and boiling points, and at 122°, which is intermediate between them, he found that the column of mercury supported in these three cases was equal to 0.2, 3.5, and 30 inches respectively. By making a few experiments, and observing the ratio which the numbers in these cases bore to each other, he constructed a table containing every degree of heat, from 0° on Fahrenheit's scale to 325°; (*Manch. Mem.* vol. v. p. 559.) Experiments of a similar kind have been performed in France by M. Bettancour. As the boiling point of liquids is lowered or raised, according as the atmospherical pressure upon them is diminished or increased, it has been found, that if the pressure be augmented in a very great degree, as is the case when water is inclosed in Papin's digester, it is capable of receiving a much higher temperature than what it can maintain under other circumstances. Water has, in this way, been heated 200° or 300° beyond its usual boiling point; and it has then acquired the power of dissolving many substances, over which it has no action in its ordinary state.

It is upon the property which liquids possess, of being convertible into the gaseous state, that the processes of evaporation and distillation depend. The first of these is performed, when our object is to separate the more volatile parts of a compound, for the purpose of procuring those that are less so; and the second, on the contrary, is done in order to procure the volatile part itself. A minute account of these operations belongs more to chemistry, and to the various branches of chemical manufactures, than to the general view which we are taking of the effects of heat. (See DISTILLATION and EVAPORATION.) In both cases, the separation is effected by the combination of heat with the liquid; in the one, it is sometimes produced by the heat which naturally exists in the atmosphere, aided by a current of air, continually presenting a new stratum to be acted upon; and at other times a quantity of heat is thrown into the substance by the combustion of some kind of fuel. It is, however, necessary, in either case, that a large surface should be exposed to the atmosphere, for the purpose of carrying off the vapour as rapidly as it is produced; for it appears that it is principally at the surface that it is generated. In the process of distillation, artificial heat is always employed, and commonly in a greater degree than where the object is merely to produce evaporation. Here the liquid is confined in close vessels; and the operation depends upon a portion of it, which is nearest the source of heat, becoming converted into vapour, and passing up through the other parts of the fluid in the form of bubbles, constituting what is styled *ebullition*.

We have already remarked, that when a solid is converted into a liquid, or a liquid into an elastic fluid, the conversion is brought about suddenly. The substance in question, before it changes its state, continues to receive heat, is expanded in a certain degree, and has its temperature raised; but if an additional quantity of heat be still given to it, the expansion no longer goes on in the same manner, and the temperature is no longer elevated, but it assumes a new form, becoming, according to circumstances, either a liquid or a vapour. It was formerly supposed, that this change did not depend upon any peculiar or specific action, but that the mere addition of a certain small portion of heat was adequate to effect it. Dr Black, however, perceived the insufficiency of the opinion usually entertained upon the subject, and was induced to investigate it with great assiduity; the result of which was, the establishment of his celebrated theory of latent heat. The fundamental position of this theory is, that when a solid is converted into a liquid, or a liquid into a gas, a much greater quantity of heat is absorbed by it than is perceptible by the sensations, or the thermometer, the effect of which is to unite with the particles of the body, and thus to alter its form. When, on the contrary, the vapour is reduced to the state of a liquid, or a liquid to that of a solid, heat is disengaged from it, without the substance in question indicating any diminution of temperature, either to the sensations, or to the thermometer. This phenomenon is considered to be the reverse of the former; here the heat that escapes is not supposed to have affected the body in the way that free caloric acts, but simply to have maintained it in the state of elastic fluidity, or of liquidity.

We are hence led to regard heat as existing in two states that are essentially different from each other: the one producing temperature and expansion, and of course capable of being measured by the thermometer; the other not manifesting these properties, but uniting itself to bodies, and changing their form. The former we call free or uncombined heat; the latter latent or combined heat. As we are in the habit of conceiving temperature and expansion* to be the most certain indications of the presence of heat, it required a train of minute experiments to establish a position, which appeared, at first view, so much at variance with our ordinary conceptions, as that heat could be communicated to bodies without producing these effects. The following facts may be considered as the ground-work of Black's doctrine. Let a mass of pounded ice, cooled several degrees below the freezing point, be exposed to the heat of a furnace, so that it may receive equal quantities of caloric in equal intervals of time. The ice, as it receives the heat, becomes warmer at each successive interval, until the whole acquires the temperature of 32°; but now, although the heat still remains applied as before, the ice acquires no additional warmth; it still indicates 32° to the thermometer, but it is observed gradually to dissolve. No increase of temperature takes place until the whole is rendered fluid, and then it again begins to grow warmer, and, as before, acquires successive increments of heat, until it arrives at the 212th degree. Here, again, the process ceases; and whatever quantity of heat be sent into the fluid, its temperature remains unchanged; but now the fluid is observed gradually to assume the state of vapour, until the whole of it is converted into the aeriform state. Now there is every reason to conclude, that in this case the ice and water continue to receive equal quantities of heat for the whole period; yet during some part of the process, the thermometer remains stationary. At this very time, however, the change of form occurs; and therefore it is natural to conclude, that it is connected with the absorption of a portion of heat, which, in consequence of its not producing either temperature or expansion, has obtained the name of *latent*. The legitimate inference is, that a certain quantity of caloric, which would otherwise have been employed in producing temperature and expansion, is necessary in the one case for melting the ice, and in the other for vaporizing the water.

What we have now stated may be regarded as the foundation of the celebrated theory of latent heat; which has been universally received, as affording a satisfactory explanation of some of the most interesting phenomena that occur in the system of nature. A number of very important consequences were immediately deduced from it, of which we may enumerate the two following, as those the most deserving our attention:

1. When solids become liquid, and liquids become elastic fluids, a quantity of heat, previously latent, becomes sensible, and may be now measured by the thermometer, although before it was not capable of affecting this instrument. On the contrary, when vapours are converted into liquids, or liquids into solids, a portion of heat, which was previously in the uncombined state, is now absorbed or rendered latent. In the former process, therefore, warmth is produced; in the latter, cold is generated.

2. Substances which are at the same temperature actually contain different quantities of heat. Ice, just before liquefaction, and the water which is formed, are both at the temperature of 32°, and steam is no hotter than the boiling water from which it is produced; so that the water and the steam both contain a large quantity of heat, in the combined or latent state, which they have absorbed in order to cause the fusion of the one, and the vaporization of the other. This property in bodies, of indicating the same temperature when they contain different quantities of heat, is denominated their capacity for heat; while the quantity of heat which they require to bring them to the same temperature is called their specific heat, in opposition to the real quantity, which is styled their absolute heat.

It would carry us far beyond our prescribed limits, were we to give an account of all the experiments which were performed by Black, for the purpose of establishing his theory, and of repelling the objections against it. They consisted, in the first place, in comparing the effect produced by the same quantity of heat upon bodies which possessed different capacities, as ice and water. When the same weight of ice and water, both at the temperature of 32°, were suspended in an atmosphere of 47°, the water rose to 39° in 30 minutes, while the ice required ten hours to become liquid, and to acquire the same temperature. The ice, therefore, was 21 times as long as the water in acquiring the same degree of warmth, and we may conclude that it would absorb 21 times as much caloric. While the number of degrees gained by the water was no more than seven, the number that entered the ice would be 147°; but of these only seven were employed in warming the substance, the rest were expended in melting it. Hence we should say, that when ice is converted into water, 140° degrees of caloric are rendered latent. The same general conclusion was obtained by a different process. When two equal portions of water, at unequal temperatures, are mixed together, the mixture indicates the mean temperature of the two portions; thus a pound of water at 32°, and a pound at 172°, produce a mixture which indicates 102°; but if we mix a pound of ice at 32°, with a pound of water at 172°, the ice is melted, but the temperature of the fluid is not raised. Hence the 140° of heat are all employed in thawing the ice, and thus become latent.

The absorption of heat that takes place when solids are melted, or liquids evaporated, and the discharge of heat that occurs in the reverse operations, are often employed in different processes, for the purpose of cooling or warming bodies. The effect of evaporation in generating cold is well known, both as it affects the sensations, and as it actually reduces the temperature of substances. In hot climates, fluids and various articles of diet are preserved at a temperature considerably below that of the atmosphere, by placing them in vessels, from the surface of which evaporation is continually going forwards; and by the proper management of this process, even ice is formed in considerable quantity, for the purposes of domestic economy, at a temperature some degrees above the freezing point. By means of the evaporation of ether, water is easily frozen at the medium temperature of our climate, and indeed a degree of cold may be generated far below that of the freezing point. A still greater diminution of temperature is produced by a solution of certain salts;† a circumstance which depends partly upon the heat that is rendered latent by the conversion of a solid into a liquid, and partly by the mixture possessing a greater capacity for heat than the ingredients in their separate state. To these two circumstances, the change of state which bodies experience, and the change in their capacity, as depending either upon this alteration in their state, or upon the new combinations into which they enter, we ascribe the increase of temperature which occurs in a variety of chemical operations, where caloric is not introduced from any external source. The heat, which is excited by combustion, is to be attributed

* It will be seen, in another part of this article, that expansions and contractions are produced by heat in glass and other substances, where it *does not exist in a sensible state*. See page 286.—Ed.

† See Walker's experiments on freezing mixtures, *Phil. Trans.* 1801, p. 120; and our article Cold, vol. vi. p. 733, 734.

to the latter cause, the change of capacity in the substances; the products of combustion, particularly the carbonic acid, being supposed to possess a less capacity than the carbon and oxygen before their combination.

The cases in which the conversion of a body from the liquid to the solid form actually produces an increase of temperature, are not very numerous; but there are not unfrequent instances in which the rate of cooling is obviously retarded by this process. And in no operation is this more remarkable than in the natural freezing of water. When water is exposed to the influence of external cold, its temperature sinks in proportion as the heat is removed from it, until it arrives at 32°; the refrigeration is then suspended, but the water begins to become solid, and the temperature remains stationary, until the freezing is completed; then the cooling recommences, and is continued until the ice arrives at the temperature of the surrounding medium. The freezing of water, however, under particular circumstances, affords an example of the actual evolution of heat. This takes place in that case which has been described above, where water has been cooled below 32° without becoming solid; if it be then agitated, or a small spicula of ice be introduced into it, the congelation takes place with great rapidity, and the portion of water which still remains fluid instantly rises to 32°. An experiment of an analogous kind may be performed on the crystallization of salts. By proper management, a warm saturated solution of the sulphate of soda may be cooled for several degrees, without any of it beginning to crystallize; if the vessel be then slightly shaken, the process suddenly commences, and a large part of the salt immediately becomes solid, in consequence of which the temperature will be very sensibly raised. The general law, both in this and the reverse operation, is, that the most powerful effect, either of heating or cooling, takes place when the process is performed with the most rapidity, when the substance that has its state or its capacity changed, has its equilibrium with the neighbouring bodies restored in a short space of time, and therefore most perceptibly affects their temperature.

The same kind of experiments which Black performed, to establish the absorption of heat, when a solid is converted into a liquid, he afterwards made on the conversion of a liquid into an elastic fluid. He also attempted to ascertain the exact quantity of heat which is rendered latent in this operation, in which he was essentially aided by Mr Watt; and the result of their inquiry was, that when water assumes the state of vapour, it absorbs 950° of caloric.* This number he obtained in two ways: 1st, By comparing the heat necessary to raise the temperature of a certain portion of water to the boiling point, with the effect produced by an equal addition of heat in afterwards evaporating the water; and, 2dly, By finding what quantity of caloric was extricated, when steam is reconverted into water by condensation. We have already mentioned, that when water is strongly compressed, as by being inclosed in Papin's digester, its temperature may be raised far above the boiling point, without its assuming the aeriform state. In this case its tendency to evaporation is mechanically prevented, by the particles not being allowed to separate from each other; and therefore, as it cannot alter its form, its capacity remains the same, and its caloric all continues to be in the uncombined state. But if the pressure be suddenly removed from the water, its particles now being at liberty to expand themselves, they unite to a portion of the heat, instantly assume the elastic state, and the remainder of the fluid sinks to 212°.

We have already explained, in a general way, the meaning of the term *capacity for heat*, and the difference between the absolute and the specific heat of bodies; but we must illustrate the subject with a little more minuteness. As a foundation for our reasoning, it may be assumed, that when equal quantities of the same substance, but at different temperatures, are mixed together, the temperature of the mixture indicates that of the arithmetical mean of the two ingredients. This, however, only applies to bodies of the same kind; for when different substances are employed, it is impossible to predict what will be the temperature of the mixture. Thus if a pound of water and a pound of mercury be mixed at different temperatures, the result will not be the mean temperature; but it will be found that the mercury loses 28°, while the water gains only 1°. Water is therefore said to have 28 times the capacity for heat that mercury has, because it requires 28 times as much to produce the same change of temperature; or, to use a different, and perhaps a more correct phraseology, we say that the specific caloric of water is to that of mercury as 28 to 1. Proceeding upon this principle, and taking water as a standard of comparison, numerous experiments have been made on the specific heat of various substances, particularly by Crawford, Irvine, and Wilcke.

The method employed by Crawford was to mix together, at the same temperature, the substance to be examined and water, the specific heat of which is considered as one, being that with which all the rest are compared. He then multiplied the weight of each body by the number of degrees between its original temperature and the common temperature obtained by their mixture, and the capacities will be inversely as the products. (*On Animal Heat* 2d edit. p 96, *et seq.*) It is generally more convenient to employ a definite weight of the substance to be examined, than to measure it by its volume; but when we examine the specific heat of equal volumes of different bodies, we find the same want of correspondence between the results, so as to prove that the capacity for heat is a property which bears no exact ratio to any other physical quality. In the performance of these experiments, much dexterity is requisite, in order to ensure even a tolerable degree of accuracy; and after all, the results of different trials, made upon the same substance, will not always be found to correspond, yet there seems to be no doubt of the correctness of the principle, and, in many cases, we may conceive that we arrive at a near approximation to the truth. See CHEMISTRY.

Mr Leslie has proposed another method of ascertaining the specific heat of bodies; it consists in comparing the time which they occupy in cooling with the cooling of water placed under precisely the same circumstances. The apparatus which he employed was a thin glass globe, furnished with a neck capable of receiving a delicate thermometer. He observed the time necessary for water to cool a certain number of degrees in this globe suspended in the air, then he fills the instrument with another fluid, the specific heat of which he wished to examine, and heats it to the same degree, and suspends it in air of the same temperature, and observes the time necessary for it to cool the same number of degrees. It is found, that, under the same circumstances, water cooled in 70 minutes, while oil required 32 minutes only; therefore, by estimating water at unity, as the standard of comparison, the specific heat of oil will be .46, if we estimate it by bulk, or .5, if we estimate it by weight. *Inquiry*, p. 170.

The great difficulty there is in executing experiments

* The late Mr Southern found, from numerous experiments, that the latent heat of steam at the temperatures 229°, 270°, and 295°, is 942°, 942°, and 950°. See Mr Watt's Annotations on Dr Robison's article STEAM, in Robison's *System of Mechanical Philosophy*, vol. ii. p. 166.—ED.

like those of Crawford's, where the substances are mixed together, and the specific heat calculated from the temperature of the mixture, induced Lavoisier and Laplace to attempt to solve the problem by a new method. They proceeded upon the fact, that when ice is melted, it must always absorb the same quantity of heat, and therefore that the caloric which is disengaged from any body, by a change in its form, or from the union of two or more bodies, may be accurately measured, by placing the substance in such a situation as that all the heat must necessarily pass into a stratum of ice; and from the amount of water produced by the melting of the ice, the quantity of heat given out may be estimated. The apparatus which they invented to accomplish this purpose, they called a *calorimeter*; it consists of three vessels inclosed one within another, so as to leave a cavity between each of them. The substance which is to be the subject of experiment is placed in the innermost vessel; the second is filled with pounded ice, and is provided with a tube at the bottom, through which all the water that is formed is conducted into a suitable vessel, where it may be collected and measured. The outermost space is also filled with ice, in order to preserve the interior of the apparatus at the proper temperature: (*Mem. Acad. Scien.* 1780, p. 368.) This instrument is constructed upon scientific principles, and seems both simple and ingenious; yet we are informed that there are some circumstances which interfere with its practical utility, and we believe it has never been employed except by the inventors. See Wedgewood in *Phil. Trans.* 1784, p. 371, *et seq.*; and CHEMISTRY.

The capacity of gaseous bodies for heat, like that of liquids and solids, varies according to the nature of the individual gas; but the determination of their respective capacities requires a delicacy of experiment, proportionate to the difficulty of operating upon substances of so subtle a nature. It has, however, been attempted by Crawford, and prosecuted by him with much perseverance and ingenuity, and made the foundation of some very important doctrines, both in chemistry and physiology. It must indeed be confessed, that the extreme nicety of the process necessarily makes the conclusions liable to much uncertainty; yet the general results have been, for the most part, acquiesced in, although they have been considerably altered since they were originally brought forward. Of late, however, they have been controverted by MM. Delaroche and Berard, who have published a very elaborate set of experiments, which they performed upon the specific heat of the gases, in which they employed an apparatus of a new construction. It is in fact a calorimeter; but instead of measuring the heat which is extricated by the quantity of ice which it will melt, they endeavour to ascertain what quantity of heat the gas will impart to a mass of water; and for this purpose a current of the gas is sent along a serpentine tube, which traverses a cylinder of water. The instrument appears to us to be very complicated, and to require a great share of manual dexterity in the operator, a circumstance which we always consider as very objectionable: (*Ann. Chim.* lxxxv. 72.) But although their results differ considerably from those of Crawford, they agree with him in the general principle, that the specific heat of the gases is different from each other, whether we attend to their volumes or their weights, and that there is no relation between the specific gravity of the gases and their specific heat. See Description of Plates at the end of the Volume.

Besides the difference in their capacities for heat, which gases possess in consequence of a difference in their nature, this property is also much affected by the degree of compression which they experience, or is in proportion to their density. It is consequently observed, both in experiments performed for the purpose, and in many natural processes, that the sudden condensation of air generates heat; and, on the contrary, that sudden dilation produces cold. Whenever an expansion of air takes place, either from the removal of pressure, or from any other cause, the particles are more widely separated from each other, in consequence of their elasticity being now at liberty to exert itself; and it would appear, that a quantity of caloric necessarily rushes in to supply the vacuity. This, although merely a mechanical view of the subject, appears to be rendered probable by the fact, that the emission and absorption of heat are respectively produced by causes, which can only be supposed to act by bringing the particles of the gas nearer together, or removing them farther asunder. If a thermometer be placed in the receiver of an air pump, and the air be quickly exhausted, the mercury will sink several degrees; and if, on the contrary, air be rapidly condensed by the appropriate apparatus, the mercury is considerably elevated. (Dalton in *Manch. Mem.* vol. v. p. 515.) The heat which is excited by condensing the atmosphere in the barrel of an air-gun is well known; and by employing it in the most advantageous manner, sufficient heat may be extricated to set fire to a piece of tinder. If a part of the apparatus be composed of glass, a flash of light is perceptible, when the stroke of the piston is made with great force and rapidity. The effect of the rarefaction of air in promoting the absorption of heat is well illustrated in Professor Leslie's new method of forming ice. (See our article COLD, for a full account of this process.) In this process, water is placed in a shallow dish over a vessel containing sulphuric acid; the whole being enclosed in the receiver of an air-pump, and a vacuum produced. As the exhaustion proceeds, the quantity of heat abstracted from the water, in order to supply the evaporation, quickly converts the whole into ice. The sulphuric acid, in this case, promotes the effect, by its attraction for the aqueous vapour, which it absorbs as fast as it is generated. A still more striking effect of evaporation has been exhibited by Dr Marcet. He enclosed a quantity of mercury in a bulb of thin glass; this was wrapped up in cotton, which was soaked in the very evaporable fluid, the sulphuret of carbon; the apparatus was then placed under the receiver of an air-pump, and the exhaustion produced, when the mercury was completely frozen: (*Phil. Trans.* 1813, 252.) The ingenious instrument invented by Dr Wollaston, which he called the *cryophorus*, acts upon the same principle. It consists of a glass tube of some length, each extremity of which terminates in a globe about one inch in diameter, and bent at a right angle to the tube; one of the globes is half filled with water, while all the remainder of the apparatus is carefully exhausted of air. If the empty globe be plunged into a freezing mixture, the aqueous vapour with which it is filled is so rapidly condensed, that a portion of the water in the second globe is immediately frozen. *Phil. Trans.* 1813, 71.

The condensible vapours, such as the steam of water, are more expansible than the permanent gases; and it has therefore been conceived, that they will acquire a greater degree of heat when they are permitted to enlarge themselves, by removing from them the pressure of the atmosphere. Mr Watt proved that this was the case, in some experiments which he performed on the distillation of fluids *in vacuo*; a process which has been recommended as an economical project, in consequence of the smaller quantity of caloric which is necessary, under these circumstances, to convert the liquid into a vapour. But this he found was counterbalanced by the greater capacity for heat of the vapour, when in its most rarefied state. By taking off a considerable part of the atmospherical pressure, water could be distilled at a temperature of 100°; but its latent heat then appeared to be 1048°, instead of 840°, the latent heat of steam generated in the atmosphere. With the most perfect vacuum that could be formed, water may be distilled at 78°; but then the latent heat is still farther increased, so as to be about 1300°. Mr Watt estimated, that when water is converted into a vapour, under the ordinary pressure of the atmosphere, it is expanded into about 1800 times its former bulk. *Phil. Trans.* 1784, 335; and Black's *Lectures*, vol. i. p. 190.

Dr Crawford, from his experiments on the specific heat of bodies, was led to form the conclusion, that while their state remains unchanged, their specific heat continues to bear the same relation to their absolute heat. Taking water as the standard of comparison, if we can discover what proportion the specific heat of this fluid bears to mercury at the usual temperature of the atmosphere, we may suppose that the same proportion will exist at all temperatures. Upon this principle was founded the proposal of Irvine, for ascertaining the real zero, or that point of the thermometric scale at which, if it be supposed to be sufficiently extended, bodies would be deprived of the whole of their heat. Thus it had been found by experiment, that the capacity of ice is to that of water as 9 to 10, and the actual quantity of latent heat in water was estimated at 140°; therefore ten times 140°, or 1400° below the freezing point, was supposed to be the temperature at which water is absolutely deprived of all heat (Nicholson's *Chemistry*, p. 16; Crawford *On An. Heat*, p. 435.) The proposal of Dr Irvine is certainly ingenious; but we conceive the problem to be one, which we are still very far from being able to solve with any degree of accuracy. Indeed, the fundamental positions, upon which the whole hypothesis rests, are themselves very dubious, and the experiments which have been performed on the subject by different philosophers, have been attended with such very discordant results, as to show, that either the theory or practice must be extremely imperfect. Besides Irvine's, the principal experiments which were performed, are those of Crawford, Gadolin, Lavoisier in conjuction with Laplace, and Seguin. Of these, Gadolin's seem to have been executed with the greatest care and accuracy, and they approach the most nearly to those of Irvine. His method was to ascertain the capacity of common salt, and also of its solution in water, and then he observed the degree of cold which is produced during the solution. He afterwards examined the quantity of heat which was absorbed by the mutual action of common salt and snow, and the heat extricated by the mixture of sulphuric acid and water; and, by comparing these with the capacity of the bodies before their union, he endeavours, as before, to determine the proportion which their absolute bore to their specific heat. (Crawford *on An. Heat*, p. 457, *et seq.*) Lavoisier and Laplace employed the calorimeter, to measure the quantity of heat disengaged during the mixture of certain substances, comparing this with the capacity of the bodies separately; but it would appear, that their experiments were more liable to inaccuracy than those of Gadolin, and their results are completely at variance with each other: (*Mem. Acad. Scien.* 1780, p. 384, *et seq.*) Mr Dalton has attempted to discover the real zero, by a calculation depending upon his idea of the constitution of an aeriform fluid, and the relation which subsists between its basis, and the caloric which enters into its composition. Without attempting a detail of his hypothesis, we shall merely state his conclusion, that the absolute quantity of caloric in elastic fluids at different temperatures, is in the direct ratio of the cube roots of their bulk at the same temperature: (*Manch. Mem.* vol. v. p. 601.) How far this hypothesis may have any foundation in fact, we do not feel at present competent to decide; but it has been asserted, that experiments made upon this principle at different temperatures, and upon various substances, do not correspond to each other.

From the remarks that have been made, it will appear, that Dr Black's discovery of the existence of what he called latent heat, or of a difference in the capacity of bodies for heat, is a fact completely established by experiment, and one of the most important in the whole range of chemical science. Very different opinions, however, have been entertained respecting the manner of accounting for the fact, and especially the question has been warmly agitated, whether the absorption of heat when a solid is converted into a liquid, is to be regarded as the *cause* or the *effect* of this change of state. Dr Black conceived that it was the cause of the change; that the body in question, as, for example, a portion of ice, being exposed to the influence of caloric, this principle necessarily enters into it, becomes combined with its particles, and is not capable of producing any effect until it be again extricated by the liquid changing its form, or entering into some new combination. Dr Irvine adopted the contrary opinion, and regarded the absorption of heat as the consequence of a change of capacity which the ice undergoes when it is converted into water, which change of capacity necessarily causes it to absorb, and render latent a quantity of heat: (Black's *Lect.* vol. i. p. 194.) Dr Irvine's opinion seems to be supported by the fact, that there actually is this difference of capacity in the substance; but then it does not appear to assign any cause for the change of state which the body undergoes. If we adopt it, we are obliged to assume as a principle, that when the solid is so situated as to receive above a certain quantity of heat, its particles are suddenly forced to a considerable distance from each other, in consequence of something peculiar in its nature and constitution; and that when this separation has been effected, the capacity becomes increased, and the caloric of course absorbed. Dr Black conceived, that the caloric was united to the body by a power similar to chemical attraction; and if we adopt this opinion, it would follow, that at certain temperatures substances acquire different degrees of affinity for heat, and form with these quantities an intimate union, which renders it no longer cognizable by the ordinary means.

4. The last effect of heat, which yet remains for us to consider, is *ignition*. Ignition, or, as it is sometimes called, *incandescence*, is the property which some bodies possess, after being exposed to a high temperature, of becoming luminous, without any chemical change taking place in their composition. In this respect, it differs essentially from combustion, where the body extricates light, but where it is found to have experienced a complete change in its chemical nature. Combustion also differs from ignition in another particular, that, in the former process, the co-operation of the atmosphere, or some other external substance, is necessary; whereas the latter is capable of existing without the intervention of any other body. It has been conceived, that, by proper management, all solids, and even liquids, may be rendered luminous, or brought into the state of ignition; and Mr Wedgewood performed some experiments which lead to the conclusion, that they all undergo this change at the same temperature. Many philosophers have attempted to find out the exact degree at which ignition commences; and although their processes do not furnish precisely the same result, yet they correspond so far, as to render it probable, that it must be somewhere between the 800° or 1000° of Fahrenheit. Mr Wedgewood supposes,

that a body becomes just luminous in the dark at 947°; and that a full red heat, visible in open day-light, takes place at 1077°. According to the intensity of the temperature, the colour of the ignited body is altered. At first, it exhibits what has been called a cherry red; afterwards, the red acquires a yellowish tinge; and, lastly, all colour disappears, and we have only a brilliant white light: (*Phil. Trans.* 1784, p. 370.) It is generally supposed, that aeriform fluids are not capable of being ignited. A quantity of air, heated to such a degree that a piece of metal, when suspended in it, was rendered luminous, was itself quite invisible.

Respecting the cause of ignition, two opinions have prevailed; the first, that light is a modification of heat, and that, at a high temperature, the one becomes converted into the other; the second, that light actually exists as a component part of different bodies, and that, when the body is strongly heated, the light is propelled or disengaged from it. It is perhaps impossible to adduce any direct arguments in favour of either of these hypotheses; but the general relations of heat and light are in many respects so different from each other, that we are induced to adopt the opinion which supposes them to depend upon the agency of principles essentially dissimilar. This, however, we advance as a doctrine which must be confirmed or refuted by future observations and experiments.

## SECT. III.

### *Sources of Heat.*

After having described the properties and effects of heat, we must now give an account of the sources whence it is derived. Those that are usually enumerated are the following: the rays of the sun,—combustion,—a change in the capacity of bodies, and their chemical union,—the mechanical means of producing heat, as friction, percussion, and condensation,—and, lastly, the electric and galvanic discharge. The great source of heat to our world, and probably to the rest of our solar system, is the radiant caloric which is projected from the sun. When a sufficient number of rays are collected into one spot, either by a concave mirror, or by a convex lens, the most powerful heat is excited of which we have any conception; and we are capable of producing effects by it, which we cannot otherwise accomplish. The effect, however, is necessarily confined to a small spot; and therefore it can only be employed in refined operations of analysis, or for the purpose of delicate philosophical processes. It would appear, from an experiment of Rumford's, that the great heat excited in these cases, depends entirely upon the concentration of the rays, and not upon any change in their nature; because, when he directed a certain portion of the sun's rays against a substance adapted for absorbing them, the total amount of heat communicated to it was the same, whether the rays were received on the surface in a diffused state, or brought into a small focus.

The most important supply of heat which we have it in our power to produce at pleasure, is that which depends upon combustion. Nearly all the heat which we employ for domestic and manufacturing purposes, proceeds from the burning of fuel; an operation of a strictly chemical nature, in which a union takes place between the fuel and the oxygen of the atmosphere, the result of which is a combination of the combustible matter with the oxygen, and the extrication of a quantity of heat and light. It has been a much controverted question, whence does the heat proceed in this operation? The discussion is strictly chemical, and must therefore be dismissed with a few observation. A part of the heat liberated probably depends upon the less capacity of the product of combustion, than of the substance supporting it, *i. e.* of carbonic acid, than of oxygen and carbon separately; but there are instances in which the quantity of heat extricated appears to bear no proportion to the bulk of the materials consumed, or of carbonic acid formed; and hence we are induced to conjecture, that heat exists as an ingredient in combustible substances, and is disengaged from them in consequence of the changes of composition that take place. It has been supposed, that, besides what necessarily belongs to it as a gas, oxygen contains caloric as one of its constituents, which is liberated by a kind of precipitation; and the phenomena which attend the detonation of gunpowder lead us to conclude, that caloric also enters into the composition of the nitric salts, and others that possess similar properties. Of the heat produced by a change of capacity, in consequence of an alteration in the state of a body, or of new combinations, we have already spoken at sufficient length in the last Section.

There are few subjects connected with heat which are more inexplicable, than the manner in which it is generated by those means which appear to act mechanically, as friction, percussion, and condensation. The latter of these operations, condensation, has already come under our notice, in treating of the change of capacity which gases experience, according as their particles are compressed together, or allowed to expand themselves; and the same effect, at least to a certain extent, seems to follow from the condensation of solids. A very familiar instance of this occurs in the heating of a bar of iron merely by repeated hammering, where, by a few smart blows on the anvil, the smith is able to produce a sufficient extrication of heat to kindle a match. It is, however, known that iron does not possess this property of producing heat by being hammered, unless it has been previously heated for some time in the forge, and suffered to cool slowly in the air; and that, after it has been hammered, and lost part of its heat, its texture seems to become harder, and it is rendered less flexible than before the operation. The rolling out of metals into thin sheets or leaves, and the drawing of fine wires, likewise excite heat, which is to be referred to the compression the substance undergoes during these various operations. In all these cases there is some reason to suspect, that the bodies have had their capacity diminished, and that the heat, which becomes sensible, is to be assigned to this change. The effect of percussion may perhaps be explained on the same principle, as we may conceive, that, whenever percussion takes place, it must cause a proportionate condensation. It is to be remarked, that liquids seem to be incapable of extricating heat, either by any attempts at condensation, or by any kind of percussion; and as they are supposed to be nearly incompressible, we may conceive that their capacity is not liable to be affected by these means. Gases, however, which are readily compressible, are capable of having heat extricated from them, to a considerable amount, by condensation; and here we suppose that their capacities are changed, and in this way we account for the effect.

This mode of reasoning will not, however, apply to the extrication of heat which is caused by friction. The power of friction in producing heat, in various mechanical operations, is the subject of daily observation, and, if not prevented by different expedients, produces the most fatal consequences. The motion of wheels, and pulleys upon their axes, excites a degree of heat, which would quickly set fire to the machinery, was it not prevented by the application of different lubricating substances, which diminish the friction, by interposing between the hard surfaces a body which readily yields to the impression. The quantity of heat generated in these cases is so considerable, and seems so disproportioned to any effect that can be attributed to a change either in the capacity or chemical nature of the body employed, as to have been always regarded a serious objection to the hypothesis, which regards heat as a substance capable of being transferred from one body to another, like other material agents. The objection was reduced to a more palpable form by Rumford, who estimated the exact amount of the heat which was produced by a certain degree of friction, where all other extraneous sources for its admission were carefully guarded against. A piece of brass was fixed in a machine used for boring cannon, and a steel cylinder was pressed against the brass, with a weight equal to 1000 lbs. and then made to revolve on its axis with a given velocity. After some preparatory experiments, the apparatus was all inclosed in a vessel of water; and after the friction had been kept up for some time, the water was actually brought to the boiling heat. Here a very considerable quantity of heat was liberated, and the only mechanical change effected upon the materials was, that a quantity of brass turnings were formed; but neither these, nor the cylinder itself, appeared to have experienced any change, except a slight degree of compression. Rumford found by experiment, that the capacity of these turnings would not be affected by the operation; and the effect of the compression, which the metal had experienced must have been very inconsiderable. Yet the power of the substance to extricate heat was apparently unlimited; for there is no reason to suppose that any thing like exhaustion was produced, or that the apparatus would not have continued to evolve heat, until its texture had been destroyed, by the brass being all reduced into small fragments. (*Essays*, vol. ii. p. 469, *et. seq.*) Upon this experiment we shall offer some remarks in the next Section, where we treat upon the nature of heat.

The heat excited by the electric or galvanic shock has been commonly referred to a mechanical cause, although upon this point, a considerable diversity of opinions has prevailed. The effect, however, is well known to be very powerful, perhaps even more so than that produced by the convex lens; but it is still more confined as to the extent of its operation. If the two wires, in the interrupted galvanic circuit, be brought nearly into contact, and any substance, in very minute quantity, be placed upon them, it may be subjected to a temperature more intense than can be produced in any other manner; and by this means bodies have been burned or fused that had been before completely intractable. Whether in this operation the heat is, as it were, merely forced out of the wire by the commotion which its particles experience from the passage of the galvanic influence; or whether, as has been supposed, under certain circumstances, heat and electricity can be converted into each other, or may be separated by a kind of decomposition, are intricate questions of theory, upon which it seems at present beyond our power to decide, and which must depend very much upon the opinion that we entertain respecting the nature of heat. The simple facts, however, independent of hypothesis, seem to indicate, that heat and electricity are distinct from each other, whether they are to be regarded as species of subtile fluids, or only as properties of matter.

## SECT. IV.

### *On the Nature of Heat.*

After having made ourselves acquainted with the properties that are usually ascribed to heat, with the effects which it produces, and with the sources whence it is derived, we shall be more competent to enter upon the investigation of its nature. This has been a subject of discussion from the earliest period of philosophical inquiry, and is yet far from being determined; for although the most generally received opinion is in favour of its being a substance, capable of a separate existence, and possessed of a material, although very subtile nature; yet there are, on the contrary, many eminent men who regard it as merely a property, necessarily attached to other matter, and arising from some peculiar modification or affection of it.

The illustrious Bacon adopted this latter hypothesis, and conceived that heat depended upon a vibration of the particles of matter; an hypothesis which he endeavoured to substantiate by shewing, that whatever excited temperature, tended to produce a motion in the particles of the heated body. His description of this peculiar action is, that "heat is an expansive motion, restrained and resisting in the minute parts;" a phrase which, if expressed in modern language, would probably signify a reaction between the expansive power of heat, and the attractive force of the particles of matter towards each other. The idea of Bacon, that heat depends upon a vibratory motion among the particles of matter, received the powerful sanction of Boyle and Newton. As, however, observations on the phenomena of nature were multiplied, and especially as chemical science advanced, the hypothesis which considered heat as merely consisting in motion of the particles of matter, appeared less easy to reconcile with the new discoveries, and consequently a different doctrine was advanced, in which the effects of heat were attributed to a species of subtile fluid, of a proper material nature, although differing, in many important particulars, from any other kind of matter. The first writer who distinctly maintained this doctrine, and applied it in a philosophical manner to the explanation of facts, was Boerhaave; and it was, for the most part, embraced by the French. The general impression that was produced by Dr Black's discovery, was much in favour of the materiality of heat; and indeed it seems very difficult to imagine, how a mere property can be so exactly measured, and can be transferred from one body to another, at one time rendered latent, and again coming into action, without its quantity being either increased or diminished. The successive discoveries of Crawford and Irvine, together with the whole fabric of the Lavoisierian chemistry, strongly favour the same opinion; so that, in the present day, it must be regarded as the hypothesis which is by far the most generally received. It has, however, been zealously opposed by Rumford; and the experiments on the heat excited by friction, of which we have given an account, were brought forward as an unanswerable objection against it. Our limits will not permit us to take a very full view of all the arguments that have been urged on both sides of the question; but we must endeavour to give a sketch of some of the principal points that have been adduced by the advocates of each of the opinions. It will scarcely be denied, that if we admit the existence of a subtile elastic fluid, the particles of which are endowed with a repulsive power, which tends to unite itself to all kinds of matter, to insinuate itself into their pores, to produce their expansion, and, if added in sufficient quantity, to impart to them its own elastic nature, we are in possession of an agent, which very conveniently explains a great variety of phenomena; for, excepting the experiments of Rumford on friction, and others of a similar nature, we do not know of any facts which are averse to the supposition, or which are not better explained on this than on any other that has been adduced. It must, however, be admitted, that it is merely an hypothesis; and as there is no direct experiment which proves the existence of this subtile elastic fluid, it must be abandoned, if there be any single phenomenon which is absolutely irreconcilable to it. But before we can allow this to be the case, in the present instance, it is necessary to shew, that our acquaintance with the phenomenon in question is complete; that we thoroughly understand all its relations, and are competent to decide upon the connexion which it has with all the other actions to which it may be referred. Now we believe that few persons will assert that this is the case; on the other hand, we conceive every one will admit, that any attempt to explain the intimate nature of the motion supposed to produce heat, and the manner in which vibrations can excite a sensation such as that which we refer to this principle, must be a most arduous task. Still more so will it be to explain, how it can be the immediate cause of liquidity and of elastic fluidity; how it can be transferred in definite quantities from one body to another; how this can be done even while it is lying dormant, or while we have no proof that the motion actually exists. In short, we shall find, that the hypothesis of vibrations is far from being unencumbered with difficulties; and that we have only removed one, to become involved in a much greater number. Besides, although we have admitted that there is no direct experiment to prove the independent existence of heat, or at least none against which some exception has not been taken; yet there are facts brought forward, perhaps as decisive on this side of the question, as those respecting friction are on the other. We refer to the transmission of heat through a vacuum. Pictet proved that this takes place in the vacuum of the air-pump; and Rumford, the great advocate for the immateriality of heat, has shewn that it is capable of passing even through the Torricellian vacuum. There seems no method of reconciling this fact with the hypothesis, except by taking for granted the existence of some kind of vapour or elastic fluid, along which it is propagated; a supposition equally gratuitous, and equally unsupported by direct and independent facts as that for which it is substituted. Indeed, the same remark may be applied to all the phenomena in which the radiation of heat is concerned; it seems extremely improbable, if not impossible, that these rays are carried along by the air, even when near the surface of the earth, and they must necessarily traverse an immense track totally devoid of air. If we, in this case, suppose the existence of a subtile medium, invented for the purpose of carrying them through space, we are here, as in the former instance, creating an agent at least as hypothetical as the matter of heat. Upon the whole, we are strongly inclined to the opinion which regards heat as an elastic fluid, of a proper immaterial nature, although of extreme subtilty, the particles of which are repulsive with respect to each other, but are attracted by other bodies, with different degrees of force, according to their respective nature.

Before we conclude this discussion concerning the immateriality of heat, it will be proper to notice the experiments which have been made, in order to ascertain whether it be actually possessed of gravity, or rather, whether its weight can be measured by a balance. The best contrived experiments of this description were those of Fordyce. He very carefully weighed a quantity of water, froze the water, and then again weighed it. Now he argued, that in this process, the water must have parted with the latent heat which maintains it in the liquid form; so that if heat be a ponderable substance, it might be expected that the ice would exhibit a diminution in its weight, equivalent to that of the caloric which had escaped. The result, however, did not correspond with this idea; and indeed, in some of the most accurate trials, it seemed as if the body that had parted with its heat had even acquired a slight addition of weight. It is, however, generally admitted, that no decisive conclusion can be drawn from such experiments; and that, from the conception that we have of the extreme tenuity of the particles of heat, it is not probable, that any portion which we can have it in our power to impart to a body, could be detected by the instruments that we employ in ascertaining the weight of bodies. Our preference, as we stated above, is certainly in favour of the hypothesis of the materiality of heat; because we think it explains the phenomena in general with greater facility, and is encumbered with less difficulties than the immaterial hypothesis. Yet we must remember, that it is not decisively proved by any direct and unexceptionable experiments; and it must also be acknowledged, that it has not received the sanction of some eminent philosophers, both at the revival of letters and in our own times. We have already mentioned the opinion of Rumford; and Professor Leslie, to whom science is so peculiarly indebted for his numerous experiments and discoveries on the subject of heat, also adopts the hypothesis, which ascribes its effects to a certain motion among the particles of bodies. He conceives that the propagation and transmission of heat, is very similar to that of sound, and that it in fact consists in certain aerial undulations. A hot body communicates a portion of its heat to the contiguous stratum of air; this immediately expands, and by this expansion, a vibration is excited in the adjoining stratum; this is propagated to the next, and so on until the equilibrium is produced. The passage of heat is therefore of the same velocity with the undulation of the air, or rather is identical with it; and according as the surfaces of bodies act upon the air in contact with them, so will they radiate heat with greater or less readiness. The facility of radiation is supposed to be principally owing to the approximation of the air to the surface; those bodies radiating the best, to which the air comes into the closest contact. This view of the subject explains why the best radiators should likewise be the best absorbers of heat; and it is also supposed to afford a reason for the effect of roughening the surface, or covering it with substances which destroy its polish. Professor Leslie seems to have advanced his hypothesis, merely as a convenient manner of accounting for some of his own experiments; he has not stated it in such a way as to apply to all the phenomena of heat, nor has he attempted to reconcile it with the experiments of Herschel, and others which appear decidedly adverse to it. Indeed, we much doubt whether it can be adapted even to some of his own experiments on the radiation and reflection of heat; for it must be supposed, that the undulations of the air are propelled from the surface of bodies, impinge upon others, and are again reflected, exactly as they radiate heat, with the same velocity, and in the same direction; a circumstance which we apprehend it would be extremely difficult to prove. It may be farther remarked, that although Professor Leslie's hypothesis supposes that the undulations of the air are the cause of heat, or that which produces the phenomena in question; yet there are many expressions which would seem to imply, that this heat is something distinct from the undulations themselves, and that the heat is transferred or transmitted from one wave to the other, not that the waves are themselves the actual cause of the effect. The farther consideration of this question would involve us in a discussion that would exceed the limits to which we are necessarily restricted.

In the former part of this article we alluded to the chemical properties of heat, but we proposed to defer the consideration of them until we had made ourselves more fully acquainted with its nature and its effects. On this subject there are two points to be determined: first, Does heat possess any properties, or any relation to other bodies, which can strictly be called chemical? And secondly, What are these relations? When we speak of a substance being possessed of chemical properties, we mean, that by its being separated from or added to another substance, the two substances, in the case of their decomposition, or in the other case, the compound of the two, manifest different chemical relations from those which they possessed before the operation. By some philosophers it has been supposed that this change takes place with respect to heat, that when it enters into combination with a body, as for example with oxygen, and forms oxygen gas, a compound is produced, possessed of new properties that are not merely mechanical, while at the same time the heat itself has entirely lost its former qualities by its union with the oxygen, and like other bodies, after a chemical composition, has imparted to the compound properties quite different from its own. If we again decompose the oxygen gas, as by uniting its base to carbon, the heat is precipitated, and resumes all its former properties, which had been entirely destroyed, or rendered latent, while it remained in the combined state. But although there may appear to be a considerable degree of plausibility in this method of reasoning, it has not been generally acquiesced in. The great objection which has been urged against the opinion, that heat unites chemically to bodies, is, that it may, in all cases, be separated from them, merely by a reduction of temperature, without the intervention of a more powerful affinity; a circumstance which is conceived to be essential to a proper chemical decomposition. With respect to the new properties which heat imparts to other substances, by its union with them, these have been said to be merely mechanical, or to be such as must necessarily result from these particles being placed at a greater distance from each other. As to the heat itself, there is undoubtedly something more analogous to chemical union, in the changes which it experiences; as by entering into combination with other bodies, its characteristic properties are all destroyed. Yet this involves a discussion rather about words than ideas, and in a great measure depends upon the meaning which we attach to certain modes of expression. The fact is, that heat seems to have electrive attractions for different bodies, independent of any of their relations to other substances; that it combines with them, and produces a change in their state, which perhaps may be regarded as merely mechanical; but that by these combinations its action is destroyed, and it no longer possesses the properties it previously exhibited. Upon the whole, we are inclined to the opinion, that the effects of heat are not referable to the usual laws of chemical affinity, but must be referred, partly to those of mechanical impulse, and partly to what we may denominate specific action, *i. e.* an action peculiar to itself, and essentially different from what we can observe in other natural objects. See our articles COLD and EXPANSION. (α)

## APPENDIX.

In the preceding article, we have given an account of the experiments of Dr Herschel, Sir H. Englefield, and M. Berard, from which it follows, that there exists beyond the red extremity of the spectrum a set of invisible rays, which affect the thermometer more powerfully than even the red light of the spectrum.

These experiments were repeated, under the most favourable circumstances, by our celebrated countryman Sir H. Davy, who favoured us with an account of them when we had the pleasure of seeing him at Geneva. Availing himself of the fine climate and the serene sky of Italy, he resolved to inquire into the cause of the difference between the results obtained by Dr Herschel and Berard; the former having placed the point of maximum intensity beyond the red rays, while the latter found the heat greatest within the extremity of the red space. It occurred to Sir Humphry, that thermometers with circular balls of the size used by Berard must necessarily shew the maximum of heat to be within the red space, as a cooling agency must always be exerted by that part of the bulb which is out of the limits of the calorific rays; and hence the diminution of temperature which this occasioned would compensate for the greater effect produced by the invisible rays. In order to remove this source of error, Sir H. Davy employed extremely slender thermometers, not more than $\frac{1}{12}$th of an inch in diameter, with very long bulbs filled with air confined by a coloured fluid; and in this way the bulb was affected only by the invisible rays. The general results of these experiments, which were repeated also at Geneva, confirmed those of Dr Herschel, and may be considered as removing the objection of Professor Leslie, that, in our climate particularly, there must always be a concentration of extraneous light beyond the red extremity of the spectrum.

We regard it, therefore, as a point established in physics, that there is a distinct effect produced upon the thermometer beyond the red extremity of the spectrum; but we cannot admit for a moment the conclusion which has been universally drawn from it, that it is produced by a separate set of heat-making rays, refracted by the prism, and having a greater refrangibility than red light. Dr Herschel has attempted to prove that invisible culinary heat is also susceptible of refraction like the invisible rays, and M. Prevost and M. Delaroche have likewise endeavoured to shew that this kind of heat is capable of permeating glass. We have no doubt that this opinion will be found to be erroneous, and we think it is demonstrated,* that invisible culinary heat is incapable of refraction, or of permeating glass like light, and hence we cannot suppose that the invisible rays of the sun are capable of being refracted by glass. If this shall be found to be the case, it will follow that the invisible heat of the sun is a substance possessing properties essentially different from those of invisible culinary heat. As radiant heat, therefore, possesses very different properties from light, we think it will be found, that light, like all other matter, whether gaseous, fluid, or solid, is capable of being heated, and that the solar rays are nothing more than *heated light*. Hence the least refrangible rays, having the greatest velocity, or momentum, will produce the most powerful calorific effect. We shall have occasion to resume this subject in another part of our work. See OPTICS. ED.

# INDEX.

---

HEBREWS. See Jews.

HEBRIDES. See Argyleshire, Arran, Bute, Staffa, and Scotland.

HEBRIDES, New, a cluster of above twenty islands in the south Pacific Ocean, extending about 375 miles in a direction from N. W. to S. E. and situated from 14° 29′ to 20° 4′ S. Lat. and 166° 41″ to 170° 21′ E. Longitude.

The appellation which is now bestowed on this group, results from its complete recognition by Captain Cooke in 1774. So long ago as the year 1606, the Spanish navigator Quiros landed on the most northern island, which he seems to have considered as a continent, and called it *Tierra Austral del Espiritu Santo*, or the southern land of the Holy Ghost. Bougainville, in his voyage of discovery in 1768, found it an island; and after a partial examination of the group, named it the Archipelago of the Great Cyclades; but almost all geographers seem inclined to admit the nomenclature of Captain Cook, who was occupied 46 days in the survey; and considering these islands the most western of the Pacific, he named them Hebrides. Nevertheless, Fleurieu questions Captain Cook's right to change the appellation of Great Cyclades, bestowed by Bougainville, and expresses a hope that the name given by both will be superseded, by restoring that of Quiros.

These islands are of unequal dimensions, and separated from each other by channels of different breadth. But the following list, obtained from collating the narratives of successive navigators, will more briefly explain these peculiarities, making some allowances for the whole not being seen exactly under the same aspect.

Pic d'Etoile, 14° 29′ S. Lat. 168° 9′ E. Long.—Tierra Austral, 66 miles long, 36 broad. St Bartholomew.—Isle of Lepers, 54 to 60 miles in circuit, 15° 20′ S. Lat. 168° 31′ E. Long. Aurora Island, 36 miles long, 5 broad, 15° 6′ S. Lat. 168° 24′ E. Long. Whitsuntide Isle, 33 miles long, 8 broad, 15° 45′ S. Lat. 168° 28′ E. Long. Mallicolo, 54 miles long, 24 broad, 15° 50′ S. Lat. 169° 38′ E. Long. Ambrym, 60 miles in circuit, 16° 15′ S. Lat. 168° 20′ E. Long. Apee, 60 miles in circuit, 16° 42′ S. Lat. 168° 36′ E. Long. Paoom, 15 miles in circuit. Three Hills Island, 12 or 15 miles in circuit, 17° 4′ S. Lat. 168° 32′ E. Long. Shepherds Isles. Monument. Two Hills.—Montague Isle, 9 miles in circuit. Hinchinbrook Isle, 14 miles in circuit. Sandwich Island, 75 miles in circuit, 17° 40′ S. Lat. 168° 30′ E. Long. Erromango, 90 miles in circuit, 18° 48′ S. Lat. 169° 20′ E Long. Tanna, 72 miles in circuit, 19° 30′ S. Lat. 169° 38′ E. Long. Irronan.—Immer, 15 miles in circuit. Annatom, 30 to 36 miles in circuit, 20° 3′ S. Lat. 170° 5′ E. Long.

Some of these islands contain volcanoes, such as Ambrym and Tanna; that on the latter throws up prodigious columns of fire and smoke, attended with loud explosions at frequent intervals, and huge stones are sometimes seen in the air. Native sulphur is found on the island, and nephitic vapours arise from the ground. Quiros affirms that he and another Captain saw silver and gold on the Tierra Austral; but this has not been confirmed; nor are we particularly acquainted with the mineralogy of the New Hebrides, unless in their exhibiting volcanic products, red ochre, and chalk. Hot springs issue from the rocks of Tanna, raising the thermometer to 202°.

Vegetables grow throughout these islands in great profusion and variety. Quiros, who wrote a recommendatory memoir to his own court, regarding the island upon which he landed, describes it as of greater fertility than Spain; and later navigators have remarked, that the hills of other islands were covered with woods to the very top. Trees occur 150 feet high. Figs, nutmegs, and oranges, which Captain Cook found no where besides, grow here, as well as cocoa-nuts, bananas, the bread-fruit, and the sugar-cane.

Fish are numerous on the shores, but many are poisonous; and the crews of different ships have suffered severely, though not fatally, from having fed upon them.

Large and beautiful parroquets, of black, red, and yellow plumage, are seen on the islands; and, among other birds, that species of pigeon which feeds on the nutmeg, and is described by Rumphius as disseminating the real plant in the Spice Islands. Quiros speaks of goats; but the only quadrupeds observed by later visitors are hogs and rats. No dogs have been observed by strangers on any of the islands visited by them; nor have the natives any name for the animal, which shews that it is unknown.

The New Hebrides are evidently inhabited by different races of people, whose origin some navigators are inclined to derive from Papua or New Guinea. None possess that symmetry and stature seen in other parts of the Southern Pacific Ocean. Those of the Tierra del Espiritu Santo seem more robust and better formed than most of the rest. Bougainville describes the natives of Lepers Isle as small, ugly, and ill made, and the few women observed were altogether as disgusting as the men. The inhabitants of Tanna are of middle size, their limbs well made and rather slender; and some are tall, stout, and strong. Their features are large, the nose broad, eyes full, and in general with an agreeable expression. The hair is black; but, in several instances, with brown or yellow tips. Brown and reddish hair has appeared here and elsewhere; but it is frizzled and woolly for the most part. The women of the Mallicolese present the most disagreeable features of any seen in the South Seas; and the daubing of their whole bodies, or covering their heads with the orange powder of turmeric root, has a dirty appearance. All the inhabitants of the group are of a deep chesnut brown colour, and their skin is uncommonly soft and smooth to the touch. M. de Bougainville says, those of Lepers Isle are of a black or Mulatto colour, the hair of some being a yellow wool, which, it is not unlikely, might have been the consequence of disease, as he gave the island its name from the inhabitants being much afflicted with leprosy.

The language of the New Hebridians is different from that of all the other tribes of the South Sea; it abounds in consonants, and even in the united duplication or triplication of them. But they have a remarkable facility in understanding and imitating strangers, and have a very quick and ready apprehension. Their admiration is expressed by hissing like a goose. They are singularly honest, unlike all savages; and most of them have a manly, good natured, open aspect.

In general these people go nearly naked; boys and girls absolutely so. The greater part of the women have a short petticoat; many only a cord about the body, with a bunch of straw. A decided characteristic of the Hebridians consists in a rope tied round the middle, which, being put on at a very early age, makes a deep groove, dividing the belly as it were into two parts, so that the one almost overhangs the other. Captain Cook, in describing the Mallicolese as "the most ugly and ill-proportioned people I ever saw, and in every respect different from any we had met with in this sea," and specifying "their long heads, flat faces, and monkey countenances," continues, "but what most adds to their deformity, is a belt or cord which they wear round the waist, and tie so tight over the belly, that the shape of their bodies is not unlike that of an overgrown pismire." They are less acquainted with the art of tattooing than many other islanders, and they obtain a similar effect by incisions of the flesh, producing elevated scars, which resemble external objects. A number of personal ornaments are employed by them, more generally by the men than the women. The face and body are frequently painted black, brown, or red; and bracelets, ear-rings, or a bone through the nose, are worn among both sexes. The women and children are in general shy; the former are held in subserviency by the men, and condemned to the more laborious operations.

The disposition of the Hebridians seems to be courteous and liberal; they are not equally prone to revenge injuries, as many other savages, and are more willing to be satisfied. The English circumnavigators were treated with great hospitality, and it seems doubtful in any misunderstandings which was the aggressor. M. de Bougainville considered an attack on him at the isle of Lepers, followed by a flight of arrows, as the consequence of premeditation. They are evidently often at war, from the number and variety of their arms; and during the visits of strangers, they are always on the watch, keeping their bows constantly bent. These are very strong and elastic; made of the best club wood, and highly polished. The arrows are made of reeds nearly four feet long, and pointed with a piece of hard brittle black wood, twelve or fifteen inches in length. Some have three points for shooting birds, others are discharged at fish, and pointed with a bit of bone two or three inches long. They have also clubs, spears, and darts; the first of different sizes and shapes, from two feet and a half in length to six feet, and are slung from the right shoulder by a rope. Their arrows are shot with great force and precision to the distance of 8 or 10 yards, but are little to be dreaded at 25 or 30. Their darts also are thrown with much power and accuracy to a short distance. Some arrows exhibit a greenish gummy substance on the points, which the natives affirm is poison; but in experiments made with it by the English on animals it was not fatal.

The arts are in a very low state; navigation is little understood, and fishing seldom resorted to. No fishing tackle whatever was observed by the English in the largest islands; and their canoes consisted of several pieces of wood clumsily sewed together. Only 14 belonged to the whole island of Mallicolo. However, that of Immer is chiefly inhabited by fishermen, and the various canoes are from 20 to 30 feet long, but all of indifferent workmanship. The dwellings on shore are miserable huts of rude construction, or, properly speaking, large sheds about 35 feet long, open at both ends, and of which the roof, ridged at top, reaches to the very ground. Captain Cook compares them to a house without walls. They seem to contain no furniture except mats, palm leaves, and dry grass, which cover the floor. The quality of the climate is such that the inhabitants can almost dispense with artificial shelter, and all their pursuits concentrate in warfare and in procuring subsistence.

A large portion of the New Hebrides is well cultivated. Whole islands are covered by woods and divisions, indicating much industry, and a correct notion of property; and extensive grounds are laid out in regular plantations of the sugar-cane, bananas, and plantains, all kept in good order, and sometimes protected by stone fences two feet high.

It is not ascertained that the natives have any religion, or any form of government. They offer the branch of a tree as a sign of pacification, and pour water on their heads, as indicating a desire for conciliation, or in token of contrition. They dance round fires to the sound of drums; and these are heard in the woods on occasions of alarm. Their music is of a lively turn; they have pleasing airs embracing a considerable compass, and it is said they sing in parts,—a fact worthy of being ascertained, as the music of savages is so limited. An instrument consisting of eight reeds, like the syrinx or Pan's pipe, and extending throughout an octave, has been seen here.

It is singular, that in some of the islands, as Tanna, iron is of no value, while in others it bears the highest price. Looking-glasses prove the source of great amusement to the natives, and their complacent self-contemplations have induced their visitors to affirm that they are extremely conceited.

All those who have reached the New Hebrides bestow the warmest commendations on their soil, climate, and productions. The later navigators have thought that a settlement might be profitably made on Sandwich Island; and Quiros, two centuries ago, sought to interest the avaricious court of Spain, by pointing out the benefit which would result from one on the Tierra Austral del Espiritu Santo. "In a word," he says, "the union of so many advantages would produce such power and riches, that these territories would not only support themselves, but afford an overplus for the assistance of America, aggrandize your majesty's dominions in general, and very speedily elevate Spain to the highest degree of prosperity. All this I will undertake to answer for, if I shall be assisted and supported in my enterprise." The north side of the island is penetrated by a capacious bay, which he considers capable of being a harbour for 1000 vessels; and after acquainting his sovereign, that, amidst its numerous properties, "the dawn is ushered in by a most delightful concert of millions of birds from the forests wherewith the shores are shaded, and that every evening and morning the air is perfumed with the odours of all species of flowers intermixed with those of aromatic plants," he concludes with these words: "Finally, sire, I can with confidence assert, that this harbour, which is situated in 15° 20′ South Latitude, presents the greatest natural advantages for the establishment of a large city and a numerous colony."

None of these anticipations, however, have been realised, and the New Hebrides, yet unoccupied by Europeans, are only resorted to, as we learn, at rare intervals, for cargoes of wood from their forests.

Navigators have been so much mistaken regarding the population of the South Sea Islands, as to warn us against listening to conjectures. The inhabitants of Mallicollo were computed at 50,000 in 1773, and those of Tanna at 20,000; but we cannot forget, that while about the same time the population of Otaheite was supposed above 200,000, calculations of tolerable accuracy reduce it at this day to 5000; towards which, however, several causes, perhaps unknown to the New Hebridians, may have contributed. HEDWIG, John, a celebrated botanist, was born at Cronstadt in Transylvania, on the 8th of October 1730, and was the son of one of the magistrates of that town. His love of botanical pursuits shewed itself at an early period; and while his school-fellows were busy with their amusements, Hedwig was actively employed in collecting wild plants, and transplanting them to his father's garden. After studying four years at the public school of Cronstadt, he was enabled, notwithstanding the loss of his father in 1747, to go to the university of Presburg to continue his studies. He remained here two years following his medical pursuits, and then went to Zittau to attend the lectures of Gerlach. In 1752, he entered himself as a student at the university of Leipsic, and attended the lectures on medicine, philosophy, and mathematics. Here he gained the particular friendship of the celebrated Ludwig; and such was the opinion entertained of him by Bose, the professor of botany, that in 1756 he took him into his own house, gave him the charge of his garden, and allowed him, during three years, to attend for him at the hospital. Upon the completion of his studies, he was naturally anxious to settle as a physician in his native place; but upon applying for license to the magistrates, he was mortified to find that no physicians could practise in Transylvania, who had not been members of the university of Vienna. His friend Bose, however, having advised him to commence practice in some small town in Saxony, he presented his dissertation *sur l'emploi des emetiques dans les fievres aigues*, and was admitted doctor of medicine. Having a friend resident at Chemnitz, he fixed upon that town, where he settled, after marrying Miss Sophia Teller, a lady from Leipsic. Hedwig now devoted his mornings to the collection of plants, and his evenings to their examination, while the rest of the day was employed in his professional pursuits. The cryptogamic plants particularly attracted his attention; and having had occasion to write to the celebrated Schieber, who was then publishing the Flora of Leipsic, for the explanation of some difficulties, a correspondence immediately commenced between them, and Hedwig received from his friend several books, a single microscope, and afterwards a compound one made by Rienthaler the optician. By means of this instrument, on which he made some improvements, he was enabled to determine the male and female flowers of the mosses. See our article Botany, and Musci.

His wife, who had brought him nine children, died in 1776; and though he was oppressed with grief at such a loss, yet as he was unable to continue his pursuits, and attend to the education of his six surviving children, he yielded to the advice of his friends, and married, in 1777, Miss Salzberger of Leipsic. In 1779, he published at Leipsic, in a German periodical work, his great discovery, under the title of "Observations on the true parts of generation in Mosses, and on the Multiplication of Mosses by seed." At the urgent desire of his wife, who considered his talents as lost at Chemnitz, he removed to Leipsic in 1781, and in the following year he published his work, entitled *Fundamentum Historiæ naturalis Muscorum frondosorum*, illustrated with 20 coloured plates.

The Petersburg academy having offered a prize of 100 gold ducats, for a determination of the parts of fructification of the cryptogamic plants, Hedwig sent a large treatise on the subject, which gained the prize, and which was published at St Petersburg, in 1784, under the title of *Theoria generationis et fructificationis plantarum Cryptogamicarum Linnæi*. A new and enlarged edition of this work afterwards appeared in 1798.

Hitherto Hedwig had lived in a state of obscure poverty; but his talents were now about to receive their proper reward. In 1784, he was made inspector of the military hospital at Leipsic, and in 1786 he was appointed professor extraordinary to the faculty of medicine. In 1789, Frederick Augustus, elector of Saxony, nominated him professor of botany, and superintendant of the public garden, and at the same time gave him apartments at the academy.

Having been occupied more than 35 years in the study of nature, Hedwig published the results of his observations in the following treatises.

1. A Treatise on the origin of the parts of fructification, in which he shows that the stamens and pistils are not produced by the pith, as Linnæus believed, but by the same vessels as the other parts of the plant.
2. A Memoir on the Cotyledons.
3. A Dissertation on Bulbiferous Plants.
4. A Memoir on the Organs of Transpiration in Plants.
5. An Examination of the distinctive characters of Plants and Animals.
6. An Answer to certain Questions proposed by Dr Arthur Young, on the Irrigation of Meadows with spring water.
7. A Dissertation on the Origin of the Vegetable Fibre.
8. Observations on the use of the Leaves in Plants.
9. A Memoir, in which, after having described the sexual organs of several *Cucurbitacea* at the time of fecundation, he considers the manner in which the pollen impregnates the ovaries, and the changes which this phenomenon produces in plants.
10. Notes on the Aphorisms of Humboldt, in which he lays down several principles of vegetable physiology.
11. Lastly, Considerations on the present and future state of the Science of Botany, and on the best means to be pursued in the study of it.

Between the years 1787 and 1797, Hedwig published his great work, entitled *Descriptio et Adumbratio Microscopica analytica Muscorum frondosorum, nec non aliorum Vegetantium, classe Cryptogamica Linnæi novorum dubiisque nexatorum*, in 4 vols. folio, the first of which appeared in 1787, and the last in 1797. This work contains an analytical description of 148 species of mosses, and 50 other cryptogamic plants, all of which were examined with the microscope, and figured with great elegance and truth. Each volume is illustrated with 40 excellent coloured plates. He likewise prepared a general History of the Mosses; but this work, which he did not live to finish, was arranged and published by Frederick Schwægricher, one of his pupils. It contains notices of 360 species, of which 157 are figured. Out of six children by his second wife, five died at an early age, and one of his daughters, whose education he had superintended, was carried off by the small-pox in December 1797. This severe blow affected his health: and having neglected to take proper care of himself during the severe weather of 1798 when he was visiting his patients, he was attacked by a catarrhal fever, from which he had scarcely recovered, when he was carried off by a nervous fever, on the 7th of February 1799, in the 69th year of his age. Out of 15 children, only four survived him, two sons and two daughters. One of his sons, M. Romain Adolphus, professor of botany at Leipsic, published two fasciculi of a splendid work on ferns, with coloured plates; but he did not long survive his father.

Hedwig was distinguished by all the social virtues. He was neither elevated by the high reputation which he had acquired, nor depressed by the illiberal criticisms with which he was assailed. His enjoyments and his sufferings were of a higher class. They were the luxuries and the sorrows of domestic life. See Deleuze's *Account of the Life and Writings of Hedwig*, published in the *Annales du Museum d'Histoire Naturelle*, vol. ii. and in Brande's *Journal of Science and the Arts*, vol. i. p. 103.

HEGIRA, or Hejera, is an epoch to which the Arabs and Mahometans refer historical events. It comes from an Arabic word, which signifies *fled*, and the epoch is dated from the night between the 15th and 16th July A. D. 622, when Mahomet was forced to leave Mecca to avoid the persecutions of his enemies. The year of the Christian era, corresponding to any year of the Hegira, may be found by the following formula, H being the year of the Hegira, and C that of the Christian æra, $C = \frac{H \times 354}{365} + 622$, or $C = H \times .9692 + 622$. Thus if we wish to know what year of our æra corresponds with the year of the Hegira 1232, we have $C = 1232 \times .9692 + 622 = 1816$.

Tables shewing the correspondence between the years of the Hegira and those of the Christian æra have been given by Greaves in his *Epochæ Celebriores*; by Riccioli in his *Chronologia Reformata*, 1659; and by Beckius in his *Ephemerides*, 1695. A more correct table has been published by Mr Marsden, in his paper *On the Æra of the Mahometans called the Hejera*, printed in the *Philosophical Tansactions* for 1788, vol. lxxviii. p. 414, or in the abridgment, vol. xvi. p. 509.

HEIDELBERG, is a city of Germany, in the circle of the Lower Rhine, formerly the capital of the Palatinate, and recently forming a part of the grand duchy of Baden. It is a long and narrow town, and is situated at the foot of a mountain on the south side of the Neckar. This river is crossed by a fine bridge, which cost 170,000 florins, and from which there is a fine view upon the river. It is surrounded with walls, which have six gates. The citadel, called Fort l'Etoile, was long ago destroyed by the French. It contains three churches for Roman Catholics and Protestants, an university, an economical society, an anatomical theatre, a military hospital, a cabinet of mineral models and physical instruments, a botanical garden, and more than 20 fountains. The university was founded in 1386, and has been under the direction of 20 professors, 16 Catholic, and four Reformed. When the Bavarians took it in 1622, its library was transferred to the Vatican, by Robert Maximilian of Bavaria. The fine statue of the Elector, the church of St Esprit, the church of St Peter, with the sepulchral inscription of the celebrated Olympia Fulvia Morata, are worthy of being seen. The castle and the garden of Heidelberg, situated near the town, are now in ruins. The statues of the ancient Electors and Count Palatines are still to be seen on the front of the castle; the remains of the hall of the chevaliers are still visible; and the granite columns, which formerly supported a part of the imperial palace at Ingelheim near Mayence, are seen supporting the roof of the fountain of the castle. The subterraneous passage extends to the great square in the town. A Restaurateur is now established in the middle of these ruins. Heidelberg has been celebrated for its wines, called *vin du Necker*, obtained from grapes which grow on both sides of the mountain; and for its capacious tun, which originally contained 528 hogsheads, and 600 when it was rebuilt, and which is still shown to strangers. It has manufactures of camblets, silk stockings, and silk handkerchiefs, wax lights, soap, cotton, clothing, paper hangings. The population, which is principally Lutheran, amounts to 12,000.

HEIGHTS. Methods of measuring heights by the Barometer will be found in our article Pneumatics, and trigonometrically in our article Trigonometry.

HEILBROUN, or Hailbron, is a town of Germany in Suabia, which belonged to the King of Wirtemberg. It is situated in a very pleasant and fertile country on the banks of the Necker, which is crossed by a covered stone bridge. The town is strong and well built, and has some fortifications, three churches, two convents, and public baths. The principal objects of curiosity in this town are, the Gothic tower of the church of St Kilian, which is remarkable for its architecture, the public library, the house of correction, the great fountain, and the fine promenade before the gates of the town. In the archives of the town are preserved the letters of the two celebrated Chevaliers François de Sickengen and Goez de Berlichingen, the last of whom was imprisoned in a tower, which still remains, and was interred in the convent of Schoenthal near the town. The town carries on a great trade in tartar and all sorts of glass. It contains distilleries of brandy, paper manufactories, tanneries, oil mills, and wheels for tobacco. Population, 8000.

HELENA, St, generally ranked by geographers among the islands of Lower Guinea, is situated in 15° 55′ South Latitude, and 5° 49′ 45″ West Longitude from Greenwich. It is 600 miles from Ascension Island, the nearest land, 1200 from the coast of Africa, and nearly 2000 from that of America. In sailing from Europe, it is generally necessary, in order to make the island, to stretch along the Brazil coast quite out of the tropics, till it can be gained by the aid of the south-east trade winds; but of late years the inner or easternmost passage has frequently been followed, and has not uncommonly been made in 7 or 8 weeks from England. A bird, called the St Helena pigeon, which is seen only to the windward of the island, generally indicates its vicinity to the navigator, long before the land can be discerned by the telescope.

St Helena was discovered by the Portuguese commander John de Nova, on St Helen's day, May 21st 1501. It was then inhabited only by seals, sea-lions, sea-fowls, and turtles. The interior of the island was one entire forest, and even many of the rocky precipices on the coast were covered to the brink with the gum wood tree. Its first settlement and improvement are ascribed to the following interesting occurrence: Several Portuguese noblemen, who had deserted in India to the native princes, were punished by Albuquerque in the most cruel manner, by having their noses, ears, and right hands cut off; and in this mutilated condition, were put on board the ships returning to Europe. Fernandez Lopez, one of the sufferers, preferring a voluntary exile to a life of ignomy in his native country, was at his own request, landed on the island of St Helena in the year 1513, with a few negro slaves. Many of his countrymen, commiserating his sufferings, exerted themselves to contribute every comfort and convenience which his forlorn situation would admit. Hogs, goats, and poultry, were landed for his sustenance. Partridges, pheasants, guinea-fowls, peacocks and other wild fowl, were let loose in the woods. Figs, oranges, lemons, peach trees, and various vegetables, were planted in the infant soil. By his skill in botany and gardening, the fruit trees were brought to great perfection; and the live stock and feathered tribes increased so abundantly under his protection, that in a short time they entirely overspread the face of the country. After a residence of four years, Fernandez was removed from the island by orders from the court of Portugal; but the spots which he had cultivated continued to supply the ships of his country with seasonable and abundant refreshments in their Indian voyages.

The Portuguese succeeded in concealing the situation of St Helena from other European nations till the year 1588, when it was descried and visited by Captain Cavendish on his return from a voyage round the world. It soon became well known also to the Dutch and Spaniards; and the crews of the different nations are accused of having wantonly laid waste the plantations, and destroyed the live stock, as if grudging to succeeding visitors any participation of the benefits which themselves had enjoyed. After the Portuguese had acquired so many ports on the eastern shores of Africa, they removed entirely from St Helena, which remained for a long time in a desolate condition; but, according to other accounts, they were expelled from it by the Dutch, by whom it was again abandoned upon the establishment of their colony at the Cape of Good Hope in 1651. Upon their departure, the English East India Company immediately formed a settlement upon St Helena; and about ten years afterwards, obtained a charter for its possession from Charles II. Many settlers were induced, by the offer of lands, to emigrate thither from England; and slaves were imported from Madagascar to work in the plantations. In 1665, the Dutch succeeded in an attack upon the island, but in a few months were obliged to give place to the English; and after the destructive fire in London in 1666, numbers of the ruined families, who sought relief in distant countries, removed to the new settlement on St Helena. It was once more retaken by the Dutch in 1672, through the treachery of one of the planters, but was almost immediately recovered by an English squadron under Captain Munden, and again restored to the East India Company. The first fortification was erected by the English in 1665, and a few lines formed across the valleys, and batteries, slightly elevated above the level of the sea, were at different times constructed; but more than a century was suffered to elapse before its impregnable heights were employed as posts of defence.

Till the beginning of the 18th century, the history of the settlement contains little else than a succession of petty contentions, insurrections, and mutinies. A general spirit of insubordination appears to have infected all ranks on the island, planters, soldiers, and slaves; and though every attention was paid by the Company to support the interests of good order, morality, and religion, yet two causes chiefly seem to have defeated all the good effects of their regulations, viz. the injudicious conduct of the governors in failing to check the first symptoms of disaffection, and the profligate character of the persons who presided over the religious instruction of the inhabitants. An abundant distillation of spirits from potatoes was no inconsiderable auxiliary to the spirit of disorder; and this source of depravity became at length so great a nuisance, that, in the year 1700, all the stills were suppressed by an order from England. But, by the wise and vigorous measures of Governor Roberts, from 1708 to 1714, and by the pious exertions of Mr Tomlinson the chaplain, a degree of tranquillity hitherto unknown was established in the settlement, and a new æra commenced in the history of the island. The Company's lands were brought into a promising state of improvement; planting and inclosing encouraged among the settlers; the culture of vines and sugar canes introduced; lime quarries discovered and wrought; a manufactory of bricks and tiles set on foot; a code of the existing statutes arranged and published for the information of the inhabitants; and the exercise of martial law in a great measure abolished, except in times of alarm or attack.

From the year 1727 to 1731, great encouragement was given under Governor Byfield to the planting of furze fences, both with a view to afford protection to the lands, and to secure a supply of fuel. The increase of trees also was greatly favoured by a resolution to withhold the liberty of keeping sheep and goats, which were so injurious to the young plantations; and in place of the general privilege, grants were given to individuals of keeping goats on certain parts of the Company's waste lands, called goat-ranges. About the year 1749, the Scotch and spruce firs were introduced by Governor Hutchinson; and acorns were at the same time planted, from which oaks have grown to the size of 8 or 11 feet in circumference. The same gentleman succeeded, after repeated attempts, in introducing the coffee plant, which is now regularly cultivated. The importance of St Helena became daily more manifest, as the trade and prosperity of the East India Company increased; and, in the year 1759, many important regulations were introduced into both the civil and military establishments. Towards the close of the year 1783, the tranquillity of the island was seriously interrupted by an extensive mutiny among the soldiers, occasioned by a few trifling regulations respecting their punch horses, which appeared to them of an insulting and degrading tendency. After a slight skirmish, the insurgents were reduced, and the ringleaders executed. The mutinous disposition of the garrison was afterwards entirely suppressed, and the whole character of the troops highly improved, under the judicious management of Governor Brooke. The place became even a nursery of excellent recruits for the East Indies; and during his government, from 1788 to 1800, more than 12,000 soldiers were sent to India. The same gentleman made great additions to the defences on the heights, established a code of signals, built a new and safer wharf for the shipping, improved the regulations relative to the treatment of the slaves, gave encouragement to many useful suggestions for the improvement of agricultural operations, and, by his active enterprizes at the commencement of hostilities with the Dutch in 1795, rendered the little island of St Helena peculiarly serviceable to Great Britain. His successor Colonel Patton evinced a similar zeal and ability, in whatever concerned the welfare of the settlement. He particularly erected telegraphs, rendered the guns on the heights more efficacious for annoying an enemy, introduced the use of terra puzzolana in the formation of aqueducts, and applied his attention, by means of honorary rewards and religious instruction, to improve the character of the slaves. Many important agricultural improvements were introduced by Governor Beatson, and particularly the use of the plough in the tillage of the soil. In a volume of tracts relative to the island, he has minutely pointed out its various capabilities, and suggested divers plans for its better administration and culture. The greatest want under which the settlement labours is the scarcity of fuel, and coals have actually been carried thither from England. But the last mentioned writer maintains, that with ordinary care, the island might be made to produce in a few years a sufficiency of wood for its own consumption in fuel, and for all the other purposes of life.

The island of St Helena, when first seen at sea, presents the appearance of a naked and rugged rock, extremely abrupt at its northern extremity, but more shelving towards the south. Upon a nearer approach, the central eminences are perceived clothed with verdure, and towering to the clouds. Upon drawing still nearer, these are again shut out from the view, and nothing is beheld but a girdle of inaccessible precipices overhanging the ocean, some of them exhibiting the most fantastic shapes, and others rent down to their base, disclosing the most hideous chasms. These rocks are principally basaltic; and the strata are observed to lie in every possible variety of direction. The whole mass has every appearance of having been produced by a submarine volcano; or, what some consider more probable, being the summit of a great submarine mountain, which had formerly been a volcano. The sea around the coast is of an unfathomable depth, and vessels may pass within a cable's length of almost perpendicular cliffs 1600 feet in height. The only anchorage is in Chapel Valley bay on the north-west and leeward side of the island, where ships may lie in smooth water from 8 to 25 fathoms deep. The tide rises sometimes to the height of five feet; and the surf upon the shore, especially about the season of Christmas, is very tremendous. Many lives were lost in approaching and leaving the land in boats, till the new wharf was constructed by Governor Brooke in 1790; but there is only one instance of a shipwreck upon the island, which happened at the time of its discovery; and only one also of a vessel being windbound in the roads. The variation of the compass on the coast, in 1768, was 12° 47′ west; in 1777, 13° 15′; in 1796, 15° 47′ 30″; in 1802, 16° 30′. The principal inlets, by which the island can be approached, are James's Town, Rupert's Bay, Lemon Valley on the north-west side, and Sandy Bay on the south-east; all of them regularly and strongly fortified. There are likewise several ravines, where it may be possible, though with great difficulty, for individuals to effect an entrance; but even these are either protected by batteries, or easily defended by rolling stones from the heights. The island is 10½ miles at its greatest length, 6¾ in breadth, about 28 in circumference, and contains 30,000 acres on its surface. There are only two plains in the whole of this extent; the largest of which, at Longwood, comprises 1500 acres of fine land, sloping gently to the south-west.

St Helena is unequally divided by a lofty chain of hills, which runs in a curved direction nearly east and west, bending towards the south at each extremity; and from which alternate ridges and valleys branch off in various directions, but chiefly north and south. Towards the eastern termination of this chain is Diana's Peak, the highest point of land on the island rising nearly 2700 feet above the level of the sea. On the same ridge are Cuckold's Point, 2672 feet; and Halley's Mount, 2467. Nearer the coast, and overhanging the sea, are Flag-staff, 2272; and Barnscliff, 2015. In the centre of the island is the alarm house, 1960. High Knoll, to the southward of Ladder Hill, is 1903; and Longwood-house, the official country residence of the lieutenant-governor, is 1762 feet. On coming round to the north-west and leeward side of the island, James's Valley opens to the view. It is bounded by two rocky mountains, Rupert's on the east, and Ladder Hill on the west, which gradually recede from each other as they approach the coast, where they terminate abruptly in two stupendous and perpendicular cliffs. The space inclosed between these heights is of a triangular form, about a mile and a half in length, and 350 yards broad at its base, which faces the sea. In this confined spot is situated James's Town, which presents in its whole appearance, a peculiar combination of military strength and rural simplicity. A fortified line extends from cliff to cliff, fronting the anchorage, and covered with cannon, nearly level with the water's edge. After passing the draw-bridge, and advancing between a double row of Peepel trees, (a species of Indian banian,) you enter the town by an arched gate-way, under a rampart or terrace, which forms one side of a handsome parade, about 100 feet square. On the left side is the government-house, usually named the Castle, inclosed with a wall; and directly fronting the gate-way is the church, a plain but not inelegant structure. The principal street, containing about 28 houses, commences between the church and the Company's garden; and, in its progress, divides into two other streets, one on the east side leading into the country, and the other, which has a number of well furnished shops, proceeding towards the upper part of the valley, where the barracks, hospital, and new garden are situated. The houses, generally two stories high, are neatly built in the English style, and well white-washed. The town contains many little gardens, groves, and shaded walks, and extends the whole length of the valley, which gradually decreases in breadth, till at last there is room only for a single house. The view on each side, from the streets, is awfully sublime, and discovers enormous masses of rock impending over the valley, in a manner sufficiently alarming to the mind of a stranger. The roads which give access to the interior of the island, and which have been formed with incredible labour, by blowing up the rocks, are carried along the sides of Rupert's and Ladder Hill in a zig-zag direction; and the ascent to the summit is so easy, that oxen and carts pass along the apparently perpendicular precipice without difficulty or danger. For the space of two miles, nothing but naked sterility and a rocky wilderness meets the eye of the traveller; but the sight is soon gratified by the sudden prospect of woody heights, verdant lawns, cultivated plantations, and handsome little country seats. The summit of High Knoll, particularly, presents a beautiful series of such prospects, surrounded by a lofty ridge of hills and precipices, which completely close in the view, and finely contrast with the softer and richer scenes which they inclose. On the south side of the Knoll, about three miles from the town, is the governor's country residence, called Plantation House, a handsome and well-built edifice, erected in 1792. Its environs, by the combined efforts of nature and art, have been rendered the most beautiful spot in the island. Besides the indigenous productions of the place, the pine of the north, the mimosa of New South Wales, the coffee plant of Arabia, the banian and bamboo of India, the African aloe and prickly pear, the apple, peach and mulberry of Europe, with various other plants and trees, from the most opposite and distant climes, are to be found within the inclosures. Longwood, the country residence of the lieutenant-governor, on the opposite side of Ladder Hill, and also about three miles from the town, is situated on an elevated plain, or rather gently rising ground, on the summit of which is a flagstaff, from which the place takes its name. The adjoining space was once nearly covered with gum-wood trees, which, upon the opening of avenues among them, were gradually destroyed by the south-east wind; but young trees, which have been since planted, are thriving well, and the whole scenery bears a greater resemblance to that of England, than any other spot on the island. There are here about 1500 acres of good meadow land, of excellent soil, and capable, if supplied with water, of proving highly productive. From Sandy Bay, which is about an hour's ride from Plantation House, by a winding road along the declivities of little green hills, a still more romantic and beautiful scenery opens to the view, of which actual observers have given the most enraptured descriptions. "Though in general," says Mr Brooke, "a bird's eye view lies before the spectator, hills rise above him to an elevation much greater than the spot on which he stands. Those on the left, richly clothed with trees to the very summits, display a wonderful contrast to the wild and grotesque nakedness that triumphs on the right, where shelving cliffs, surmounted by huge perpendicular and spiral masses of rock, are multiplied under every shape and aspect. The downward view consists of a variety of ridges, eminences, and ravines, converging towards the sea into one common valley. Among this scenery are interspersed the dwellings of planters, the different forms of gardens and plantations, and the pasturing of cattle; the prospect closing with the distant sea, rushing in between two black craggy cliffs, which the surf whitens with its spray. The infinite diversity of tint that overspreads the whole of this extraordinary picture, the majesty of one part, the reposing beauty of another, and the horror of a third, cannot fail to delight and astonish every observer of nature." "One feels," says Mr Johnson, "as if transported into a new planet, where every object strikes by its novelty, and is altogether unlike any thing which he had ever before seen. All the surrounding hills, cliffs, rocks, and precipices, are strangely fashioned, and so fantastically mixed and blended, that they resemble more the aerial shapes which we see among the clouds, than any thing composed of denser materials." But it is from the summit of Diana's Peak, which is nearly in the centre of the island, that the most complete view of St Helena is brought under the eye. Nothing intercepts the horizon; and all the detached scenes and prospects are beheld at once, forming a picture inconceivably diversified, and full of the most interesting groups.

The climate of St Helena is remarkably temperate and salubrious, and peculiarly adapted to the constitution of Europeans. In James's town, the thermometer seldom rises above 80°; but, in calm weather, the heat reflected from the sides of the valley is frequently oppressive. In the country, the temperature is more mild and uniform; scarcely so hot, and never so cold, as in England. In some seasons, the highest point of the thermometer, during the summer, has been only 72° in the interior of the island; and the ordinary range of Fahrenheit's scale, during winter, is from 55° to 56°. The average temperature through the whole year is from 66° to 78° of Fahrenheit at James's Town; from 61° to 73° at the Plantation-house; and from 56° to 68° at Longwood. The rains also fall more equally through the whole year than in most tropical climates, but most abundantly in the month of February. In the vicinity of some of the higher points, especially of Diana's Peak, which, by being covered with trees, is supposed to attract the clouds, scarcely a day passes without a shower. Cloudy days are more numerous than those of clear scorching sunshine; a circumstance which has been remarked as propitious to the growth of trees and pasturage, but unfavourable to the ripening of European fruits. Thunder and lightning are scarcely ever experienced; and the atmosphere is generally so clear, that a ship may be descried at the distance of 60 miles.

The soil is of a clayey nature, and well suited both for European and Indian productions. It is in many places of considerable depth, and always most productive in spots which are most elevated and farthest removed from the sea. Even on the summits of the interior hills, the grass is often so luxuriant as to reach the knees of the oxen. Clear and wholesome springs issue from the sides of almost every height; but they form only very inconsiderable rills. A few of these, especially those at Fisher's Valley and the Briars, are not observably diminished in dry weather; but, in general, they are wholly dependant on the rains, or the clouds, which are almost perpetually in contact with the tops of the mountains.

Iron ore has been found in some parts of the island; but the scarcity of fuel prevents it from being brought to the furnace. Appearances of gold and copper have been observed, and some stones capable of taking a beautiful polish. Limestone is plentiful; and some of it, a concretion of sand and shells, is of an excellent quality; but the cement used in ordinary buildings is mud or earth, which is found to answer the purpose extremely well, perhaps from its containing a mixture of terra puzzolana. This last mentioned substance, which abounds on the island, forms, in conjunction with lime, a cement remarkably retentive of water, and acquiring, from the contact of that fluid, the solidity of rock: hence it is much used in the construction of aqueducts.

The summits and sides of the interior hills are covered with furze, of which the seed was brought from England, and with various indigenous trees and shrubs. Of these, the most abundant used to be the gum-wood, of which there are three kinds, all evergreens, the common, the bastard, and the dwarf gum-tree. The last is generally called *scrub-wood*, and seldom grows higher than three feet; but the common kind has a tolerably straight stem from 20 to 30 feet in height, and throws out its branches and leaves in the form of an umbrella. The bastard species has less of the gummy texture, and is farther distinguished by having a smooth leaf, and bearing its blossoms in small bunches. All the kinds contain a highly aromatic gum, which renders the wood extremely pleasant as fuel, for which purpose it is chiefly calculated, though not altogether unfit for building, if protected from the weather. From the trunks of the common and bastard species, a sweet-flavoured liquor, called by the natives *toddy*, issues spontaneously; and a bottle, so placed as to catch the natural exudation, may be filled in the course of a night. Of the other native trees may be mentioned, string-wood, dog-wood, red-wood, or ebony, and the cabbage-tree, of which the two last are very durable, and much valued in building. Oaks, cypress, and pinaster, have been introduced into the plantations, and thrive well. The first, particularly, grows up very quickly, but decays with equal rapidity, though the wood, when cut in a sound state, is said to be of a very close grain and firm texture. The ferns of St Helena are very numerous and beautiful; and one species, called the *tree-fern*, grows to the height of 14 or even 20 feet, with leaves five feet in length. The myrtle, to which the climate is peculiarly adapted, grows to the height of 30 feet, and the cotton plant thrives very readily. A shrub, which the natives call *samphire*, but supposed to be the barilla, grows spontaneously on the thin crust of soil generally found near the sea, and yields from its ashes a large quantity of the marine alkali for the manufactories of soap. The English vernal grass prevails in the higher parts; but, in the low grounds, the wire-grass, or droop, is more abundant. This last is sweet and nutritious, and suffers less than the other sorts from hot or dry weather; but, instead of it, a coarse herb, called *cow-grass*, originally from the Cape of Good Hope, has been introduced into many of the pastures. Lucerne has succeeded in some situations, and is considered as well calculated for general cultivation.

Fruits, in general, ripen best in the vallies near the coast; but almost on every farm are produced vines, figs, limes, oranges, lemons, citrons, guavas, bananas, peaches, quinces, pomegranates, tamarinds, mulberries, melons, water-melons, and pumpkins. Mangos, cocoa-nuts, sugar-cane, pine-apples, and strawberries, are also raised in the island, but only in small quantities. Apples have not succeeded generally; but one orchard, particularly, about three acres in extent, has been known, besides other fruits, to yield in one season 24,000 apples of a large size. Cherries have been tried, but without success. Gooseberry and currant bushes when planted, become evergreens, and yield no fruit; but the common blackberry, which was introduced in the year 1780, has found the soil and climate so congenial, that it has completely overspread large tracts of ground; and, as the only remedy against its encroachments, a public order was issued, and has uniformly been in force, for its entire extirpation. A species of yam, originally imported from Madagascar, is commonly cultivated in the vallies; but it requires almost continued moisture for fifteen months to bring it to perfection. During the last twenty years, however, the culture of the potatoe has more profitably occupied the attention of the farmer; and three successive crops of this valuable root are frequently produced in one season. Cabbage, peas, beans, and other garden vegetables, are raised every where in great abundance. Attempts have more than once been made to introduce the cultivation of wheat, barley, and oats; but probably from drought, or some unknown peculiarity in the soil or climate, the experiment did not succeed. It is more from this failure, than from the alleged voracity of the rats and mice, that grain is not raised. Indeed, as the principal value of the island consists in its being a place of rendezvous and refreshment for the homeward bound ships from India, the cultivation of grain has been deemed of less importance, and less anxiously encouraged, than the rearing of live stock, and the production of wholesome vegetables.

The breed of cattle and sheep on the island is originally English; but, in consequence of the large demands from the India ships, the stock is very scanty; and the inhabitants during the greater part of the year subsist upon rice and salt provisions, issued below prime cost from the Company's stores. Goats are numerous, and their flesh well tasted; but pork, except what is reared by the more opulent inhabitants, is of a very inferior quality, as the animals are chiefly fed with the heads and offals of the coarser kinds of fish. Rabbits abound in some spots. Rats and mice are amazingly numerous, and frequently very destructive. In 1756, they are said to have barked the trees at Longwood for food; and in 1700 actually devoured one another, so as almost to clear the island of the whole tribe. With a little ordinary care, however, Governor Beatson cleared his farms and gardens of vermin, as completely as could have been done in England.

The canary bird abounds in the island; and the Java sparrow is a great annoyance to the farmers. Red linnets are also numerous; and are observed to build two nests, in the uppermost of which the male bird takes his station, and serenades the female with his song during her incubation. Pheasants and partridges, in consequence of their having been protected by government, have become numerous; but the guinea-fowl, with which the island was formerly well stocked, are now seldom to be seen. The shores abound with sea-fowl, which deposit their eggs among the cliffs; and these, which are collected in the months of October and November, greatly resemble in flavour those of a plover. One species of these sea-birds make their nests in the more central and woody eminences, whither they are often seen flying across the country with fish in their bills.

More than seventy kinds of fish are found on the coast; but those which are commonly caught are, mackerel, albicore, cavalloes, jacks, congers, soldiers, old-wives, bull's-eyes, &c. The coal-fish, from two to three feet in length, are singularly delicate and high flavoured; but seldom more than eight or ten of them are taken in the course of a year. The flying-fish, when pursued by their various enemies, often drop upon the rocks; and some have been picked up, measuring more than two feet in length. Whales are frequently seen in the vicinity of the island; and have sometimes been killed in the roads by the south-sea whalers. Turtle frequent the coast in the months of December and March, and are often taken by the fishing boats. Shell-fish are not uncommon, especially one species resembling lobster; and rock oysters are found in some situations in a solid mass, which may be separated into distinct fish.

The whole superficial extent of St Helena is calculated at 30,000 acres, of which the greater part is a barren waste

About 8000 acres have been brought into cultivation; and much more might be improved as pasture-ground, if water were conveyed to it, which in many situations is perfectly practicable. Of the cultivated portions, about 1500 acres are in the occupation of the governor, the lieutenant governor, and the Company; 4000, besides goat-ranges, have at different times been let in leases at a low rent, seldom exceeding 16s. per acre; and about 2300 have become free by original grants to settlers. In no country is farming a more profitable employment than at St Helena, when droughts and other causes do not occasion a failure in the crops. The richest lands produce three crops of potatoes in the year, amounting in all to 400 bushels per acre, which will sell at 8s. per bushel. The price of labour, however, is high. The wages of a carpenter are 6s. or 7s. a day; of a mason, 4s. or 5s.; of a common labourer 2s. or 2s. 6d. A black servant may be hired from 10*l.* to 20*l.* per annum; but must in addition be supplied with clothing, maintenance, and medical attendance in case of sickness. The price of a slave of good character, and acquainted with husbandry work, is 150*l.*; but others of inferior qualifications may be procured for 30*l.* Even with all these expences of cultivation, the lands in general are estimated to yield a profit of seven or eight per cent.; and, if wisely improved, as supposed by Governor Beatson, to be capable of affording an inexhaustible supply of fresh provisions and vegetables for the trade of the southern and eastern world. The use of the plough, drawn by oxen, so recently introduced by this officer, may tend to diminish the expences of the farmer; but only 2000 acres are said to be capable of being tilled in this manner, of which not more than 68 have been brought under cultivation. As the roads are in general inaccessible to carts, particularly in the inland districts, the produce of the farms in the country is carried on men's heads, occasioning a great waste of labour. Asses, however, have lately become an object of attention, as suited for this service; and their price has risen from 5*l.* to 25*l.* They are well adapted to the island, as they prefer those vegetables which the other animals refuse to eat.

By repeated charters from the crown of Great Britain, the island of St Helena is assigned to the East India Company as perpetual proprietors, with all the powers of sovereignty and legislation. The supreme authority on the island is vested in the governor and a council. The council is composed of the lieutenant-governor, and senior civil servant, with the addition occasionally of a fourth and sometimes a fifth member, as the Court of Directors may judge proper. These represent the lords proprietors, superintend all the concerns of the island, act as justices of the peace, and exercise the ordinary jurisdiction of the ecclesiastical court. When the council is not assembled, the whole authority of the board centres in the governor, who may also exercise, as occasion requires, all the powers of Captain-General. The civil establishment consists of an accountant, pay-master, store-keeper, and the secretary to government, with their assistants, some of whom are at the head of inferior departments, and among whom promotion takes place according to seniority. The ordinary military force is composed of a corps of artillery, commanded by a lieutenant-colonel, a regiment of infantry, and five companies of white and black militia, who are at times rather on the footing of volunteers. There are also a head surgeon, an engineer, and a chaplain.

The whole island forms only one parish, but is divided into three districts, the East, West, and South or Sandy Bay divisions. There are two churches, one in the town, and the other in the country; and the ministers of religion in the settlement have, of late years, been as highly distinguished for the excellence of their character, as, in the earlier period of its history, they were noted for their incompetency and profligacy.

The civil and military establishments cost at an average 40.000*l.* per annum;* and there is generally an additional expenditure of 10,000*l.* on the head of contingencies. The only revenue of the Company is derived from the rents of their lands, which may amount to about 1100*l.* but gradually increasing as the old leases expire; and from the profits of a monopoly of arrack, which are estimated at 6000*l.* But they have a dead capital of 200,000*l.* sunk in public works, naval and military stores, &c.; and also warehouses for all kinds of articles useful to the natives or the shipping, which, though sold at a profit of ten per cent. do not cover the expences. But the best returns from the island must be sought in the accommodation which it affords to the Company's shipping, and the security which it provides for their commerce, against the hazards of the sea, and the attacks of an enemy. Its water,† climate, and vegetable productions, are so excellently adapted, particularly for scorbutic diseases, that many who have been sent to the hospital in the last stage of the scurvy, have, in the space of two weeks, been restored to perfect health. It is generally acknowledged, however, that the spirit of monopoly renders all the necessaries of life immoderately expensive, especially to strangers; and that a more abundant supply of fruits and vegetables might be provided for the vessels which arrive in the roads, if it were not that the persons who raise these articles for sale prefer a high price to a large disposable crop; and would rather, it is affirmed, allow them to rot, than sell them at a lower rate. Fresh beef, which, by a regulation of the government, is fixed at a certain rate, (of late years about 6d. or 6½d. per pound,) is the only kind of provisions which can be procured at a moderate price. Other articles of food, in the year 1805, were purchased at the following prices, which vary, however, considerably, according to the demand.

Strangers residing in the town can be accommodated in private houses, at the rate of thirty shillings, or one guinea a day, with an excellent table, good wines, and comfortable lodgings.

By the registered returns for the year 1805, the population of St Helena, exclusive of the garrison and Company's civil establishment, amounted to 2064, of which number 504 were white inhabitants, and 1560 blacks: Of the latter,

* The late additions to the officers and garrison, in consequence of Bonaparte's residence on the island, are said to have raised the annual expences of the settlement to 300,000*l.*

† The water is excellent and abundant, and can now be conveyed so easily into the boats by pipes, that a fleet has been known to take on board 2000 tons in less than three days.

329 were free. In 1814, the whole population, including the garrison, which ought always to be about one thousand men, was estimated at 4000 souls. Upon an average of five years, from 1801 to 1805 inclusive, 165 ships touched annually at the island; and in time of war, when fleets are detained for convoy, the crews and passengers frequently equal the whole amount of the population. No strangers are permitted to settle on the island, without permission from the East India Company. It has been recommended to allow the soldiers, whose time of service may have expired, to remain as husbandmen; and to import Chinese labourers, who might be bound to serve the Company in the first instance, but permitted to hire themselves to others when not required to work for government. No importation of slaves has been allowed for a long time; and those who belong to the island, being generally treated with much kindness, are rather increasing in number. The inhabitants are in general a robust and healthy race, but rarely attain to a great age. The diseases to which they are subject, are principally of a catarrhal nature; and yet it has been observed that the driest seasons are frequently the most unhealthy. The inhabitants of the town retire to their farms and gardens during the greater part of the year; but, upon the arrival of the homeward bound India fleets, they flock with alacrity to the town, open their houses for the accommodation of the passengers, and entertain their guests with plays, dances, and concerts. They are a worthy, humane, and cheerful race, of people, superficially accomplished, and sufficiently fond of gaiety. The young women are described as very smart and agreeable in their manners. They are bold and expert riders, galloping up and down the most formidable precipices. Their complexions are fine, and they are said to be very successful in procuring hasty matches among those who touch at the island, on their return from India. Most of the settlers, more recently arrived from Europe, employ their capital rather in mercantile than in agricultural concerns; and considerable gains are made among them by the sale of European articles to the India fleets.

This extraordinary spot of ground, independent of its political and commercial advantages, may justly be regarded as a most interesting natural curiosity, and, notwithstanding all that has been written respecting it, there is still wanting a scientific survey, and accurate classification of its natural history. But it has recently become a peculiar object of curiosity to the nations of Europe, in consequence of its having been selected as the prison of Napoleon Bonaparte; and as there appears to be but one opinion as to the justice and policy of his detention, the principal point of enquiry generally relates to its adaptation for the security of his person. In addition to the almost inaccessible ramparts with which it has been provided by nature, its eminences are covered with telegraphs and watch towers, and its various fortifications defended by nearly 500 pieces of cannon, so that, with ordinary vigilance and a competent garrison, it may be pronounced impregnable by any external force. But though a rescue may be next to impossible, an escape is not accounted impracticable. There are various points on the coast, where one or two individuals, with a certain degree of naval assistance from without, (which the multitude of fishing boats and ordinarily favourable state of the weather must tend to facilitate,) may, without much difficulty, leave the island; and instances have occurred to prove, that, even in an open boat, a run might be accomplished, with little hazard, to the island of Ascension, or even to the coast of Brazil. See Lord Valentia's *Travels*, vol. i. Forbes's *Oriental Memoirs*. Campbell's *Travels in Africa*. Brooke's *History of the Island of St Helena*. Johnson's *Account of St Helena*. Beatson's *Tracts relative to the Island of St Helena*. (*q*)

HELIACAL, is a term derived from ἡλιος, *the sun*, and applied to the rising and setting of the heavenly bodies. A star is said to *rise heliacally*, when, after having been in conjunction with the sun, it gets to such a distance from that luminary as to become visible in the morning before sun-rise. A star is said to *set heliacally*, when it approaches so near to the sun that it can no longer be seen in the evening after sun-set.

HELICON, is the ancient name of a mountain in Bœotia, near the Gulf of Corinth, sacred to Apollo and the Muses, who thence received the name of Heliconides. Its modern name is *Sagara*, pronounced *Sacra*, an obvious corruption, as Dr Clarke has stated, of *Ascra*, a town upon Helicon, and the birth-place of Hesiod. Dr Clarke, who visited this mountain, has favoured the public with a very interesting description of it. Instead of proceeding to Lebadea, by the usual circuitous route along the level country, he ascended the mountain from Neocorio, passed by the monastery of St Nicholo to Sagara, and afterwards descended by the monastery of St George to Lebadea. He ascended in a north-west direction above the village of Neocorio, and passed a chapel in ruins. On his right hand, there was a rivulet flowing from Helicon towards the plain of Neocorio, or Thespia; and beyond this, on the opposite side of the dingle through which this rivulet fell, he saw from an eminence a village called Panaja. After travelling along the north-east side of the mountain, he reached in about an hour the little monastery of St Nicholo, situated within a sheltered recess of Helicon. The mountain surrounded it on all sides, a ruined tower belonging to Panaja appearing in front through a small opening. The aromatic plants filled the air with their spicy odours. A perennial fountain threw its limpid waters into the rivulet below; and the monastery was almost concealed amid trees, no less remarkable for their variety than for their beauty and luxuriance. The fountain was covered with moss and with creeping plants, forming a pendant foliage over all the fabric constructed around it. In a church near the monastery, Dr Clarke found a long inscription on the shaft of one of the pillars, distinctly mentioning that the ΜΟΥΣΕΙΑ, or games sacred to the Muses, according to Pausanias, were celebrated near a grove upon Mount Helicon. This inscription, and other evidence, convinced Dr Clarke that he had now discovered the fountain Aganippe, and the Grove of the Muses. Hence it followed, that the rivulet below was the Permessus, parent of Aganippe, called Termessus by Pausanias, and flowing, as he describes it, in a circuitous course from Mount Helicon.

A path winding through the grove, conducts from the monastery to the spot where, upon the left hand, the water gushes forth in a clear and continued stream. "The work about the fountain," says Dr Clarke, "was until lately very ancient, and not long ago there was an antique cistern in front of it; but the present monks, finding the work in a ruined state, undertook to repair it, and thus destroyed much of its original and venerable appearance. In its state of restoration, however, it is not without picturesque beauty; for they have merely erected an arcade of stone, whence the water issues, and this is already adorned by moss and creeping plants. The walks about the fountain, winding into the deep solitude of Helicon, are in the highest degree beautiful. All above is grand and striking, and every declivity of the mountain is covered with luxuriant shrubs, or tenanted by browzing flocks. Higher up the mountain, at the distance of two miles and a half from this grove and from the fountain Aganippe, was the fountain Hippocrene, fabled to have sprung from the earth when struck by the hoof of Pegasus."

From the Grove of the Muses, Dr Clarke descended to the Permessus, and crossing that rivulet, he ascended in a north-west direction towards the higher parts of Helicon. Wherever the surface was laid bare, he found the rocks to consist of primary limestone. By proceeding with difficulty along a craggy narrow path, he reached the heights of Sagara, where he observed part of the ancient paved causeway, which formerly led from Thespia to Ascra and to Lebadea. From this point, which was two hours journey from Neocorio, the whole of Bœotia was seen. The road now extended south-east and north-west, and another hour was necessary to descend into the deep valley in which Sagara is situated. This valley is entirely surrounded by high rocks, and by the towering summits of Helicon. A level plain is seen below, having its woods and cornfields almost buried in the deep bosom of the mountain. A steep and rugged descent now conducted Dr Clarke to the village of Zagara, which is divided into two parts by a river flowing across this valley, one part of the village being high above the other. The lower part stretches into the level plain; and above the upper part a small white edifice, the monastery of Panaja, appears embosomed among trees. Dr Clarke has shewn, we think very satisfactorily, that this village is the Ascra of the ancients, the place of Hesiod's nativity.

After passing Zagara, Dr Clarke advanced among the boldest rocks, and ascending by a narrow, steep, and stony path, he reached the highest part of this road over Helicon, "commanding a prospect," as he remarks, "which, in the grandeur of its objects, and in all the affecting circumstances of history thereby suggested, cannot be equalled in the whole world. The eye ranges over all the plains of Lebadea, Chæronea, and Orchomenus, looking down upon the numerous villages now occupying the sites of those and of other illustrious cities. From the spot where the spectator is placed, the most amazing undulations of mountain scenery descends in vast waves, like the swellings of an ocean, towards Parnassus, whose snowy bosom, dazzling by its brightness, was expanded before us with incomparable grandeur."

After passing another fountain, and travelling a quarter of a mile over an ancient paved way, Dr Clarke reached a magnificent terrace, elevated as it were above all Greece, and continuing to descend, the monastery of St George appeared in view, bearing north and by west. He then arrived at the village of Kotumala, about 1¾ hour from Zagara, and commanding the most sublime views. After passing the remains of an aqueduct, and the ruins of a city upon a hill, he reached Panori, two hours distant from Kotumala. He then passed two bridges, and came in sight of Lebadea, which will be described under that article.

We have thus given our readers a very brief account of Dr Clarke's most interesting examination of the antiquities of Mount Helicon. They will naturally turn to the original work for an ampler account of his journey. The classical reader will feel himself inspired at every step, and will share the fine sentiments which the sight of ancient Greece awakened in the first of modern poets.

> Where'er we tread, 'tis haunted holy ground;
> No earth of thine is lost in vulgar mould;
> But one vast realm of wonder spreads around,
> And all the muses' tales seem truly told,
> Till the sense aches with gazing to behold
> The scenes our earliest dreams have dwelt upon;
> Each hill and dale, each deepening glen and wold,
> Defies the power which crushed thy temples gone:
> Age shakes Athenia's power, but spares gray Marathon.
> Long to the remnants of thy splendour past,
> Shall pilgrims pensive but unwearied throng;
> Long shall the voyager, with the Ionian blast,
> Hail the bright clime of battle and of song;
> Long shall thine annals and immortal tongue
> Fill with thy fame the youth of many a shore;
> Boast of the aged! Lesson of the young!
> Which sages venerate, and bards adore,
> As Pallas and the Muse unveil their awful lore.
>
> Byron's *Childe Harold*, Canto II.

See Clarke's *Travels*, Part ii. Sect. iii. p. 92—118.

HELIGOLAND, or Helgoland, is a small group of islands belonging to Great Britain, and situated opposite the mouths of the Elbe and the Weser, and at the distance of nine German miles from each. The islands of Heligoland consist, 1st, of the island of Heligoland; 2d, the Sandy Island, called the Downs; and 3d, of several reefs and rocks, of which that called the Monk is the most remarkable. The island of Heligoland is divided into the High Land or the Cliff, and the Low Land. It is said to be in a state of rapid destruction from the encroachments of the sea; and it is reported among the inhabitants, that during the last century, it has been reduced from 11 miles in length to its present dimensions of 1 mile. The high land or cliff, according to the measures taken by Dr Heinemeyer, is 166 feet at its greatest, and 88 feet at its least height, and has a circumference of 4200 paces. It is ascended by a flight of 203 steps. The low land, which increases sensibly every year, is connected with the eastern part of the cliff by a rock about 500 paces long. The circumference of the low ground was 1400 paces in 1800. The circumference of the whole island, including the high and low ground, is 4600 paces. The Downs, or Sandy Island, is about two-fifths of the size of Heligoland; but its extent is constantly varying.

According to Dr Macculloch, Heligoland consists of strata of indurated clay alternating with beds of gray limestone, forming an angle of 30° with the horizon, and dipping to the north-east. The clay is of a strong red colour, and contains much oxide of iron, and some carbonate of lime. The limestone is in some parts formed of various marine remains, and in others it is uniformly granular. Through both these are dispersed in various places deposits of copper ore in small quantities. These consist of carbonate of copper diffused through the earthy matter, and of crystallized masses of the same substance; and more rarely there are found lumps of red oxide, mixed with particles of gray ore and native copper. The beach is covered with various siliceous pebbles, containing grains of the same substance imbedded in them, together with variously coloured porphyries and hornstones. On the shore are found belemnites, and other calcareous and flinty fossil remains; and considerable quantities of pyrites, and carbonized and pyritaceous wood, are contained in the clay strata.

This island is said to have suffered great physical revolutions in the years 800, 1300, and 1500. The Downs, or the Sandy Island, was not only connected with the low ground of Heligoland, but even a part of the reefs was covered with earth. Other revolutions took place in 1649 and 1720. Before the first of these epochs, the low land of Heligoland contained the isle called the Downs; and even before 1720, there existed between the two islands a narrow isthmus, which was seldom covered with water, except during very extraordinary tides. Since 1720, the two islands have been separated by a strait called Waal, which is from 18 to 20 feet deep.

The soil which covers the rock is from 3½ to 4 feet deep, and is rather fat than sandy. It produces annually about 300 tons of barley, and a little oats. The uplands afford good pasture for about 60 cows, and 400 or 500 sheep. In the north-west part of the island there are three ponds of rain water, called *safiskulen* by the inhabitants. The water of the two springs in the low ground is fit only for cattle, and is scarcely of use for washing. The principal revenue of the island is derived from the fish which are caught. About 120,000 Lubeck marc of fish, amounting to about 230,000 francs, are exported annually.

There are two good harbours in the island, which could be improved at a trifling expence. The northern harbour, where the larger vessels of the islanders lie, varies in depth from 7 to 42 feet at half-tide, and the southern harbour, which receives the chaloupes, has a depth of from 10 to 24 feet. To the east of the Downs is a road, which has 48 feet of water. The tides ordinarily rise 9 feet, but with a north-west wind they rise to a great height.

The island was defended in 1800 by four batteries, that of the south-east, that of the south, and the high and low battery on the north. The two first were directed to the landing place for large vessels, and the other two against the current between the islands. They mounted 19 cannon, and 4 howitzers, with 56 regular troops. The light-house serves to direct all vessels that wish to enter the Hever, the Eyder, the Elbe, the Weser, and the Jade.

There are no fewer than 342 houses on the high ground, and 78 on the low ground, making in all 420. The church, the magazine, and the public buildings, are erected on the high ground. Those on the low ground are merely the huts of the fishermen. A building has been erected on the sandy island, for the accommodation of those who may be shipwrecked upon it. The population was 2200 in the year 1800. In the same year there were 11 sniggs (small vessels) on the island, 97 chaloupes, and 80 yoles.

The natives of Heligoland are descended from the Frisians, and have preserved their language and their principal customs. They are chiefly employed in fishing and piloting vessels up the Elbe, the Weser, and the Eyder. They live in huts, and lie upon planks placed one above another, though some of the houses on the high ground are clean and well furnished. The women plough and sow the ground, thrash the grain, and grind it for food. They have neither carts nor horses. They obtain from Nordhovet in Eyderstedt, forage for their cattle in winter, and their fuel is got from the ports on the Elbe.

This island is supposed by Malthe Brun to be the Alokiai islands of Ptolemy. It appears also to have been the *Fosetisland*, *Fosteland*, or *Phosteland*, which appears in the history of the 7th, 8th, and 9th centuries to have been the seat of a peculiar worship paid to the idol *Fosetes*, who is supposed by some to be the Vesta, or Festa, of the Romans, and the Hertha of the Scandinavians. The altars of this deity were, however, overturned in A. D. 866, and his temple changed into a monastery. In 1403 and 1417, two famous pirates endeavoured to establish themselves on this island, in consequence of which it was put into a state of defence in 1539. The town of Hamburgh was afterwards anxious to obtain possession of it, but the Dukes of Holstein and Gottorp claimed with success this ancient dependency of Denmark, and it passed with the duchy of Sleswick into the possession of the Danes in 1714. The Danish government, however, neglected the great advantages of this position, and did not put it into a state of defence till the canal of Holstein was opened.

In September 1807, a small English squadron under Admiral Russel blockaded the island, which surrendered a few days afterwards, for the want of provisions. Thirty-two pieces of cannon, besides field-pieces and mortars, and a large stock of ammunition, were found on the island. By the arrangements in the treaties of Paris in 1814 and 1815, Heligoland has been transferred to Great Britain. East Long. of the light-house 7° 53′ 13″, North Lat. 54° 11′ 39″. See Malthe Brun's *Annales des Voyages*; Carr's *Northern Summer*; and the *Geological Transactions*, vol. i. p. 322.

HELIOCENTRIC. See Astronomy.

HELIOGABULUS. See Rome.

HELIOMETER from ηλιος the *sun*, and μετρειν to *measure*, is the name given by M. Bouguer, in 1747, to an instrument for measuring the diameters of the sun and moon. It differs in no respect from the divided object glass micrometer, which had been previously invented by Mr Savary, excepting that in the heliometer two whole object glasses were used instead of two semilenses. The object glasses are separated by a screw, as in Savary's instrument. See the *Memoirs of the Academy of Sciences* 1748, and our article Astronomy, vol. ii. part ii. A new heliometer, in which the semilenses are fixed at a certain distance, and the variation of the angle produced optically, is described in Brewster's *Treatise on New Philosophical Instruments*, p. 31. and 173. See also Micrometer.

HELIOPOLIS, from ηλιος, and πολις, *the city of the sun*, is one of the most ancient cities in the world of which any vestiges can now be traced. The most enlightened philosophers of Greece and Rome were attracted to this celebrated seat of learning. It was here that Herodotus became acquainted with the sciences and mysteries of Egypt. Plato was here taught philosophy, and about 30 years before Christ its ruins were visited and described by Strabo.

Strabo describes Heliopolis as built upon an artificial mount of earth, so as to be out of the reach of the inundation of the Nile; but owing to the accretion of soil from the annual inundations of that river, the place where it stood is now a perfect plane. In this city was erected a temple to the sun, where a particular part was appropriated for the feeding of the sacred ox, which was here worshipped under the name of Mnevis. There was also another splendid temple, with avenues of sphinxes and superb obelisks before the principal entrance. Out of the four obelisks which were erected here by Sochis, two were carried to Rome, one was destroyed by the Arabs, and the fourth still remains.

When Pococke visited Heliopolis, he observed the fragments of sphinxes still remaining in the ancient way leading to the eminence on which the temple of the sun stood. The sphinxes are, however, no longer visible. They are no doubt covered with the soil deposited by the Nile; and we agree with Dr Clarke in thinking, that not only the sphinxes, but even the pavement of the temple, might be disclosed by a very trifling excavation.

The obelisk or pillar of On, which is now the only piece of antiquity that marks the site of Heliopolis, is about 68 feet high, and 6½ feet wide on each side. According to Dr Clarke, who has given a very correct engraving of it, it is one entire mass of reddish granite. Each of its four sides exhibits the same characters, and in the same order. Those which face the south have been the least affected by the decomposition of the substance in which they are hewn; and it is from the southern side that Dr Clarke's engraving is taken. For a particular account of this obelisk, and the hieroglyphics which it contains, the reader is referred to Kircher *Syntagma* VIII. *Theat. Hieroglyph Oedipi Egyptiaci*, tom. iv. p. 330; Pococke's *Description of the East*, vol. i. p. 23; Shaw's *Travels*; Norden's *Travels*; but particularly Dr Clarke's *Travels*, part. ii. sect. ii. p 98.

HELIOSTATE, or Heliostata, from ηλιος the sun, and ιστημι I *stand*, is the name of a very ingenious and useful instrument, invented by Dr s'Gravesande, who was professor of mathematics at Leyden. The object of it is to give such a motion, by means of clockwork, to a polished mirror, that the beam of the sun which it reflects may be fixed, or remain in the same position during the diurnal motion of the earth. Hence it is of great use in all optical experiments, in which it is required to transmit the solar rays into a dark room.

The heliostate, which is represented in Plate CCXC. Fig. 1. consists of two principal parts; 1st, A plane metallic speculum, supported by a stand; and 2d, A clock for giving motion to the speculum. The speculum S, contained in a wooden frame, is placed in the brass case *a*, *a*, and is suspended by the handle AA, so as to have a free motion round an axis *a a*, which should pass along the surface of the speculum. The handle AA is joined to the cylinder C, whose axis is coincident with the middle part of the axis *a a* of the speculum. The axis of the tail DF, joined perpendicularly to the back of the speculum, is directed to the same point. This tail is made of a cylindrical brass wire, about the sixth part of an inch in diameter. The cylinder C is put upon the wooden stand P, the upper part of which is shewn separately in Fig. 2. The smooth iron cylinder *e* goes into a cavity in the copper cylinder C, so that, by the motion of the tail DE, the position of the speculum may be altered at pleasure. The wooden stand P is raised and depressed by the three brass screws B, B, B, turned with a key, and moving in a plate of brass.

The clock is represented at H, with an index which revolves once in 24 hours. The plane of the clock is inclined to the horizon, at an angle equal to the co-latitude of the place. The copper pillar FG, which supports the clock, consists of two parts, joined by the screws *d*, *d*, between which, as in a sheath, is moved an iron plate, in the middle of which there is a slit through which these screws pass. This plate is fixed to the lower plate of the clock itself, so that it can be raised and depressed, and fastened at any height by the screws *d*, *d*. The same effect may also be produced by the screws I, I, I, passing through the copper plates L, L, M. The extremities *b c*, *b' c'* must be in the same straight line, and a vertical plane passing through them must be perpendicular to the horizontal lines drawn on the plane of the clock, such as *fg*, *hi*.

When the plane of the clock is inclined at an angle equal to the co-latitude of the place, the plane LLM must be brought into a horizontal position by the plummet Q, the point of which is made to coincide with a point *o* marked on the foot M. But if it were required to use the instrument in another latitude, another point *o*, would require to be marked; and it would be necessary to incline the plane LLM to the horizon. The axis of the wheel which moves the index has a cylindrical perforation, but a little narrower below than above. The index, shewn separately at ON, in Fig. 3. is made of brass, and has a tail *pq* exactly filling the above mentioned perforation, into which it is thrust tight, so as to stick and be carried along by the wheel. The tail *p q* has also a cylindrical hole, through which passes the small brass wire *l k*, which remains in any position into which it is put. At the end *o* of the index there is a small cylinder *n* perforated cylindrically. The length of the index *n n'* was six inches in s'Gravesande's machine.

The iron tail *t* (Fig. 4.) of the piece T goes into the cavity *n*, Fig. 3. as shewn in Fig. 1. and moves in it freely, though not loosely. The small pipe R, Fig. 5. through which the tail DE of the speculum may be moved freely, may be suspended at different heights between the legs of the piece T (Fig. 4.) by the screw *r r* going into the parts *m m* of the pipe. The pipe can then turn freely round *mm* as an axis.

In order to fix the machine, another part, called the *placer*, must be used. The cylinder and the speculum being removed from the stand P, the brass pillar VX (Fig. 6.) is stuck tight upon *e*, Fig. 2. The ruler YZ moves round a centre at X, so as to remain in any position in which it is placed. The arm XZ has a peculiar construction and a certain length, but the length of XY is determined at pleasure. The end X*y* of the ruler, which does not extend beyond *y*, is included between other two, viz. *x* Z, and are on the opposite side. They are joined at Z, and are kept together by the screws *z*, *z*, which pass through a slit in the enclosed ruler X *y*. On this ruler is marked the small line *v s*, whose length is equal to $\frac{9}{100}$ parts of the length of the index. The arm XZ is equal to the length of the index, reckoning from the centre of motion at X to the end Z, when *x* coincides with *v*, where the divisions on *v s* commence. The line *v s*, which is unequally divided, serves to determine the length of the arm XZ for different times of the year, by bringing *x* to the division corresponding to the given day when the machine is used.

In order to mark the divisions, the arm is supposed to be divided into 1000 parts, hence *v s* will be 90 parts. The distances corresponding to the different times of the year are set down in the following table.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 21st March. | 1st March. | 21st Feb. | 11th Feb. | 1st Feb. | 21st Jan. | 11th Jan. | 21st Dec. |
| 21st Sept. | 11th Oct. | 21st Oct. | 1st Nov. | 11th Nov. | 21st Nov. | 1st Dec. | 21st Dec. |
| Parts. | Parts. | Parts. | Parts. | Parts. | Parts. | Parts. | Parts. |
| 0 | 8 | 17 | 32 | 47 | 64 | 77 | 90 |

On the opposite side of the ruler is drawn another line corresponding to *v s*, the divisions for which are given in the following Table.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 21st March. | 11th April. | 21st April. | 1st May. | 11th May. | 21st May. | 1st June. | 21st June. |
| 21st Sept. | 1st Sept. | 21st Aug. | 11t Aug. | 1st Aug. | 21st July. | 11th July. | 21st June. |
| Parts. | Parts. | Parts. | Parts. | Parts. | Parts. | Parts. | Parts. |
| 0 | 11 | 22 | 36 | 51 | 66 | 79 | 90 |

The instrument being thus constructed, is used in the following manner. Having adjusted the point $x$ of the placer to the division for the day of the month, place XV upon the stand P, (Plate CCXC. Fig. 1.) and put the ruler Y into the position and direction in which it is wished to fix the solar ray. The lines $bc$, $b'c'$ are placed in a meridian line drawn on the plane, and the point of the plummet Q is brought to $o$. The index NO is then turned till the sun's rays pass directly through the pipe R, which may be varied in its position till this is effected. The brass wire $lk$ is then raised or depressed, till the shadow of the end of it $l$ passes through the middle of the pipe R. This part of the machine is then moved to the *placer* as formerly adjusted; but the clock is moved and raised in such a manner that the end $l$ of the brass wire $lk$ may coincide with the end Z of the ruler YZ. The sun's rays, and the shadow of $l$ passing through R, and the point of the plummet corresponding with $o$; the pillar VX with its ruler is removed, and the cylinder C, carrying the speculum S, is substituted in its place, without altering the position of the stand P. The piece T is taken out of its place, that the tail DE of the speculum may be put through the pipe R; and when the piece T is replaced, the machine is then ready for use. The rays reflected from the speculum have the same position and direction as the ruler of the placer; and while the tail of the speculum moves with the clock, whose index follows the sun, its situation is altered with respect to the sun, but the ray reflected from the centre of the speculum remains fixed. By substituting the index K, Fig. 7. in place of NO, the machine becomes a common clock. For a demonstration of the truth of the preceding construction, the reader is referred to s'Gravesande's *Physices Elementa Mathematica*, tom ii. p. 714.

A very simple substitute for the heliostate, as proposed by Dr Thomas Young, is shewn in Fig. 8. A mirror C is fixed on the outside of a window facing the south, opposite the aperture D, through which it is required to transmit the solar rays. Another mirror is fixed by a joint to a rod AB, moveable about its axis, and parallel to the axis of the earth. The mirror A being placed in a position required for the day, so that the light which it reflects is received at such an angle upon C, that it may be transmitted through the aperture. In order to keep the ray in this position, nothing more is necesssry than to turn the axis BA round on its socket. See Young's *Nat. Phil.* vol. i. p. 426, 785. Analogous contrivances by Peyrard will be found in the *Phil. Magazine*, vol. xxxvii. p. 183, &c.

HELIOTROPIUM. See MINERALOGY.

HELIX. See CONCHOLOGY.

HELLESPONT. See TURKEY.

HELL GATE, this celebrated strait is near the W. end of Long Island Sound, opposite to Haerlem in York Island, and about 8 miles N. E. of New York city, and is remarkable for its whirlpools, which make a tremendous roaring at certain times of the tide. These whirlpools are occasioned by the narrowness and crookedness of the passage, and a bed of rocks which extend quite across it; the tides meet at Frog's Point, several miles above. A skilful pilot may conduct a ship of any burden, with safety, through this strait, at high water with the tide, or at low water with a fair wind. There is a tradition among the Indians, that in some distant period, in former times, their ancestors could step from rock to rock, and cross this arm of the sea on foot at Hell Gate.

HELMINTHOLOGY, is a term in zoology, derived from ελμινς, an *earth-worm*, and λογος, *a discourse.* Under this head are included those animals which Linnæus called *vermes.* For an account of the different orders of this class, see ANIMALCULE, CONCHOLOGY, INTESTINA, MOLLUSCA, RADIATA, and ZOOPHYTES.

HELOISE. See ABELARD.

HELSTON, a town of England in the county of Cornwall, is situated on the side of a hill, which slopes gently to the little river Cober. The town consists principally of four streets, which meet in a centre, and form a cross, and a channel of water runs through each of them. The market-house and town-hall stand near the middle of the principal street. The church, which was erected in 1762 on an eminence to the north, has a pinnacled tower 90 feet high, which forms a conspicuous sea mark. There was formerly a priory and a strong castle at Helston. Some vestiges of the castle were seen in the time of Leland. The priory of the knights of St John of Jerusalem was at St John's village, near the town. The remains of it were destroyed some years ago to make room for a methodist meeting-house. The town is governed by a mayor, five aldermen, a recorder, and sworn freemen, amounting to 36. Helston was one of the original stannary towns, but very little tin is now stamped here. Vessels take in their lading at a good harbour, a little below the town. Near Helston is a curious heap of stones, piled up in the form of a circle. It is called Earth Castle, and was formerly used as a fortification.

The population of the burgh and parish, in 1811, was,

| | |
|---|---|
| Number of inhabited houses | 328 |
| Number of families | 531 |
| Ditto employed in agriculture | 119 |
| Ditto in trade and manufactures | 166 |
| Males | 935 |
| Females | 1362 |
| Total population in 1811 | 2297 |

See the *Beauties of England and Wales*, vol. ii. p. 455.

HELVETIA. See SWITZERLAND.

HELVETIUS, CLAUDE ADRIAN, a celebrated metaphysician of the modern school, was born at Paris in January 1715. His ancestors, originally of the Palatinate, had been obliged, by their attachment to Protestant principles, to remove to Holland. His father, grandfather, and great grandfather belonged to the medical profession, and were all men of eminence. His grandfather in particular obtained celebrity by the introduction of ipecacuanha into the Materia Medica. M. Helvetius, the father of the subject of this article, was physician to the Queen of France, and held in great honour at court, was well known through Europe as a man of talents, and highly esteemed by all who knew him, for the probity of his character. He gave his son an excellent education, by placing him very early under the care of an intelligent tutor, M. Lambert. The young Helvetius was remarkably docile, and rapidly imbibed the spirit of the different authors whom he read; and from his exquisite sensibility to praise, he rendered himself an early proficient in literature, dancing, fencing, and the various other accomplishments which produce admiration. At college he became warmly attached to the philosophy of Locke. To trace all mental operations to sensation, appeared to him a happy explanation of these complicated phenomena; and he became animated with an ambitious desire to improve and extend the principles which he so much admired. At the age of twenty-three, he obtained the very lucrative situation of a farmer-general. He indulged the habits of a man of pleasure, but not without maintaining a degree of masterly prudence, which enabled him to manage his fortune without incurring inconvenience, and to give efficiency to the feelings of a noble humanity, by devoting a great part of his income to benevolent acts. He assiduously sought out and rewarded talent and merit, and always observed a delicacy of manner, which avoided the slightest wound to the pride of the most fastidious of those whom he served. Intent on the improvement of his own powers, he cultivated the society of Fontenelle, discussed along with him the doctrines of Locke and of Hobbes, and with his aid successfully cultivated the talent of expressing his ideas with perspicuity. He also became acquainted with Montesquieu and Voltaire, and profited in a similar manner by his intercourse with each of these eminent scholars. The earliest literary labour of Helvetius, was his poem on Happiness, in the composition of which Voltaire gave him great encouragement, and inculcated on him maxims which he himself had felt to be important, particularly on the indispensable necessity of truth of description, and regularity of language.

In the office of farmer-general, Helvetius was the uniform advocate of humanity, and exerted his influence to obviate the hardships to which individuals were so often liable, from the persons employed to collect the revenue. Here he had to contend with men long inured to an unfeeling system of procedure. In many of his remonstrances with the other farmers-general, his perseverance was rewarded with success: but his employment was on the whole accompanied with much disgust, and was further rendered unpleasant by the time which it occupied, and which he was desirous of devoting to philosophical studies. He therefore resigned its advantages, and with a sum of money which he had saved, he purchased an estate in the country, to which he retired. He married Mademoiselle Ligniville, after an acquaintance of 12 months, formed at the house of Madame Graffigni, the authoress of the *Peruvian Letters*. In compliance with the wishes of his father, he still passed a few months annually in the metropolis, attended court, and accepted of the situation of Maitre d' Hotel to the Queen. He took as inmates of his house two persons who had been his secretaries, chiefly from motives of benevolence. One of these, an unhappy cross-tempered and sarcastic character, of the name of Bandot, presuming on his knowledge of Helvetius in his infancy, habitually treated him as a harsh schoolmaster treats a child. This circumstance is worthy of mention, for the light which the indulgence given to him throws on the character of Helvetius. Bandot's great delight was to discuss with his master the whole conduct, talents, character, and works of the latter; and the discussions uniformly ended with satirical abuse. Helvetius, after retiring with his wife on such occasions, sometimes said, "is it possible that I am so deficient as this man represents me? I do not believe it, but I labour under these defects to a certain degree; and if I did not keep Bandot, I should have no one to point them out."

In his rural retreat, he composed his work *De l' Esprit*, or "An Essay on the Mind and its Faculties," which was published in 1758 In this work, he developed with much eloquence, and followed to some bold conclusions, the principles which he had imbibed from Locke, that all thought is a modification of physical sensation. He makes this the foundation of a system of public and private morals. This work had a powerful political effect. It was written under an impression, that the numerous evils of society are the offspring of corrupt institutions and strongly protected prejudices, and that the true source of them had been concealed by the want of analytical views of human nature and society. These fruits of his studies were presented to the world in a style and manner which were fitted to make a deep impression. His mode of representing the subject was favourable to that rage for pleasure, and that tendency to licentiousness in some points of morality, which had long prevailed in France. The author, however, in publishing it, gave a pledge of his sincerity, by risking all his honours, his property, and the whole peace of his life. His opinions were in some points wrong, and some of their tendencies were injurious; but we do not see, in his mode of stating them, marks of such haste or obstinacy as would have disinclined him to sacrifice any passion which he found really hurtful, or from renouncing the eclat of a philosophical reformer, if truth and consistency had been shown to lie on the opposite side. The points at issue between him and his adversaries were of equal importance to all, and the prohibition of his writings can only be attributed to the love of power on the part of others, and a senseless dread of the consequences of free inquiry.

He was first attacked in some of the popular journals, with criticisms, which contained some truth and plausibility mingled with marks of the lowest superstition and ignorance, and which were animated with the bitterest style of denunciation and invective. The doctors of the Sorbonne issued their censures against his heresies, which they enumerated in such concise propositions as the following: That physical sensibility produces our ideas; that pain and pleasure are the sources of thought and action; that the desire of happiness is sufficient to conduct men to virtue; that morality is, like physics, an experimental science; that vices and virtues proceed from different modifications of the desire of happiness; that virtuous actions are those which are useful to the public; that it is by good laws that mankind are rendered virtuous; and, that the chief cause of all existing vice is the ignorance of legislators, who set the interests of individuals in opposition to that of the public.

His first and most zealous enemies were the Jansenists, whose influence in the parliament of Paris procured from that body a condemnation of his work. Their rivals, the Jesuits, who had been spared by Helvetius, and with some of whom he had lived on friendly terms, made no public appearance against him till called upon by the general voice, and a regard for the character of their order. One of their number, a friend of Helvetius, conceived the plan of procuring from him a retractation of his errors. To gratify this friend, Helvetius subscribed a sort of apology, and afterwards another, which was ampler and more humiliating, with a view to save from persecution the public censor, who had suffered his work to pass the ordeal required by law. This, however, was not satisfactory: Helvetius was deprived of his situation at court; Tercier, the public censor, lost his office; and the interference of the council was necessary to save both of them from further severities, meditated by the Jansenists and the parliament of Paris.

The philosophical doctrines to which this author was attached comprehend a subject too extensive to be discussed in this article: (See METAPHYSICS.) But we find his opinions reprobated even by some liberal minds, along with those of some of his cotemporaries, as tending to degrade human nature, and destroy the dignity of moral truth. We do not apprehend, that such tendencies arose from any metaphysical opinions on the nature of matter and mind, subjects wholly unknown, and on which no opinion can be said to exist. The practical evils complained of seem to arise from a particular mode of employing words, tending to discourage all elevated conceptions, and thus generate in some individuals a degree of indignation, while its plausibility seduces others, and insensibly mars their love of moral order. An inordinate propensity to dwell on analytical views, sometimes withdraws the attention of the mind from the acknowledgment of magnificent objects. When the phenomena of mind are minutely dissected, and shown to consist of the same materials with others of a trivial nature, such as the puncture of a pin, or the titillation of a feather, all the pleasure arising from the novel exercise of acuteness, implied in the tracing of these general analogies, is of short duration, and the utmost circumspection is afterwards necessary, to resist an exclusive tendency to cherish detached sensibilities, and degenerate into a mean direction of sentiment and conduct. Persons thus influenced, consider all differences betwixt higher and meaner objects as depending on differences of arrangement, without duly acknowledging the importance of that principle of arrangement which deserves their veneration much more than minor insulated objects. The error of not acknowledging the importance of differences, merely because we are pleased with the generalization implied in the discernment of analogies, is also a radical fault in the use of the intellectual powers, tending to the same moral confusion. It is not the mere pointing out of such analogies that does harm, but the undue rank that is assigned to them. To say that virtuous and vicious actions are equally explicable on the principle of self-interest, has an apparent tendency to smooth over the difference between them. Our previous sense of their difference renders us averse to consider them as possessing any thing in common. But if any person should think it worthy of mention, that these two sets of phenomena agree in possessing the essential quality of activity, and are reducible to the varied motions of the human organs, no dangerous consequences could be apprehended, because such a position never could make a prominent figure in a moral treatise, so as to distract the mind from distinctions of essential importance.

Even a general test of morality is not sufficient to obviate the noxious effects of magnifying such analogies. The annunciation of this summary doctrine, that public utility, or the promotion of the greatest sum of pleasure, is the ultimate end of virtue, is even productive of some disadvantage. Although it may have been tacitly acknowledged, those who are averse to innovation feel in it something different from what they have considered as a definition of virtue; while those who are dazzled with it as an important discovery, satisfy themselves with vague appeals to this general ral test, in cases which require more minute discrimination, or perhaps the spirit of morality evaporates amidst the interminable disputes which those who trust in the all-sufficiency of that principle maintain about its particular applications. Some launch into an ocean of the wildest confusion, and merely because they associate their actions with the acknowledgment of this generalizing principle, imagine that they are men of superior virtue. This mode of thinking has proved a frequent source of imprudence, unhappiness, and misanthropy.

The works of Helvetius are probably less read now than formerly. This may be partly the effect of the influence of indiscriminate acrimonious censure; and, although their merit is not of the highest order, it may in a short time give way, among some readers, to an equally indiscriminate admiration. It is therefore useful to be aware of some of their tendencies, which must, on consideration, be allowed to be injurious by men of all varieties of theoretic opinion. One of the most untenable of the opinions of Helvetius was, that any differences in the original endowments of men are of no account in giving origin to the differences between mind and mind, which appear on the great theatre of the world.

The conflict which took place between the sentiments of this author and those of the age in which he lived, only afforded a specimen of a scene of hostility in moral literature which was much more extensive; and, when we consider the spirit of mutual defiance in which both parties indulged, we cannot wonder at the antipathies which it created, and the dismal political dissensions which flowed from it as soon as the restraints imposed by existing institutions were withdrawn.

The works of Helvetius were, through the influence of the French clergy, condemned by the Roman inquisition; but they were universally read and much admired in Italy and the whole of Europe. Even the dignitaries of the church, among whom was Cardinal Passionei, wrote complimentary letters, to thank the author for the fund of instruction and delight which he had afforded them.

The tide of popular sentiment, however, was so adverse to him in France, that he found it prudent to leave that country for a time. He visited England, and was much pleased with some favourable features in the state of English society as contrasted with that of France, particularly the happiness and contentment of the lower orders, the prevalent warmth of parental affection, and he even construed the want of free association among adults to their exemption from ennui, and from all dependence on frivolous amusements. He also visited Prussia, where he was received with great attention by the king, lodged in his palace, and freely admitted into his familiar parties.

When the storm raised against him in France had subsided, he returned home, and prosecuted his studies at his estate of Voré. He employed himself in extending the doctrines of his first work, in a " Treatise on Man, his Faculties and Education;" but had the prudence to give nothing more on the subject to the public. B ing attacked with the gout in his stomach, he died in December 1771.

The private character of Helvetius was distinguished by great humanity. He was a most indulgent landlord; and Madame Helvetius and he concurred in the execution of continual plans of beneficence. His lands being infested by poachers, he sometimes was provoked to punish them; but the slightest appearance of suffering produced instant reconciliation, and awakened all his benignity.

After his decease, his poem *De Bonheur*, on which he had long laboured, was given to the public. The object of this poem is to recommend literary improvement as the only source of true enjoyment. For this he has been blamed as restricting happiness to the possession of advantages which are confined to a small part of mankind. But, when we consider the life which he recommends as opposed to gross sensuality, vulgar ambition, and the pursuit of wealth, we shall find his poem to contain much valuable truth. It is equally true, that if we withdraw our attention from these limited contrasts, and leave out of view the interests of persons, who, in consequence of indulging in an inordinate passion for particular objects, have become the victims of chagrin and disappointment, we shall find happiness an object which is better secured by measures of a different kind, but which were condemned by Helvetius as haughty, stoical delusions.

His work on man was also published after his death. It is in some respects more profound than his former work; but it is written in a similar strain, and liable to the same objections. His disquisitions were conducted on a limited scale: he was betrayed by a love of simplicity into precipitate conclusions: and his pretensions were by far too gigantic, either for the extent of his talents or the success of his researches. (*H. D*)

HEMIDIAPENTE, in music, is an interval whose ratio is $\frac{45}{64}$, $= 311\Sigma + 6f + 27m$, or the *minor* FIFTH, which see.

HEMIDITONE, in music, is an interval whose ratio is $\frac{5}{6}$, $= 161\Sigma + 3f + 14m$, or the *minor* THIRD, which see.

HEMIOLIUS, in music, an interval, whose ratio is ses-qui-alterate, or 1 : $1\frac{1}{2}$; that is, $\frac{2}{3}$, = 358 Σ + 7 f + 31 m, or the *major* FIFTH, which see.

HEMIPTERA. See ENTOMOLOGY.

HEMITONES, in music, are a class of intervals of one degree of the scale, called also HALF-*tones*, HALF-*notes*, or SEMITONES, by different writers, (see these articles) all of which single degrees of the scale, although of such different magnitudes that the largest of them are more than three times as great as the smallest of them, and yet all regularly expressed by only one f, in our notation, viz.

HEMITONE of *Aristoxenus*, or ancient hemitone, is an interval whose ratio is $\frac{243}{256}$ = 46 Σ + f + 4 m, or the LIMMA, which see.

HEMITONE *artificial* of Holder, has the ratio $\frac{19}{20}$, = 45.270982 Σ + f + 4 m; see the SEMITONE of *Feytou*, &c.

HEMITONE *chromatic* of Holder and Tartini; its ratio $\frac{24}{25}$ = 36 Σ + f + 3 m, or the SEMITONE *minor*, which see.

HEMITONE *elementary* of Overend; its ratio is $\frac{15}{16}$, = 59 Σ + f + 5 m, the SEMITONE *major*, which see.

HEMITONE *greater*, of Euclid's genus Diatonum molle, $\frac{3}{10}$ths of a 4th = 76.27168552 Σ + f + 7 m; its common logarithm is .96251813,7912. = .1245114 in Euler's logs. (VIII) and 6.947433 in major comma logs. (c)

HEMITONE *greater*, of Ptolemy's genus Chromatic molle, has the ratio $\frac{14}{15}$ = 60.047096 Σ + f + 5 m; its log. = .9700367,7662, = .09953567 × VIII, = 5.553855 × c.

HEMITONE *greater* of Quintilian, has the ratio $\frac{16}{17}$, = 53.53181 Σ + f + 5 m; see the SEMITONE of *Malcolm*, &c.

HEMITONE *lesser*, of Euclid's genera Diatonum syntonum or intense, and his Diatonum molle and Toniæum chroma, $\frac{1}{5}$th of a 4th, = 50.80314496 Σ + f + 4 m; its log. = .9750122,5278 = .0830076 × VIII, = 4.631622 × c.

HEMITONE *lesser*, of Ptolemy's genera Diatonicum tonicum, and his chromatic molle, has the ratio $\frac{27}{28}$ = 32.052904 Σ + f + 3 m; its log. = .9842057,3282, = .05246742 × VIII. = 2.927559 × c. This is also the minor hemitone of Archytas; and in some experiments by Messrs Kirby and Merrick, on the sound of a pipe blown by a mixture of carbonic and hydrogen gases, and by atmospheric air, this interval resulted. See our article *Sounds of the* GASES.

HEMITONE *major*, of Archytas's chromatic genus, has the ratio $\frac{224}{243}$ = 71.947096 Σ + f + 6 m; its log. = .9646417,4474. = .1174576 × VIII, = 6.553858 × c.

HEMITONE *major* of Aristides and Feytou, has the ratio $\frac{16}{17}$, = 53.53181 Σ + f + 5 m. See the SEMITONE of *Malcolm*, &c.

HEMITONE *major* of Boethius and others, has the ratio $\frac{2048}{2187}$ = 58 Σ + f + 5 m, or the APOTOME. See that article.

HEMITONE *major* of Euler, Holder, Liston, Smith, &c. has the ratio $\frac{15}{16}$ = 57 Σ + f + 5 m, or the SEMITONE *major*, which see.

HEMITONE *major*, of Eutosthenes' chromatic genus, whose ratio is $\frac{18}{19}$, = 47.729018 Σ + f + 4 m. See the SEMITONE of *Feytou*.

HEMITONE *major*, of Ptolemy's genus Chromatic intensum, has the ratio $\frac{11}{12}$, = 76.897955 Σ + f + 7 m. See the HALF-*tone* of Brougham.

HEMITONE *maxima* of Webb, has the ratio $\frac{25}{27}$ = 68 Σ + f + 6 m, or the SEMITONE *maximum*, which see.

HEMITONE *maximum*, or greatest, of Holder, has the ratio $\frac{25}{27}$. See as above.

HEMITONE *medium* of Holder, has the ratio $\frac{128}{135}$, = 47 Σ + f + 4 m, or the SEMITONE *medius*, which see.

HEMITONE *minor* of Archytas' chromatic genus, has the ratio $\frac{27}{28}$, = 32.052904 Σ + f + 3 m. See HEMITONE *lesser* of Ptolemy.

HEMITONE *minor* of Aristides, Feytou, Quintilian, &c. has the ratio $\frac{17}{18}$, = 50.46819 Σ + f + 4 m. See SEMITONE of *Malcolm*, &c.

HEMITONE *minor* of Boethius, Sauveur, &c. has the ratio $\frac{243}{256}$, = 46 Σ + f + 4 m, or the LIMMA, which see.

HEMITONE *minor*, of Euclid's genera Chromatic toniæum, and his Diatonum molle, $\frac{1}{2}$ of T, whose ratio is 2 √ 2:3, = 52.0039312 Σ + f + 4 m; its log. = .9744237,3877, = .084962 × VIII, = 4.74070 × c. It is also the chromatic diesis of Hoyle.

HEMITONE *minor* of Euler, Holder, Sauveur, &c. has the ratio $\frac{24}{25}$, = 36 Σ + f + 4 m, the SEMITONE *minor*, which see.

HEMITONE *minor*, of Eutosthenes' chromatic genus, has the ratio $\frac{19}{20}$, = 45.270982 Σ + f + 4 m. See SEMITONE of *Feytou*, &c.

HEMITONE *minor* of Ptolemy's genus Chromatic intensum, has the ratio $\frac{21}{22}$, = 41.198802 Σ + f + 3 m; its log. = .9797966,1391, = .06711422 × VIII, = 3.744815 × c.

HEMITONE *minimum* of Holder, improperly so called, because it belongs to the class of commas (wanting f,) rather than to that of semitones; its ratio is $\frac{625}{648}$ = 32 Σ + 3 m, or 31.8582014 Σ + f + 2 m, the SEMITONE *minimum* of Overend, which see.

HEMITONE *Pythagorean*, or ancient, has the ratio $\frac{243}{256}$, = 46 Σ + f + 4 m, the LIMMA, which see.

HEMITONE *subminimis* of Holder, has the ratio $\frac{243}{250}$, = 25 Σ + f + 2 m, the SEMITONE *subminimis*, which see. (g)

HEMLOCK, a lake in New-York state, twelve miles long, and one broad, in the Genessee country.

HEN. See ORNITHOLOGY.

HENFLING'S *Temperament* of the musical scale. In the year 1711, M. Henfling communicated to the Parisian Academy a commensurate system of 50 equal intervals within the octave; of which parts, 29 make the fifth, which therefore, for imperfect instruments, will stand as follows, viz.

11 Fifths, viz. on C, G, D, A, E, B, ♯F, and ♯C, and on F, ♭B and ♭E, each equal to } 354.951969 Σ + 7 f + 31 m, = 3904.471659 Σ + 77 f + 341 m.
And the wolf fifth ♯D ♭E . . . . . . . . . . . . . . . . . . = 379.528341 Σ + 7 f + 30 m

Make 7 octaves each, 358 Σ + f + 53 m. . . . . . . . . . . . . . = 4284.000000 Σ + 84 f + 371 m.

And whence all its other intervals may easily be calculated, by help of the theorems, *in Phil. Mag.* vol. xxxvi. p. 41, or the corollaries at p. 374; see also p. 50, of the same volume. Dr Robert Smith, in Prop. xvii. of his "Harmonics," has calculated the temperaments of this system, and shewn, that it approaches extremely near to his system of EQUAL *Harmony* in three octaves. See that article.

HENGIST. See ENGLAND.

HENLEY UPON THAMES, a town of England, in the county of Oxford, is situated on the left bank of the river Thames, which is crossed by a fine bridge of five arches, with a handsome ballustrade instead of a parapet. The keystones in the centre arch contain two heads of the Thames and Isis, which were sculptured by the Honourable Mrs Damer. The town consists of two principal streets at right angles to each other, and some smaller ones.

The street which extends from the bridge to the cross is not very long, but is spacious, and contains some good houses. The street which extends from the cross along the Oxford road has a serpentine direction. It is longer than the other, and contains many excellent houses. At the junction of these streets is a simple stone obelisk, pointing out the direction of the roads, and the distances from London. The church, which is a very ugly building, is situated near the bridge, on the west side of the street. It has a tower with semi-octagonal buttresses at each angle, and embattled at the top. It is built of flints and stones. The tower is said to have been built at the expence of Cardinal Wolsey. The other establishments in Henly are a Royal Grammar School, founded by King James V. for educating 25 boys in the classics; a blue coat school, founded by Dame Elizabeth Perians, for educating and clothing 20 poor boys; a green coat school, and an alms house. Henly carries on a considerable trade with London by means of the Thames, in malt, flour, and beechwood. Above 30,000 quarters of flour are annually made here.

The following is the population of the town and parish in 1811.

| | |
|---|---|
| Number of inhabited houses | 522 |
| Do. of families | 543 |
| Do. employed in agriculture | 93 |
| Do. in trade and manufactures | 235 |
| Males | 1347 |
| Females | 1770 |
| Total population in 1811 | 3117 |

HENLEY HOUSE, a station of the Hudson Bay Company, on the north bank of Albany river, in New South Wales, 150 miles S. W. of Albany Fort, and 110 N. W. by W. of Brunswick House. N. Lat. 51, 14, 27, W. Lon. 85, 5, 54.

HENLOPEN, Cape, forms the S. W. side of the entrance of Delaware Bay, and Cape May, the N. E. side, 28 miles apart. Cape Henlopen lies in N. lat. 38° 50′, and in W. lon. 75° 26′. There is a light house here, a few miles below the town of Lewis, of an octagon form, handsomely built of stone, 115 feet high, and its foundation is nearly as much above the level of the sea. The lantern is between 7 and 8 feet square, lighted with 8 lamps, and may be seen, in the night, ten leagues off at sea. Its annual expence is about 650*l*. There is a strong iron net work, in order to prevent birds from breaking the glass at night. Yet so attractive is the light to the winged tribe, that shortly after its erection, 110 birds of different kinds were found dead one morning, and a duck in particular, flew against it with such force, as to penetrate through both the wire and the glass, and was found dead in the lantern. Since this birds have become more wary. Vessels off Delaware, upon displaying a jack at the foretopmast head, will be immediately furnished with a pilot. None, however, are to be depended upon, unless they are furnished with branches, and with a certificate from the board of wardens of Philadelphia.

HENRIQUELLE, a remarkable salt pond in the Spanish part of the island of St Domingo, about 22 leagues in circuit. It is inhabited by lizards and alligators, and land tortoises, all of a large size. The water is deep, clear, bitter, and salt, and has a disagreeable smell. Near the middle of this pond is an island about two leagues long, and a league wide, in which is a spring of fresh water, well stocked with *cabritoes*, and thence called *Cabrito Island.* This pond is about 11 leagues east of Port au Prince.

HENRY, Cape, the north-eastern extremity of Princess Ann county in Virginia, 12 miles S. by W. of Cape Charles in Northampton county. These capes form the entrance of Chesapeake Bay. Cape Henry lies in N. lat. 37, W. lon. 76 16.

HENRY I.—VIII. of England. See England.

HENRY I.—IV. of France. See France.

HENRY, Patrick, late governor of Virginia, was born about the year 1740 From all that has been recorded of him, what was precisely the condition of his parentage does not clearly appear. The chronicles of the provincial governments in North America, of the revolutionary war, and of the governments of Virginia and the United States since the year 1776, afford less satisfactory information of Mr Henry, and his specific services, than of any other man, at all distinguished in those several eras. He was born at a time, and among a people, when, and with whom, family legends were not very fashionable; unless they could be gilded by the lustre of office, or by the more imposing, though stupid pageantry of opulence. In the colonial era, the agents of the crown, and those advantageously connected with the public offices, were most generally from the mother country. The public archives, therefore, contain few traces of persons not in the confidence or employment of the provincial governments.

From the accounts most to be relied on, Mr Henry was of an obscure family. His education was limited; and poorly calculated to form an ordinary genius for eminence. His elevation, fame, and influence, resulted from unlettered, unadorned, but strong intuitive faculties. His gigantic mind bounded over all juvenile preparation for the active scenes of life. He was formed by nature a prophet among the most wise and most learned. He was therefore excused from the tardy, and sometimes discouraging, process of scholastic ratiocination; and, at the age when others yield blossoms of hope, often blighted by towardness or adversity, he was covered with delicious and matured fruit. He was a man of genius, eloquence, and virtue. He stepped on the stage of life without previous notification; and selected and acted his own character without the ceremony of rehearsal. His appearance commanded applause; his performance was followed by universal eclat; and his exit left his country in tears. In every situation of life he manifested an accurate perception and love of truth, which he always courted as the charm of his affections; and clearly demonstrated, by all his calculations and conclusions, that judgment taught him what experience alone could teach his cotemporaries.

At the age of twenty-five, Mr Henry was elected a member of the general assembly of Virginia. During the session of 1765, he introduced, for the consideration of the legislature, certain resolutions, fraught with the spirit of popular liberty, and pointedly protesting against the tyranny of the British government, which had then begun to be displayed with iron features in all the colonies, more especially in Virginia. The resolutions were approved by a majority of the assembly, and were the first adopted by any of the colonial legislatures against the famous stamp act. They not only declared what was tyranny and usurpation on the part of the mother country, and in contravention of chartered rights; but also defined the privileges and immunities of the colonists. These resolutions were the commencement of that opposition, which, though varied from time to time, ultimately resulted in the establishment of the independence of the United States. The debate on them was turbulent and proscriptive on the one side; zealous, determined, and vehement, on the other. The apologists of British tyranny raised the cry of "*treason!*" against the advocates of liberty and the rights of the colonists. In the midst of the storm, Mr Henry, until then unknown, burst forth with the thunder of his native eloquence; seared the visages of his haughty antagonists by his consuming scowl; and dealt out threatened vengeance on all, who should dare to array themselves against a people determined to assert their freedom. Encouraged by the undismayed front of their champion leader, his associates joined his standard, and marched boldly with him to the point of decision. It is recorded, in the reports of that celebrated parliamentary rencounter, that though the British authority remained yet unbroken, the old system of sergeantry still continued of force in the country, and the very hall, in which the assembly of Virginia convened, was thronged by his majesty's officers and procurers, Mr Henry, stimulated by the insolent and menacing denunciations of himself by his royal antagonists, exclaimed: "Cæsar had his Brutus, Charles the First a Cromwell, and George the Third——" here he was called to order by the presiding officer.

Mr Henry was not destined by his parents, or qualified by education, for any public profession. He grew up in the wonted occupations of a husbandman. Although accustomed to read, at leisure seasons, for his improvement and the gratification of an early taste for books, he had not adjusted himself to the design of becoming a public speaker. He always manifested a singular disinclination to court popularity. He inherited from nature splendid qualifications to become the theme of popular applause, and the deity of democratic idolatry; notwithstanding, from the commencement of his blazing career, he shrunk from the contact of vulgar associates; nor did he ever in his life swerve from the majesty of his spirit, the elevation of his sentiments, or the dignity of his deportment, from the consciousness of his ascendency over the taste and passions of the multitude, attracted by the benevolence of his enthusiastic heart, the ardency of his devotion to liberty, and the spell of his rapturous eloquence.

Virginia is indebted to one of those singular providences, which sometimes exhibit prodigies in the natural and moral world, for the ultimate and more accomplished developement of the intellectual powers of Mr Henry. Some time after his debut in the Virginia assembly, he was appointed an executor by the will of a deceased neighbour, whose estate happened to be involved in considerable litigation. In the execution of the task committed to him, he was obliged frequently to be in court; and to his counsel discovered a wonderful aptitude in business. His wariness, industry, correct apprehension of the testimony necessary to gain his ends, his method in preparing his cases for trial, and unerring anticipation of his antagonists, left nothing to be done by his counsel. Thus he developed the qualities essential to success in a lawyer or advocate. Those who witnessed the display of his talents, in the capacity of client, had the generosity to encourage their cultivation. They persuaded Mr Henry to prepare himself for the practice of the law. Though now considerably forward in years, and past the time most suitable to lay the foundation of eminence in any profession, he yielded to their persuasion, and actually commenced the study. In a short time he underwent examination, was found duly qualified, and enrolled one of that very honourable and useful fraternity, to which the people of the United States are much indebted for the great and inestimable blessings they enjoy. It is but justice to the memory of Mr Henry, to state, that he contributed much to enhance the respectability of the profession he selected and pursued; and, more perhaps than any other individual, to remove from the public mind an unreasonable prejudice against lawyers. He embarked in the practice immediately after his admission, and, contrary to his own expectation, for he was a man of little vanity, and of great humility in the estimation of himself, advanced suddenly to the first eminence. He became particularly famous as a criminal pleader. He was employed in every important case in his usual circuit, and generally on his own terms. Indeed so imposing was his fame, that he was frequently engaged in distant circuits; and no litigant conceived his cause safe when opposed by the peculiar talents of Mr Henry.

In 1774, he was appointed one of the deputies from Virginia in the first congress of the confederated colonies; and was a member of the committee of that body who drew and reported the petition to the king, which was afterwards voted. In May of the following year, Lord Dunmore, governor of Virginia, caused to be conveyed on board of a transport vessel a quantity of powder from the public magazine at Williamsburgh, to secure it from seizure by the citizens. Mr Henry assembled several volunteer militia companies, of Hanover and Prince William counties, and marched to Williamsburgh, with the avowed determination to compel a restitution of the powder to the magazine, or to enforce payment for it upon a fair valuation. His purpose was completely effected. To avoid the more serious alternative, the receiver general gave a bill for the amount, and the powder, from prudential motives, was retained by the governor. The spirit and decision of Mr Henry on this occasion left no room for hesitation. He submitted a choice of alternatives, which were, *restore*, *pay for*, or *fight for the powder*.

Lord Dunmore, foreseeing an approaching crisis, fortified his residence, and issued a proclamation against those concerned in the late enterprise, charging them with rebellious practices. The governor's proclamation only produced a counter-declaration. The people immediately thereupon assembled in county meetings, testified their approbation of Mr Henry, declared his conduct patriotic, and exchanged pledges to protect him against the vengeance of the governor. Lord Dunmore having departed for England in 1776, Mr Henry was chosen governor of the commonwealth. In this office he continued several years, using all means in his power to promote the freedom and independence of his country.

In the year 1778, the aspect of the revolution became exceedingly gloomy. Several dangerous intrigues were instituted to pull down the popularity of general Washington, and supplant him in the command of the army. One of the most serious occurrences of this sort was a cabal of general officers, members of congress, and some influential citizens. Their scheme against the amiable chief was to be effected by the circulation of anonymous letters to distinguished and influential gentlemen in various sections of the country, suggesting objections against the military conduct and character of the commander in chief. One was addressed to governor Henry, a man universally reputed a patriot of the first energy and influence. With his wonted shrewdness, he instantly discerned, through the anonymous disguise, the real motives of the authors. He concluded at once that the letter covered sinister, ambitious, and traitorous designs against his friend, in whom he continued to repose immutable confidence. With the magnanimity that belonged to his noble heart, a promptitude inspired by his devotion to the cause of liberty, and an indignation at the manner in which his own integrity had been assailed, he decided against the calumniators of Washington; and, to apprize him of the danger that surrounded him, communicated the anonymous libel to him, with such remarks as the occasion required. The correspondence between the two friends on this occasion was equally honourable to the candour, prudence, and intelligence of both.

Mr Henry retired from the government of Virginia, and sought some repose from the labours of public life, in the bosom of his family, and in the society of his neighbours; but his heart continued earnestly importunate for the success of the revolution. While in retirement, his conversation at home, and his correspondence with public functionaries at a distance, imparted instruction, and inculcated zeal and perseverance in the great cause of national liberty.

In 1788, Mr Henry was a member of the convention in Virginia, which so ably and eloquently discussed the constitution of the United States, and the expediency of its adoption. The part he took in the convention is familiar with the public. He employed his masterly eloquence, day after day, in opposition to the proposed constitution. His hostility to it proceeded entirely from an apprehension that the federal government would swallow the sovereignty of the states; and that ultimately the liberty of the people would be destroyed or crushed by an overgrown, ponderous consolidation of political power. Mr Henry would cordially have delegated to the government of the United States, a few specific powers, to preserve reciprocal interests, and constant alliance among the several states; and to regulate the relations of the whole with foreign nations. This in a few words was the government he wished to see adopted. Every feature in his opposition to the constitution cannot here be traced. It is enough to affirm, that he opposed it from pure and patriotic motives, a fixed hatred of despotism, jealousy of political power, and a constitutional enthusiasm in behalf of liberty. That such were the motives of his conduct, his future deportment amply testified. The constitution having been adopted, the government organized, and Washington elected president, his repugnance was measurably abated. The chapter of amendments considerably neutralized his objections: but nevertheless it is believed, that his acquiescence resulted more from the consideration of the citizen's duty, confidence in the chief magistrate, and a hopeful reliance on the wisdom and virtue of the people, rather than from any material change in his opinions. It is worthy of remark, that, in relation to the federal government, Mr Henry and Mr Hamilton, two of the most eminent men who have ever lived in the United States, entertained opposite fears. The first dreaded its energy; the latter its imbecility. Many will suppose that experience has already shewn, that the jealousy of the powers delegated to the general government was morbid and fantastical: but it may be remarked, that a few years, characterised by fortuitous circumstances, is not an alchemy to analyze the properties of any form of government. The experience of the United States has shewn, in the period of twenty-eight years, that their government is energetic or feeble, according to the heads and hearts of their chief magistrates. This is probably true of every government.

In August 1795, Mr Henry was nominated by president Washington, secretary of state, in the room of Mr Edmund Randolph, resigned; but considerations, wholly of a private nature, induced him to decline the honour. In the course of the succeeding year, he was again elected governor of Virginia. He entered on the duties of the office: but in a few months retired to his domestic circle. Early in the year 1799, Mr Henry was selected by president Adams joint envoy with Messrs Ellsworth and Vans Murray to France. His advanced age, increasing debility, and a severe indisposition, with which he was at the time afflicted, obliged him to decline the appointment. In the spring afterwards, at the special solicitation of general Washington, he became a candidate, in the district composed of the counties of Halifax, Charlotte and Prince Edward, for a seat in the senate of Virginia. Events preliminary to the election are memorable. At the same election Mr John Randolph, for the first time, declared himself a candidate, in the congressional district of Buckingham, Cumberland, Prince Edward, and Charlotte, for a seat in the house of representatives of the United States, in competition with Mr Clement Carrington, a federalist, and Mr Powhatan Bolling, a democrat. In canvassing before the election, Mr Randolph encountered Mr Henry, and his competitors for the honour of a seat in congress. It is a custom in Virginia for candidates to harangue the people in support of their personal pretensions and political principles. Mr Henry and Mr Randolph, on this occasion, conformed to this custom, and were publicly exhibited as political combatants, before the voters of Charlotte county. They met at the court-house, and supported a long and animated discussion of various topics. Mr Henry, in opening, maintained his long established reputation as a declaimer. On finishing his harangue, he literally descended into the arms of the obstreperous throng, and was borne about with triumphing exultation. His opponent might well have been deterred from ascending the stage: but his courage decided otherwise. Mr Randolph rose in the face of the success of his predecessor. His singular person and peculiar aspect; his novel, shrill, vibratory intonations; his solemn, slow-marching, and swelling periods; his caustic crimination of the prevailing political party; his cutting satire; the *tout ensemble* of his public *debut*, soon calmed the tumultuous crowd; and inclined all to listen to the strange orator, while he replied at length to the sentiments of the old favourite. When he had concluded, loud huzzas rang through the welkin. This was a new event to Mr Henry. He had not been accustomed to a rival; and little expected one in a beardless boy; for such was the aspect of the champion, who now appeared to contend with him for the palm which he was wont to appropriate to himself. He returned to the stage and commenced a second address, in which he soared above his usual vehemence and majesty. Such is usually the fruit of emulation and rivalship. It has been admitted, that Mr Henry displayed his greatest splendour on this occasion. He frequently adverted to his youthful competitor with parental tenderness; complimented his rare talents with the liberality of profusion; and, while regretting what he deprecated as the political errors of youthful zeal, actually wrought himself and his audience into an enthusiasm of sympathy and benevolence that issued in an ocean of tears. The gesture, intonations, and pathos of Mr Henry, operated like an epidemic on the transported assembly. The contagion was universal. An histerical phrenzy pervaded the whole audience to such degree, that they were at the same moment literally weeping and laughing. At this juncture the speaker descended from the stage. Shouts of applause rent the air, and were echoed from the skies. The whole spectacle, as it really was, would not only mock every attempt at description, but would almost challenge the imagination of any one who had not witnessed it. With a recollection of the event, Mr Randolph, eighteen years afterwards, in his place in the house of representatives of the United States, speaking of the general ticket law, which was carried by the democratic party by a majority of five votes only, in the popular branch of the Virginia assembly, said: "Had Patrick Henry lived, and taken his seat in the assembly, that law would never have passed. In that case the electoral vote of Virginia would have been divided, and Mr Jefferson lost the election. Five votes! Mr Chairman!

Patrick Henry was good for five times five votes." In the contest above mentioned, Mr Henry was elected to a seat in the senate of Virginia, and Mr Randolph a representative in congress. Mr Henry, however, did not live to take his seat. He died at Red Hill, in Charlotte county, on the 6th of June, 1799, aged sixty-seven years.

In private life Mr Henry was as amiable and virtuous, as he was brilliant in his public career. He was an exemplary christian; and his illustrious life was greatly ornamented by the religion he professed. His memory will be dear to every believer in the sacred Scriptures, for the steady and fearless example he exhibited in the observance of religious duty. In every situation he was studiously respectful of religious characters. He was accustomed to speak of the providence of God, which was munificent to him, in the most grateful and submissive terms. His conversation, private letters, and public speeches, evinced a constant and reverential regard of the Deity; and, many years before his death, he spent much of his time in religious reading and reflection. The Bible commanded his cordial accredence; and he was accustomed to say to his friends, and especially to his sons, that its rejection was certain evidence of a depraved understanding and corrupt heart, frequently the presage of infamy in this world, and always the harbinger of adversity in that which is to come. He was benevolent and hospitable to ministers of the gospel, whom he regarded as the heralds of peace and good will among men. He considered them not only necessary to the prosperity of the church, but greatly beneficial to civil society. In the temperament of his heart he was ardent, and, on all subjects which interested his feelings, his sentiments were expressed with energy and pathos. In his rhapsodies on freedom and religion, he would say, that, without the Bible and ministers, liberty would become licentiousness, and man more savage than the roaming tigers. In short, he was decided in the sentiments, that there was no liberty without religion; that christianity was the source of every human blessing; that without it there was no morality, nor restraint on the passions of the heart; that there never was, nor could be, a free and happy people, who did not assume the christian religion and its precepts as the basis of civil authority; and that the banners of the cross were the only standard under which men could be directed to a happy destiny. In consonance with these sentiments, he also declared that the infidel is a rebel against God and a traitor to mankind; that licentiousness, anarchy, and despotism, are the consequences of sin, and the offspring of hell; and that ruin would ever be the end of every empire, whose government is founded alone on the blind philosophy of free thinkers, and on the light of human reason.

Mr Henry abhorred human slavery in every shape. In a letter to a friend he expressed his feelings and sentiments on the condition of Africans in the following manner: "Is it not amazing, that, at a time when the rights of humanity are defined and understood with precision; that, in a country, whose inhabitants, more than those of any other, fondly cherish a love of liberty; that, in such an age, and in such a country, we should find men. professing a religion the most humane, mild, gentle, and generous, adopting a principle as repugnant to humanity as it is inconsistent with the Bible, and acquiescing in a practice wholly destructive to liberty? Would any one believe, that I am master of slaves—slaves of my own purchase? I am drawn along by the general inconvenience of being here without them. I will not, cannot justify it. I believe, I hope a time will come, when an opportunity will offer to abolish the lamentable evil. Every thing we can do is to improve it, if it happen in our day; if not, let us transmit to our posterity, together with our slaves, a pity for their unhappy lot, and an abhorrence of slavery."

Mr Henry, like Washington, was never out of the United States. He had no attachment to office; but uniformly preferred private life to public stations. He could only be diverted from his preference by imperious duty to his country, and the generous desire of benefitting mankind. Hence it will be found that he occupied comparatively few public stations, either in the state or general government. It is not more wonderful than true, that he never accepted of any office under the government of the United States, though frequently solicited, and more than once appointed. He accumulated a great estate by the practice of the law, and a judicious application of his time, genius, and industry. As his ambition never ran on offices and salaries, he never imbibed those morbid, baneful party feelings, which have too frequently engrossed the motives of public men, and seriously prejudiced the prosperity of the United States. In a letter to a friend, written a few months before his death, he used the following terms: "I deprecate the violence of parties in Virginia; and lament French infidelity, manners, and politics. I am too old and infirm to undertake public concerns. I live much retired, amidst a multitude of blessings from the gracious Ruler of all things, to whom I owe unceasing acknowledgments for his unremitted goodness to me: but if I were permitted to ask that one more might be added to the catalogue, it should be, the pleasure of seeing my countrymen learn wisdom in this their day, and know the things that pertain to their peace."

HEPATICÆ. See Fuci and Lichen.

HEPATITES. See Medicine.

HEPTACHORD *major*, in music, an interval, whose ratio is $\frac{8}{15}$, = 555 Σ + 11 f + 48 m, or the *Major* Seventh, which see.

Heptachord *minor*, has the ratio $\frac{5}{9}$, = 519 Σ + 10 f + 45 m, or the *Comma redundant minor Seventh*, which see.

Heptachord *minor* of Galileo, has the ratio $\frac{9}{16}$, = 508 Σ + 10 f + 44 m, or the *Minor* Seventh, which see.

HEPTAGYNIA. See Botany.

HEPTAMERIS, or Eptameris. In the new musical notation of M. Sauveur, which he had laid before the Academy of Sciences at Paris in 1701; he assumed, that the reciprocal logarithm of the octave may, without sensible error, be taken to be .301, instead of .3010299,9566; and which number of his being divisible by 7, he called each of these seventh parts of the octave a Meride, (see that article,) whose recip. log. = .043; and each of these 43d parts of the meride, or 301st part of the octave, he called a Heptameris. This interval is therefore = 2.04057055Σ; its common log. = 9989999,0035, which M. Sauveur assumed to be .9990000 0000, or 2.0403712Σ: it is equal .00332226 × VIII, = .185374 × c: he again divided his heptameris into ten equal parts, and called each of these a Decameride. See that article.

HERACLEA. See Greece.

HERACLIDES. See Greece.

HERALD. In the histories of the heroic ages, we find important functions ascribed to those officers whom the

Greeks call κηρυκεσ, and the Romans *feciales*. Their character is represented as sacred and inviolable; and in Homer, their common epithet is "*the divine*." Their duties were not less numerous than important. They could enter without difficulty into cities that were besieged, and mingle without danger among contending armies. They summoned the chiefs to the council; they commanded silence, that the discourses of the kings might be heard; and presented to each of them the sceptre before he commenced his harangue. The herald was charged with the most delicate missions, and accompanied his prince on the most difficult occasions. Agamemnon sent only Talthybius and Eurybates to bring Briseis from the tent of Achylles; and when Priam went to beg the body of his son, he took no one with him but his herald. The herald was distinguished by a long rod or sceptre, which he carried in his hand; and from this circumstance it was, that the Romans gave him the name of *caduceator*. Eckhel has published a beautiful medal of Crotona, from which we may judge of the dress of a κηρυξ, at a time much later than the age of Homer. He is arrayed in a long tunic like that of a priest, and holds in his hands a *patera* and a *caduceus*. The *patera* denotes a libation or offering to the gods, a function with which the heralds were frequently charged. According to Eckhel, this herald is in the act of demanding peace, and the coin was most probably struck at the time when the people of Crotona, humbled by a severe defeat, were obliged to send envoys to beg peace of the Locrians. The attitude of stretching out the right hand seems to have been considered as consecrated to the use of heralds; and it is on this account, that, on the imperial medals, the emperor is commonly represented in the same position, when he announces peace and security to his people.

The use of heralds was very long preserved among the Greeks. There were heralds whose office it was to proclaim the laws observed at the olympic games, the names of the combatants and the victors, and, in general, every thing which was commanded by the judges of the games. The best account of the κηρυξ of the Greeks, and the FECIALIS of the Romans, is to be found in the works of Grævius and Pitiscus: or, if ancient authors be preferred, in Homer throughout: in Livy, i. 32; Cicero *De Legibus*, ii. 9; and Dionysius Halicarnass. lib. 2.

In the middle ages, also, the heralds perform a part of considerable importance. The origin of their name seems to be entirely uncertain, and it is difficult to say which of the sixteen theories mentioned by Edmonstone is the most ridiculous. The date of their institution in the form of a college, in most of the European kingdoms, is equally obscure. The first king of arms of whom mention is made in the French chronicles, is Robert Dauphin, who was alive A. D. 1031. But the conjecture seems by no means unlikely, that the French borrowed the idea of a regular body of men charged with the care of armories, processions, and ceremonies, from the *veterani* of the empire. See *Bertrand Caprioli*, under the word MILITIA, as cited by Upton *De Militari Officio*, lib. i. cap. 8. In England it does not appear that any such officer as the herald was ever employed on missions by William the Conqueror, or either of his sons. Yet there can be no doubt that the office was familiar to Robert Curthose and Richard Cœur de Lion, both of which princes were so renowned in the wars of the cross, and had so many opportunities of mingling with foreign kings, in whose countries the heralds were already openly protected by the law. Very shortly, at all events, after this period, we find the heralds in full possession of all the privileges to which they ever attained, either in this island, or on the continent. They were allowed free entrance into the courts of all princes and great lords; they had power to reprove the faults of nobles, knights, and esquires; and if these did not amend, to exclude them from all tournaments and martial exercises. It belonged to the heralds to advertise knights and military commanders of the day of battle, to attend their sovereign's great standard in their best ornaments. They were, during the battle, to retire to an eminence, to witness what was done on either side, and report to the king or general those who behaved most valiantly, and commit the same to writing. When the battle was over, it was their province to number the dead, to ransom the prisoners, to summon cities, and, in case of composition, to march before the captain or governor, for security of his person. At justs and tournaments, it was the office of the heralds to carry all challenges, to lay out the lists, and assign places to the combatants. Such as wronged them, and refused to give full satisfaction, were declared guilty of high treason, and punished accordingly. An instance of which occurred in Scotland, A. D. 1515, when the Lord Drummond was solemnly forfeited in parliament, *Eo quod Leonem armorum regem pugno violasset cum eum de ineptiis suis admonet;* and it was upon that lords's humble submission, and at the earnest intreaty of the Lyon himself, that he was restored.

The society of heralds in England, consists of four kings of arms, who are called *Garter King at arms*, *Clarencieux*, *Norroy*, and *Bath*, whereof the first and last derive their names from the two orders of knighthood to which they owe their establishment; and the other two are provincial kings of arms, Clarencieux having power over all the east, west, and south provinces, as far as the river Trent; and Norroy, in like manner, over all parts of England north of the Trent; six heralds, viz. Somerset, Chester, Windsor, Richmond, Lancaster, and York; four *pursuivants*, who may be considered as the apprentices of heraldry, viz. Ronge-dragon, Portcullis, Blue-mantle, Rouge-croix. All these persons, (kings, heralds, and pursuivants) are by the King himself, or Earl Marshall, "crowned with crowns, graced with colours, attired with coats, named by names of addition, and with other ceremonies created."

In Scotland there is one king at arms, who derives his name of *Lyon* from the bearing of our kings. Under him are six heralds distinguished by local names, viz. *Snawdon*, *Albany*, *Rosse*, *Rothesay*, *Marchmont*, and *Ilay;* and five pursuivants, viz. *Unicorn*, *Carrick*, *Kintyre*, *Ormond*, and *Bute*. Besides these, the great nobility in England and Scotland had formerly heralds and pursuivants attached to their own service: as *Blanche Lyon*, the herald to the Duke of Norfolk; *Lion d'or* to the Dudleys; *Percy herald* to the Earls of Northumberland, &c. Le Laboureur is of opinion, that counts and high barons, who are not princes, may have heralds and pursuivants; and that knights bannerets may have pursuivants only, unless they be invested with some high dignity, as marshal or general of the army: (See *Origine des Armoiries*, p. 121.) The king of arms in France, was always known by the name of *Mont-joye St Denis*. His heralds, to a considerable number, derived their names from the different provinces of France; and his pursuivants were called, *Plain chemin*, *Voir disant*, *Haut-le-pied*, *La verdure*, *Gaillard-bois*, &c.

See Æneas Sylvius *De Officio Heraldorum*. *De l'Office des Rois d'Armes*, &c. par Marc de Vulson de la Colombiere, Paris, 1645; and particularly the *Traité du Roi René*, which is there printed; *Le Theatre d'Honneur*, par André Favin; and Edmonstone's *Heraldry*, vol. i.

# HERALDRY.

1. The art of the herald, known also by the names of "the art of blazon," "the art armorial," and "the art noble," consists, strictly speaking, in the knowledge of armories, and their due application, as ensigns of honour, and tokens of descent. The meaning of the term, however, is often extended, so as to include the knowledge of the ceremonial to be observed in all public assemblies of those who bear arms; such as cavalcades, processions, and the like.

*On the Origin of Armories.*

2. No subject has given rise to greater diversity of opinion among antiquarians, than the origin of armorial ensigns. The writers of the 16th and 17th centuries, who still continue to be the chief authorities on this subject, seem in general to have been infected with the desire of adding new consideration to their favourite pursuit, by maintaining that the art of blazon, so far from being the production of the middle ages, had been framed by the first masters of science among mankind, and practised in a manner little different from that of their own times, by the most polished nations of antiquity. The disquisitions of several great French and English heralds, indeed, and particularly those of Father Menestrier, had gradually brought into contempt the dreams of their more enthusiastic predecessors; and it appeared, that such fanciful opinions were wholly exploded among men of sound understanding, till of late years some of the most ridiculous of them have been revived in all their original extent, and defended with a show of learning more imposing than had ever before been called into their service, by a French writer of eminence, M. Court de Gebelin, in the 8th volume of his *Monde Primitif*. This ingenious author does not, indeed, after the example of Mr Sylvanus Morgan, commence his treatise with a description of the armorial bearings of the first parents of our race. He does not affirm, that "Abel quartered with his paternal escutcheon, *argent an apple vert*, for his mother Eve, who was an inheritrix;" nor mention Joseph, as receiving "an honourable augmentation to his coat, in consequence of his being invested with the family order of Pharaoh king of Egypt." But he is seduced, by his fondness for a very untenable theory, into absurdities scarcely less glaring than these, when he talks seriously of the word *ingenuus*, as equivalent to "a person who has a right to armorial bearings;" and refuses to perceive any difference between the personal or political emblems of the Greeks and Romans, and the systematic heraldry of the modern nations of Europe.

3. Since, however, the subject has so lately been agitated by a writer of such learning and reputation, it may not be amiss to examine somewhat more at large into the merits of the case, by investigating not his opinion alone, but the more probable of all those theories which have been supported by the most eminent of the heraldic authors. According to many of these writers, the use of armorial bearings was the invention of the ancient Egyptians; and in support of this opinion two passages from Diodorus Siculus are alleged; in the first of which it is said, that "Anubis and Macedon, the sons of Osiris, were the first who carried in war marks of distinction, taken from certain animals, symbolic of their valour," (*Bib. Hist.* lib. i.); and in the second, that "the Egyptians, observing that their troops were liable to be scattered in battle, invented certain signs, by which they might be able to recognize each other. And that making use of the figures of animals for this purpose, such a veneration was by degrees conceived for these images, that the animals themselves came to be considered as sacred and inviolable beings."

A second set of writers assert that this art took its rise among the Hebrews; and the Rabbins of later times have been at pains to lend all their learning to the defence of this opinion, by blazoning, in the most scientific manner, the coats-of-arms of all the principal personages mentioned in holy writ.* The only passage of Scripture which they seem to quote with confidence in support of their theory, is Numbers ii. 2. "Every man of the children of Israel shall encamp by his own standard, with the *ensign* of his father's house." But the weakness of any argument derived from this text will be sufficiently manifest in the sequel.

The third opinion is that of those who ascribe the first practice of heraldry to the ancient Greeks. And the defenders of this doctrine never fail to cite with great exultation those verses of the ΕΠΤΑ ΕΠΙ ΘΗΒΑΙΣ, in which Æschylus describes the bucklers of the seven Captains of the assailing army.

The fourth opinion is, that the practice of using armorial bearings was never reduced to any regular system till Augustus instituted legionary marks of distinction, and caused these symbols to be engraved and painted on the shields of his soldiers.

Fifthly, It is by no means an uncommon theory, that Charlemagne was the first patron of the heraldic art, in as much as after regulating the dignities and offices of the imperial palace, and establishing the order of peers, he instituted certain marks of honourable distinction, by which the great personages of his court might every where be recognised. It is true that the history of St Louis, by Joinville, speaks of armorial bearings conferred by Charlemagne on the Viscounts of Conserans, of the house of Comminges, and that the romances are full of those of Orlando, and the other heroes of that age. But it is fair to mention, that these authorities are equally conclusive respecting the coat-armour of Arthur, and the knights of the round table; so that the claims of Charlemagne to the honour of this institution are somewhat dubious, even by the admission of his most strenuous admirers.

A sixth party ascribe the origin of these insignia to the wars which the Franks carried on in the East against the infidel possessors of the Holy Land; and derive many arguments in support of their opinion from the ancient charters for the foundation and endowment of monasteries.

Seventhly, The Italians are unanimous in fixing the origin of the art in the times of the Emperor Frederic, when their country was torn in pieces by the rival factions of the Guelphs and Gibbelines. The Germans, in the last place, are equally zealous in carrying it back to the days of Henry

* To such a degree had these follies prevailed, that Father Menestrier complains very feelingly of the interruption which the meditations of pious readers must have received from the perpetual blazoning of the arms of St Gregory, St Augustine, &c. on the margin of prayer books, "Comme si l'on ne pouvoit pas assez pieusement lire une priere dans ces heures sans voir le blazon du Saint pere qui en avoit fait usage le premier."

the Fowler; and think they have sufficient evidence of the justice of their opinion, in the accounts which have come down to us of the ancient tournaments of Germany. The truth is, that it is by no means an easy matter accurately to ascertain the origin, or trace the progress of things which derive their authority from chance and the insensible influence of custom, rather than from reason and the positive institutions of legislators.

4. It is quite evident, that painted shields and military ensigns of some sort, are coeval with the art of war itself. Jews, Egyptians, Greeks, Romans, and Barbarians, must all have made use of some tokens, by which the warriors of the same nation might distinguish each other in battle. But there seems to be little reason for doubting that these people were familiar with the use of simple devices alone, or fanciful figures, which were not intended either to distinguish one family from another, or to mark the nobility of those who bore them. So little, indeed, is their nature ascertained, that the same things have been taken indifferently for devices, for emblems, for hieroglyphics, for symbols, and for armorial bearings, as may easily be seen in the treatises of Pierius, of Minos, of Ruscelli, of Bargagli, of Vulson de la Columbiere, and of Father Caussin, who all contrive to twist the same facts into evident testimonies of the truth of the most inconsistent theories. The dove of the Assyrians is, according to all the interpreters of the Scriptures, a figure of Semiramis. Yet this same dove is with Pierius a hieroglyphic, with Alciatus an emblem, with Bargagli a device, with Caussin a symbol, and with M. de la Colombiere a coat of arms. The error of all those who maintain the high antiquity of heraldic bearings seems to have arisen from the circumstance, that a few instances have been preserved by the poets and historians, in which these personal devices had, from some extraordinary causes, become hereditary and transmissible.

5. Aventinus, descended from Hercules, carried a hydra on his buckler; and one of the Corvini is mentioned by Silius Italicus as having the raven of his ancestors for his crest. In Ovid, Egeus recognizes his son Theseus by the marks of his family on the pommel of his sword. Hypolitus carried, in the same manner, the marks of his birth; and the children of Jason and Hypsipilus bore as their device the ship of the Argonauts. See *Æneid*, 7.

> ——Victores ostentat equos satus Hercule pulcro
> Pulcher Aventinus, clypeoque insigne paternum
> Centum angues, cinctamque gerit serpentibus Hydram.

See also *Sil. Ital.* l. 5.

> Corvinus phæbæa sedet cui casside fulva
> Ostentans *ales* proavitæ insignia pugnæ.

Ovid *Metam.* 7.

> Cum pater in capulo gladii cognovit eburno
> Signa sui generis.

Seneca in *Hypolito.*

> Regale parvis asperum signis ebur
> Capulo refulget gentis Actææ decus.

6. In like manner, we meet with marks of *dignity* among the ancient writers, the "χξυσεος επι της πελτης αετος," was the well-known cognisance of the Median and Persian kings. (Xenophon's *Hellenics*, l. 1.) All these authorities shew that there were figures on the bucklers of the ancients, on the guards of their swords, on their helmets, their standards, and their cuirasses; but they by no means prove that these figures were armorial bearings in the technical sense of the word. The hereditary nature of some of their bearings, merely shews the anxiety of superstitious men to trace themselves to the lineage of the gods; as for instance Coraxes, who made his soldiers bear a thunderbolt on their shields, because he believed himself descended from Jupiter. The verses of the poets whom we have cited, prove nothing more than that certain warriors adorned their shields, and the pommels of their swords, with certain images representing the great actions of their ancestors.

A gentleman who should preserve the cavalry-horn which had been carried by his father in some celebrated war, might call it *insigne paternum*; or if it had belonged to his great-grandfather, he might call it *pro-avitæ insignia pugnæ*, and yet all this might have nothing in common with the family arms. Chryxus carried on his shield a representation of the siege of the Capitol, and the Gauls weighing the gold of the Romans, to shew that he was sprung from Brennus.

> Ipse tumens atavi Brenni se stirpe ferebat
> Chryxus et in titulos capitolia capta tenebat
> Tarpeioque jugo demens et vertice sacro
> Pensantes aurum Celtas umbone ferebat.
> *Sil. It.* 4.

Yet who would think of asserting that the Capitol, and Gauls weighing gold, were the armorial bearings of Chryxus? Whoever maintains this, must admit that all the images and figures of ancient casques, cuirasses, and shields, were armorial bearings in the same manner as these, and he will find not a few who bore the whole history of a country, or a few dozens of the metamorphoses, for their blazon. It seems evident then, that all these authorities prove nothing concerning the origin of heraldic bearings, more than they do concerning that of emblems or of devices; because the signs of which they make mention do not appear either to have been fixed in their forms, or of any determined colour, or universally hereditary. The far greater part appear to be the mere fictions and ornaments of poetry; such as the chimera on the casque of Turnus; Io changed into a cow; Argus who watched her; and Inachus with his urn, from which a stream descended on his buckler. *Æn.* 7.*

7. The pretended arms of the tribes of Israel are entirely the reveries of the Rabbins of the later times, who have amused themselves with imagining these figures, on the authority of certain allegorical expressions of which Jacob made use, to predict to his children the fortunes of their descendants. They assign to the tribe of Judah a lion, because he said to one of his sons, "Judah is a lion's whelp; from the prey my son thou art gone up," &c. *Gen.* xlix. 9. And to that of Zabulon an anchor, on account of this prophecy, "Zabulon shall dwell at the haven of the sea." *Gen.* xlix. 13. And as they have not been able to find any thing very appropriate for Reuben in the malediction of his father, they blazon for him the mandrakes which he presented to his mother Leah.

To say nothing of the evident absurdity of all this, the authors in whose writings these bearings are mentioned are

> * At levem clypeum sublatis cornibus Io
> Auro insignibat, jam setis obsita, jam bos
> Argumentumq. ingens, et custos virginis Argus
> Cælataque amnem fundens pater Inachus urnâ.

very far from being consistent among themselves. Some give to Dan an eagle, others a serpent, and some an eagle choking a serpent. Barnabas Moreno de Vargas, indeed, blazons all the tribes of Israel in a manner different from what has been mentioned above; as, "Los de tribu de Reuben porque su padre lo comparo al aqua posieron por armas unas ondas de aqua: Los de Zabulon pusieron una nave," &c. *Discurs.* 18. *De la Noblez.*

8. Neither does there appear any greater certainty among the Greek writers. Ulysses, in Lycophron, carries a dolphin on his buckler, and is accordingly styled δελφινοσημος; but Homer assigns to him the figure of the giant Typheus. Agamemnon, in the Iliad, carries the gorgon's head, but, in Pausanias, the head of a lion; and elsewhere we find him described with one dragon on his helmet and three on his shield. As for the celebrated shields of the seven chiefs against Thebes, it is rather amusing to find, that, after all the many arguments which have been founded on the accurate account of them in Æschylus, that great poet does not coincide, in any one particular, with the equally minute and laborious description of Euripides.

Even when the authors are perfectly consistent, the utmost that can be made out of their report is, that these warriors bore certain emblems, which may perhaps have had some mystical meaning; but can never be proved to have been marks of noble birth, as our armorial bearings are, even though some of them may have passed from father to son; otherwise we must believe, on the credit of Suetonius, that the Domitian family carried a *beard or* for their arms; because the historian, in order to mark that a red beard was a common feature in that family, says—"Quod *insigne* mansit et in posteris ejus, et magna pars rutila barba fuerunt." (Sueton. *in Nerone*, c. 1.) And yet nothing can be more certain, than that passages in ancient authors, of a complexion exactly similar to this, are the only authorities for half the *armorial bearings* of the Greeks and Romans. Because Seleucus had a mark on his thigh which resembled an anchor, he and all his descendants are said to have borne an anchor for their arms. It is wonderful that Augustus is not alleged to have blazoned on his shield the Ursa Major, since it is well known that he had on his back as many moles as there are stars in that constellation, and arranged in the same manner: (Sueton. *in Aug.*) The figures on the legionary shields of the time of Augustus were exactly of the same nature with those of the Greeks of the heroic ages, or of the Egyptians, Anubis and Macedo. And, upon the whole, if we lay aside the dreams of enthusiastic heralds, and scholars equally enthusiastic, who will not condescend to allow to the moderns the honour of inventing even the arts which they themselves despise, we believe we shall find that to be the most rational theory which maintains, that armorial bearings were invented in the 10th century, perfected in the 11th, and have accordingly been for about seven hundred years only, in any part of the world, the distinguishing marks of families, and of noble birth.

9. In many parts of Europe, there remain tombs of princes, lords, and gentlemen of every degree, more ancient than the year 1000; and yet in no one of these can the smallest trace of armorial bearings be discovered. The most indefatigable antiquaries have explored Italy, Germany, Flanders, and the various provinces of France and England, without the least success; and have been obliged to confess, that neither in manuscripts, nor upon the gateways, and vaults of castles, nor upon the altars of the most ancient cathedrals, have they been able to find any thing more early than the well known arms of Varmond, Count of Vasserburg, on his tomb in the church of St Emeran at Ratisbon. He is represented as lying on his back upon his tomb, with a lance in his left hand, and on his right his shield without ornaments—"Coupé of argent and sable, and over all a lion, with this epitaph on the border of it: Anno D'ni MX. in die S. Leonis PP Dnus Varmundus nobilis comes de Vasserburgh qui huic monasterio dedit Hofmarchiam in Vogterrerent hic sepultus." There is even some reason for suspecting, that this tomb has been rebuilt by the religious of the abbey. All the tombs of the 7th, 8th, and 9th centuries, have simple inscriptions with the image of the deceased. The greater part of those of the 10th and 11th centuries also are without arms; and the practice of representing them on tombs does not appear to have universally prevailed till the 12th century. The first Pope who can be proved to have borne arms is Boniface VIII. of the house of Cajetano, whose escutcheon is in the church of St John Lateran, and in the vaults under St Peter's at Rome. The bearings of all the Popes before him are now ascertained to have been the inventions of Ciaconius, Antonio Cicarello, and Gian Baptista Cavalieri. Coins before the year 1200 have no arms. The seals of princes and kings before that time bear nothing more than their effigies, and those of bishops and chapters representations of the tutelary saints of their churches; as, for instance, those of the Popes, which bear commonly on the one side the heads of St Peter and St Paul, and on the reverse the name of the pontiff.

10. If, before these times, the figures on bucklers had been hereditary and fixed in so many families, why happens it that the sons of so many heroes never carried the devices of their fathers, and the glorious marks of their illustrious achievements? Whence comes it, that when notice is taken of Helenor being introduced in the 9th Æneid without any ensign on his shield, a sufficient answer is supposed to be given, by saying, that young men, who had as yet done nothing illustrious, carried shields without ornament? Could they not then, as at present, carry their father's bearings? The truth is, these marks were altogether personal, or else common to all the individuals of a military corps.

> Cuncta phalanx insigne Jovis, cælataque gestat
> Tegmina, dispersos trifidis ardoribus ignes.
> *Valer. Argon.* 6.

And it was on account of this latter character that they received from the Greeks the appellation of δείγματα.

It may however be alleged, (and M. Court de Gebelin has laid much stress on the circumstance,) that there are many cities, the armorial bearings of which are to be found on monuments of very high antiquity; as, for instance, those of Rome, which we every day see represented on so many basso relievos, or those of Nismes, which are so common on the reverse of medals. To this it may be answered, that these cities have, within the last seven or eight hundred years, framed for themselves armorial ensigns out of their ancient devices, and that, before that time, no examples can be found of these marks being placed on escutcheons. S. P. Q. R. was the device of the Romans; but not, as in the present day, disposed *secundum artem* on a band falling down between two fillets. The crocodile attached to a palm-tree was the ensign of Egypt conquered, which the people of Nismes put anciently on their coins, with these words abridged, *Col. Nem.*; and, accordingly, the modern city blazons the same on its public edifices. We by no means assert, that no kingdoms or republics had fixed devices before the use of armorial ensigns: on the contrary, the eagle was a common device of the Romans, and composed part of their military standards; but they had also the dragon, the minotaur, the wolf, and the swine. The lion and the eagle have in every age been the symbols of royalty; because the one is the chief of beasts, and the other of birds.*

11. It is necessary to be at all times on our guard against the monuments of heraldry which are produced by our old writers as of a date prior to the 12th century. They are in general the inventions of silly monks, who had little else to do but to gratify their own vanity, and that of their benefactors, by these harmless fictions. Much contempt, indeed, has been thrown on the whole study, by the detection of the gross absurdities which they contain, and by none more than those of the celebrated Chronicle of the Priory of Ely, long preserved in the college of the English Benedictines at Douay. In this MS. we are presented with the history of some chiefs of King Harold's army, who, after the defeat at Hastings, defended themselves for seven years in the isle of Ely. The conqueror, however, at length prevailed, and lodged 40 of his soldiers with the religious persons who had afforded an asylum to these obstinate warriors. Each soldier lodged with a monk; and the story is, that, on their departure, the brethren painted in their refectory the arms of their warlike companions, which are accordingly blazoned with great exactness on the margin of the MS. But, in spite of the zeal of Mathew Paris, the style of the writing, and also of the illuminations, is such, that the authenticity of this record has long been given up.

12. The art of heraldry, in truth, like every thing else of nature or of art, did not all at once spring up to perfection. Its beginning long preceded its universal practice, and its scientific arrangement. The ancient figures on shields, and military ensigns, were the first dawnings of the art. It may be said to have made its first regular appearance in the world at the times of the tournaments; and in all likelihood attained its utmost perfection in the period immediately following these military exercises. The name of Blazon which has always been given to this art, the form of the oldest escutcheons, the metals, the principal figures and divisions of the shield, the crests, the wreaths, the mantles, and the mottos of heraldry, all conspire to prove the general position, that the first practice of the art took place on occasion of the tournaments of chivalry. †*Blasen* is a German word, signifiying to *blow the horn;* and the reason why this name has been given to the description of armorial ensigns is, that anciently those who presented themselves at the lists of the tournament were announced by the sounding of the horn. The heralds, after having ascertained the nobility of those who offered themselves, blew the trumpet, in order to warn the marshals and their assistants, and then *blazoned* the arms of the aspirants; that is to say, that, after sounding the trumpet, they proclaimed with a loud voice the bearings of their shields. The *Rimes du tournay de Chavency*, (which took place in the year 1285.) written by Jacques Bretex, furnish an example of this usage.

Les trompeurs si trompoient
Et les Bachelers amenoient
D'armes si empapillonez
Que depuis l'heure que je fu nez
Ne vi a mongré, tel mervoilles
Un chevalier d'armes vermoilles
A cinq annets d'or in ecu.
Vi devant tous qui sans ecu
Vient a voir la premiere jouste
Comment qu'il soit ne coi qu'il couste
Si quier as autres qu'on luy doigne
Lors öi ecrier Chardoigne
Et puis Vianne a ces heraux,
Garcons glatir, huier ribaux
Chevaux hannir—tambour sonnir, &c.

In all the descriptions of jousts which Olivier de la Marche gives us, and in all those of the old romances, it is always expressly mentioned, that " les trompettes cornerent et furent faits les cris accoutumez." In describing the " Joustes de l'arbre d'or," he says, " si tost que Mondit Seigneur le Duc fut sur les rangs fut apporté le Blazon de M. le Prince d'Orange neveu de M. le Comte d'Armignac, et apres fut allé querre par le geant et par le Nain; fut par le geant presente, aux dames *et le Nain* sonna sa trompe." When the tournament was at an end, it was a common thing for the knights to hang up their arms and these horns in some church; and many still remain (or at least did within a century) attached to the great altars in the churches of Wirtsberg, Ratisbonne, Mayence, and Cologne, as Menestrier informs us, who saw them himself, and says that they were shewn by ignorant people, who understood nothing of their true nature, and contented themselves with asserting that they had belonged to Orlando, or some of the other heroes of the court of Charlemagne.

When any combatant had once made his appearance at these tournaments, which seem to have been originally held every three or four years in Germany, it was no longer necessary for him to make any proof of his nobility, this having been already sufficiently recognised, and *blazoned;* that is to say, announced by sound of trumpet by the heralds of the lists. The persons who had attained this distniction commonly carried two trumpets by way of crest, in order to mark that they were *gentlemen*, recognised and *blazoned;* and thus when the bearings of shields began to be more fixed than before, many families retained these crests of trumpets. Helmets adorned in this manner are called by Dlugossius and Simon Askolski *Galeæ Hastiludiales*, that is, helmets of tournament. (See Plate CCXCI. Fig. 1.) Many authors, indeed, explain these trumpet figures to be the trunks of elephants. But if there could remain any doubt on the subject, it would be removed by observing that those who still retain these crests, are the very families whose names occur in the ancient tournaments, as those of Bavaria, Saxony, Brandenburgh, Lutzelstein, Mecklenburgh, Swartzenberg, Die Lobl, Noppen, Talheim, Romersheim, &c.

To blazon, by a gradual transition, came among the French who had borrowed it from Germany, to signify every sort of description. Thus Jacques de Fouilloux, in his book on hunting, which he presented to Charles IX. makes in four lines what he calls the " Blason du lievre."

Lievre je suis de petite stature, &c.

Favin uses it as synonymous with "to praise," page 439. " Les habitans disent pour blasonner leur ville, &c." But we elsewhere meet with it taken *in malam partem*, as in the Chronicle of Louis the first Duke of Bourbon, where he is said, in conferring the order of the crown on his knights, to have ordered them to honour the ladies, and not to permit any one to speak ill of them—" *blasonner et mesdire.*"

* Pausanias describes the shield of Agamemnon as bearing a lion's head, with the motto, " ουτος μεν φοβος εστι βροτων ὁ δ' εχων Αγαμεμνων." *A lion crowned* is in like manner ascribed to Dieterick and the other heroes of the Sagas.

† It is proper to mention, that many are of opinion that the word *blazon* is of Oriental origin; and in the Arabic Dictionary of Gieuharis, we certainly find the word *Bladzon* with two significations, 1st, " Gens, famille, maison;" 2d, " Insignia, armoiries, symles d'une maison."—But we cannot help looking on this as merely a casual coincidence, and imagine few will deny that the German root offers so very natural a derivation, that it is ridiculous to look farther.

The word has the same significations among the Spaniards, who make it signify still farther glory itself; as in Rodrigo Mendez Sylva *Poblacion*, page 7. "Sivra sobre todo de Blazon, aver procreado al memorable cavallero Quinonez." Nothing can be more simple than the analogy by which all these meanings are derived from the primitive *blasen*. Nor is it at all to be wondered at, that the French should have borrowed this term of art from Germany, since it was in that country that the first regular tournaments were held by order of Henry the Fowler, who was either the original institutor, or at least the restorer, of these and many other exercises for the young nobility of his empire.

13. The form of the ancient escutcheons is a second proof of this origin of armorial ensigns; for they are always represented as lying on the one side, and tied up by small strings, exactly as the shields of the jousters were attached to the lists, or to the neighbouring houses, which they called "faire fenestre." They are so represented in the celebrated "Tournay de la Garthuse," in the National Library at Paris. They are also hollowed out on the right side for the reception of the lance, as may be seen in all the old monuments of the churches in Germany and Italy. From the tournaments, in like manner, is derived the custom of joining the shield and the helmet, to compose the complete armorial bearings; because they were so arranged in some cloister or public place a few days before the jousts, that the ladies might have an opportunity of seeing them. All these observations are verified by the curious treatise of René of Anjou, King of Sicily, which is printed in the Miroir de la Noblesse, by M. Vulson de la Colombiere. "All you princes, lords, barons, knights, and esquires, who intend to tilt at this tournament, ye are ordained to lodge yourselves in the city four days before the tournament, to make display of your armories, on pain of not being received at the said tournament; and your arms shall be thus. The crest shall be placed on a plate of copper large enough to contain the whole summit of the helmet, and the said plate shall be covered with a mantle, whereon shall be blazoned the arms of him who shall bear it; and on the said mantle, at the top thereof, shall the crest be placed, and around it shall be a wreath of colours, whatsoever it shall please him." "Moreover, when all the helmets are set in order after this fashion, then shall all the ladies come, and the damsels, and the lords, knights, and esquires, who shall visit them in their order, from the beginning to the end. And the judges who shall be there shall lead the ladies three or four turns, to see them well, and to examine the crests; and the herald shall set forth unto the ladies to whom this ensign pertaineth, and to whom that; and if there be any one which belongeth to any reviler of the ladies, the ladies shall touch his crest, and on the morrow it shall be sent away, and he shall have no tilting at this tournament. *Traité de la forme et manier des tournois a plaisance*, &c. *Miroir*, p. 56.

14. The colours which enter into the composition of armorial bearings are, by many authors, said to be no other than those of the ancient games of the Roman circus, which passed into the tournaments of the Gothic nations. The different factions of the hippodrome were distinguished by their colours of white, red, blue, and green. To these Domitian added yellow; and the only remaining tincture, viz. black, might be easily introduced by those chevaliers who were in use to frequent tournaments in habits of mourning, on occasions of particular distress. Thus King René of Anjou, after the unfortunate war of Naples, went to the tournament of "La gueule du Dragon," in the year 1446, clothed in complete suit of black armour, "his shield sable, semee de larmes, and a black lance in his hand."

The partitions of the shield are in like manner supposed to be deduced from the habits of tournaments, which were frequently of different colours, sometimes the one side of the garment differing from the other, sometimes the top part from the bottom, &c.; a relic of which custom may still be observed in the dresses of many provincial magistrates on the continent. From the barriers and lists, and their various parts, are taken the forms of the pale, the chevron, and the saltier. The ring or annulet is derived from the common reward of the victorious cavalier. The bend and the fess from the scarfs which the combatants wore, and which were often the gift of their ladies, as we read in the romances, the wreath and other ornaments of the helmet, are all connected with the same custom. The lady herself took care to adjust these parts of her knight's equipment, which were generally of *her colour*; and are accordingly known in the romances by the names of "faveurs des dames," "atours de dame," &c.

15. With tournaments, it is probable that the art of blazonry passed very soon into France. Many of the figures, indeed, were never introduced into the heraldry of that or of any other country, and remain at this day peculiar to Germany alone. If armorial bearings, however, were first used in Germany, it must be confessed that the French were the first to reduce the method of using them to rules. Accordingly, the only other nations which have made any progress in the art, viz. the English and the Scotch, make use of French terms. The Italians and Spaniards know nothing of the matter; and the attainments of the Germans themselves, are frankly admitted by Spenerus to be altogether contemptible. Sir Henry Spelman says expressly, that the gentry of England had no coat-armour till the time of the Norman conquest; and treats with the utmost derision the fables and reveries of those, who assign arms to the Danes, Saxons, Britons, and the pretended knights of the Round Table. The princes of Anjou, in all probability, introduced the custom into the kingdoms of Naples and Sicily, as may be seen in the treatises of Scipione Ammirato and Philibert Campanili. But although the practice of using armorial bearings may have been considerably extensive before the period of the Crusades, there can be no doubt, that these celebrated expeditions must have been at once the means of rendering their use universal among all the European nations, and at the same time of making the figures more fixed, and consequently the blazonry more scientific. Arms, it is probable, completed their hereditary character from the piety of children, which must have led them to adopt, with religious respect, any temporary devices borne by their fathers in these holy wars. The cross soon became the most common of all bearings, and its form was varied beyond every conception by the ingenuity of the heralds.

16. The heraldic writers who approach most nearly to each other, in their opinions respecting the origin of armories in general, are yet much at variance concerning the precise time of their introduction into England. It is needless to refute the statements of such writers as Stow, who can tell us gravely, that "Brute, after a long and wery journey with his Trojans, passing thorow France, building the citie of Toures, arrived in this isle, the which was then called Albion, at a place called Totness, in Devonshire, *bearing gules, two lions golde rampants a contrarie, also a bannar of Vert, a Diane of gold fichele crouned and entronised.*" Edmonstone is of opinion, that armories were probably first used in England by King Edward the Confessor, and afterwards more plentifully practised by William the Norman and his nobles. Camden, however, is inclined to think them of yet later date with us, and says, "that shortly after the Conquest, the estimation of arms began in the

expeditions of the Holy Land, when it was accounted an especial honour to retain those arms which had been displayed in the Holy Land, in that holy service against the professed enemies of Christianity, and that we received at that time the hereditary use of them; but the same was not fully established until the reign of King Henry III.; for that in the instances of the last Earls of Chester, the two D Quinceys Earls of Winchester, and the two Laceys Earls of Lincoln, the arms of the father still varied from those of the son." Sir Henry Spelman is of opinion, that arms are of a yet more modern growth in England, and says, "there is little reason to be confident in matters of pedigree and arms much beyond four hundred years," adding, "that he has his doubts as to their being entitled even to that antiquity. *Nescio an ea prorsus antiquitate.*" The period of their introduction into Scotland, must of course have been nearly the same with that of their first practice in England.

17. The custom being once fairly introduced, it is by no means difficult to see from what causes the great variety of the figures of heraldry must have arisen. Great events, or illustrious actions; the peculiarities of local situation; the partialities for particular employments, offices, dignities, and the spirit of devotion; the nature of fiefs, and the vestiges of ancient devices, factions, pilgrimages, and tournaments, must all have suggested to individuals the bearings which they adopted. Nothing, however, appears to have given occasion to more armorial ensigns, than the names of persons or of families. In every nation of Europe the effects of this practice are still abundantly apparent; yet we have no doubt the evidence would have been infinitely more striking, but for the many changes which have taken place in the names of families since the fixing of their arms. Many authors, it is true, treat with ridicule arms of this sort; but it is sufficient to observe, that Spelman, Menestrier, and Gebelin, are of a different opinion. The last indeed expressly says, that he has no doubt the armes parlantes are the most ancient of all. The original bearers of these arms, it is probable, thought their names so illustrious, that they could adopt no better means of making themselves known than devices, which would suggest these names to the beholder. Accustomed as they were to shout their names in combat, and hear them proclaimed at the tournament, it was a very natural thing to paint them on their surtouts, their shields, and the caparisons of their horses. There are very few families, whose names retain any meaning, which have not framed to themselves arms in some respect alluding to that signification. The instances of arms of this kind in our books of heraldry are innumerable. The Bollens, in allusion to the first syllable of their name, carry *argent* a chevron gules *between 3 bulls heads sable*. Pope Adrian IV. (whose proper name was Nicolas Breakspeare,) bore gules a lance broken argent. The illustrious family of the Lamberts bear 3 lambs argent; and the practice is equally evident in the bearings of the Lovets, the Bores, the Swineys, the Swintons, the Swallows, the Grifins, the Metcalfs, and the Starkeys; of Bowes, Cockayne, Dove, Askew, Arondel, Ravenscroft, Buikley, Heron, Beeston, Bird, Horsey, Cheval, Colt, Capraville, Quatremains, Borlase, Troutbec, and Godolphin. In France, the names of Ailly, Mailly, Crequy, Rubempré, Castelnau, Chabot, Gougeux, Hautefort, De la Tour, De Pontevez, De Porcelet, and De Retel, are among the most distinguished of the kingdom. Nor are their bearings a whit more significant than those of the great Italian families of Colonna, Ursini, Frangipani, Anguillara, Sanctacruce, Spinola, Cicala, Barbarigo, Negroni, &c. or of the Spanish houses of Luna, Solis, Zapata, Acuna, Quixada, Torres, and Cardona.

There are several ways in which arms may bear a relation to names. 1st, By the simple cypher or initial letter of the name; as is the case in the arms of many towns on the continent, and of the families of Montenegro in Spain, who bear an M crowned, and Awensberg in Germany, who bear an A, &c. 2d, By the representation of objects, either natural or artificial, which express the sound of the name: as the ancient sovereigns of Dauphiny and Auvergne bore a dolphin on their shield; the city of Lyons a lion; that of Berne a bear, &c. 3d, By things which have some likeness to the name: as the Chevriers, who bear a cheveron; the Gouviers, who carry a wolf's head, &c. 4th, By things which have some relation to the signification of the name: as Archer, who carries three arrows; Falconer, falcons: Diane, a crescent; Riddell, ears of rye. The family of Law in Scotland have a cock in their arms, in allusion to the common method of expressing the cry of that bird among the Scotch, "*Cocky-leery*-Law." 5th, There are arms which express the name by way of *rebus*: as *Richarmes*, three casques crested with crescents *or*; Gantelmi at Naples, a glove and a helmet, &c.

Many of these allusions are very far-fetched and absurd; perhaps none more exquisitely so than that of the Paravasini in the country of the Grisons, who bear a goose, because, says Menestrier, that bird has "some resemblance to a swan *par avis Cycno*." It is worthy of remark, that long before the science of heraldry existed, the ancients, in their marks and devices, affected this sort of resemblance of figures to names. Thus the reverse of a medal of L. Aquilius Florus bears a flower; the Rhodians had a rose on their coins; and the Delphians a dolphin. On the medals of Voconius Vitulus we see a calf; on those of L. Thorius Balbus a bull; and a man's foot on those of L. Turius Crassipes.

18. To commemorate any events of a marvellous and unexpected nature, is another very common object of armorial bearings. There is no point, however, connected with heraldic pursuits, in the investigation of which we must advance with greater caution than here. The absurd vanity of particular families has been the foundation of so many idle inventions, that it is difficult to avoid classing with these matters of a very different nature. As an instance of the species of arms to which I now allude, it is sufficient to mention the *three birds* of Lorraine, which are said to take their rise from the circumstance of Godfrey de Bouillon's stringing three birds on one arrow. Important discoveries and illustrious actions have been in all times celebrated in the same manner. Thus, after Columbus had returned to Spain from the discovery of the new world, he was allowed by Ferdinand and Isabella to bear under a chappé of the arms of Castille and Leon, in a sea of *Argent* and *Azure* five isles *or* with the motto, "A Castilla y a Leon, Mundo nuevo dio Colon;" which bearings still remain with his descendants of the houses of Veragua and Xamayca.

The Maid of Orleans, when she took arms against the English, carried on her banner a sword surmounted by a crown. This, with the addition of a fleur-de-lys, the king of France afterwards assigned as arms to her brothers, who were ennobled, by letters patent, in the year 1429, and took the name of du Lys. The house of Colonna, in Italy, have around their shield the 14 standards taken from the Turks in the famous battle of Lepanto by Marco Antonio Colonna, General of the forces of the Pope. The Douglasses of Scotland bear a bloody heart crowned with a royal crown, in memory of the good Sir James Douglas, who died on his way to the Holy Land, whither he was conveying the heart of King Robert the Bruce. A badge of the same species was assumed by the Earl of Surry, in the year 1515. "A silver lion (the old cognisance of his family) tearing in pieces a lion prostrate gules.

> "If Scotland's coat no mark of fame can lend,
> That Lion placed in our bright silver bend—
> Which as a trophy beautifies our shield
> Since Scottish blood discoloured Flodden-field,
> When the dark Cheviot our proud ensign bare,
> As a rich Jewel in a lady's hair, &c."
>
> *Drayton.*

Nicolas Upton mentions an English gentleman who assumed Argent, three ox heads sable, "pro eo quod ipse erat in bello Vernolii cum lancia per membra genitalia totaliter transfixus, sic quod amplius generare non potuit." (*De Milit Officio*, p. 154.)*

The influence of the spirit of faction has also given rise to innumerable bearings. In Italy, during the contests of the Guelphs and Gibelins, things came to such a pass that almost every family was obliged to adopt some method of expressing by their arms to which party they adhered. The Guelphs carried Coupé, the Gibelins party. The Guelphs bore the lily of Florence gules on argent; the Gibelins argent on gules. The fleur-de-lys-in-chief (after the Guelph party had embraced the cause of Charles of Anjou), became a Guelph mark,—and three stars in chief denoted a Gibelin. In France, in like manner, when the kingdom was split into two factions from the year 1409 till 1449, those who espoused the cause of Orleans and Berry, carried a white bend, and were called "bendes," while the adherents of the Duke of Burgundy were known by the cross of St Andrew.

19. Offices of dignity are marked in the same way. Thus the great officers of the empire were all accustomed to bear the tokens of their dignity. The Counts of Oldenburgh, as architects of the empire, gules *two fesses or*, which are supposed to represent two beams. The house of Wirtemberg bore three stag-horns. That of Wernigerode a fish; and the Electors of Hanover the imperial crown, as archtreasurers of the empire. When any great family had once assumed a particular bearing, it was very natural for their vassals to bear it, either in whole or in part, as a token of their dependence. Indeed, the grants of feudal tenure were commonly made with some such condition. Thus in Brittany almost every family bore Ermine in honour of the ancient sovereigns of that country; and a great many mascles, and billets, in token of their connection with the houses of Rohan and Beau Manoir. In Cheshire sheaves of wheat are very common, and these were the bearings of the old Earls of Chester. A striking instance of this custom is to be met with so late as the time of Edward III. in the case of the four esquires of Lord Audley, who all adopted the bearing of that nobleman, with some little variation. (Vide Spelman's *Aspilogia*, p. 49.) And there is preserved in the notes on the same treatise, a charter, by which Sir Gervase de Clifton makes a similar grant of a helmet to his well-beloved friend Richard de Bevercotes, dated in the third year of Richard II. In Scotland many old families bear stars in those parts of the country where the Douglasses were most powerful. And a large proportion of the families of Renfrewshire bear their figures chequered, in honour of the house of Stuart.

The ancient signiory of the castle of Tunbridge, in Kent, belonged to the Clares, Earls of Gloucester, who bare for their arms *or, three chevrons gules*; and therefore the family of Hardress bare *gules, a lion rampant ermine debruised by a chevron or*, to denote that they held their manor of Hardress by knight's service of the said castle of Tunbridge.

20. Soon after arms had acquired the reputation of being the avowed and established marks of gentility, they came to be looked upon as inheritances alienable. So that although no man could legally assume at his own pleasure the coat-armour which had been granted *per expressum* to another person by the king, yet it was generally supposed that the original grantee or proprietor had, as it were, an absolute freehold in his *arms*, as well as in his lands, and might with equal right transfer the property of either to another person. And accordingly instances are not wanting of the proprietors of coat-armour conveying and assigning by formal grants, and that with a covenant of warrantry, the original paternal ensigns of their own family, as well as the coat-armour of other families which had descended to them by intermarriages, to persons nowise connected with them by blood, *to the exclusion of their own heirs*. Although no doubt could have been entertained as to the truth of these facts, yet the legality of such concessions having been often called in question, it is proper to state that the matter was fully discussed in the court of the Earl Marshall of England, in the case which depended between Sir Thomas Cowgan and Sir John de Norwich, and in that between John Lord Lovell and Thomas Lord Morley.†

Latterly, however, it has been invariably held as indispensable, that arms should be either given or authorised by the prince. The concession of arms by the sovereign may be in the common way, viz. wherein the royal consent is given to the use of such and such arms, whether they have been formerly borne by the grantee or not, as it is expressed in the common words of letters of nobility on the continent of Europe. "In omnibus et singulis honestis expeditionibus, et actibus tam serio quam jocis nobilium, militarium armigerorum modo in tourneamentis hastiludiis," &c.; or the concession may be of a particular kind, by which the sovereign permits his subject to assume some honourable augmentation, often part of his own royal atchievement, in token of his peculiar favour. Thus the double tressure has been granted to several families in Scotland, as the Randolphs Earls of Murray, the Seatons of that ilk, &c.; and the lion, as to the Duke of Lauderdale by way of supporter. When Henry Duke of Brunswick came to England to visit his ally Henry II. who then bore five leopards *or*, King Henry gave two of them to be carried by the Duke, which are still retained by his descendants, and are marshalled with other figures in the fourth quarter of his present Majesty George III. Edmonstone gives at full length the deed by which Queen Elizabeth allowed the Duchess of Suffolk to "assume the arms of England and France quarterly within a border gobony gold and azure," "to be an apparent sign of her consanguinity." Arms granted in this manner are stated by Menestrier to be very common in every kingdom of Europe, and are in a proper sense distinguished by the name of *arms of concession*. We shall have occasion to take more particular notice of some of these bearings in the sequel. In the meantime, we proceed to consider in their order the signs of honour.

* "Ob hujusmodo causas insignia concedi satis magno est argumento scutum Coleonum gentilitium quod *icone trium testium* insignitur. Multi enim ex hâc familia tres testes habuisse perhibentur. Vide Aldrovandum de Monstrorum historia, Bauhinum de Hermaphroditis Kornmannum de Miraculis Viventium. Coleonum insignia ex vita Bartholomæi Coleonis huc transtulimus. Deditum fuisse amoribus Auctor satis ingenue confitetur. Et fidem rei fecerit illud evangelicorum ministrorum decretum quod triorchi cuidam apud Germanos principi permisit concubinam Uxori superinducere de quo videas Thuanum." *Note in Upton*, p. 57.

† See Anstis's *Register of the Garter*, vol. ii. p. 260.

*Of the Shield, Surcoat, and Ensign.*

21. These are called by heralds the three principal signs of honour, in as much as *arms* have been commonly placed on them. The *shield*, being always deemed to be a necessary instrument in the defence of the body, and an honourable badge, was judged by all nations the most convenient tabula to contain marks of valour and honour, and therefore it is considered as the most proper and principal of all the heraldic signs of honour. Historians furnish us with various forms of shields used by the ancients; but at the time when *armorial bearings* were first instituted in the way already described, and came to be considered all over Europe as *tesseræ gentilitiæ*, and hereditary marks of honour, shields, for the most part, were triangular, as may be seen on the most antique monuments, seals, &c.;* accordingly, the shield so shaped is called by the French the *ancien ecu*. From this triangular form came the custom in heraldry of putting the greater number of figures above, and the less below, as three, two, one. In subsequent times, a form of shield became more prevalent; square, rounded, and pointed at the end: these are most common in this island, and in France. The Germans make most use of the shield *chancre*, with bulgings and notches, derived from their tournaments. The Italians have mostly the oval shield. See Plate CCXCI. Figs. 1, 2, 3, 4, 5, 6.

The *surcoat* is a loose thin taffety gown, used formerly over armour, upon which the arms of the bearer were commonly painted or embroidered, that they might be distinguished in time of battle; a memorable instance of the use of which we have preserved in the history of the Chevalier Bayard. These surcoats were much like those now worn by heralds.

The third is the Ensign, under which general name are comprehended the varieties of Standard, Banner, Pennon, Gideon, and Gonfanon.

The first two are of a square form, bearing the whole achievement of such as have a right to them; which none hath under the degree of a *knight banneret*.

The *pennon* and *gideon* are of an oblong form, with a sharp point, and carry a part only of the owner's arms; as his device, crest, and motto.

The *gonfanon* is a banner of the church, square, but having three labels, or *fanons*, and the bearer thereof is called the *gonfaloniere*.

Arms have also been represented anciently on the furniture of horses, as in the seals of Alexander II. of Scotland, Edward I. of England, the two De Quinceys, Earls of Winchester, in Spelman, &c. See Plate CCXCI. Fig. 2.

Women place their arms on a lozenge, (See Fig. 7.) which is a square figure with one of its angles uppermost; or on a fusil, which is a figure of the same nature, but longer than it is broad. The old writers, particularly Sylvanus Morgan, in his *Nobility native, or Adam's coat*, are pleased to derive the common form of the man's escutcheon from the spade of Adam, and of the woman's lozenge from Eve's spindle; but, as Nisbet observes, "these things are mere fancies." Neither is he more pleased with the sentiments of Sylvester De Petro Sancto, who deriveth the lozenge from the cushion used in sewing, &c. *pulvillum in quo exercent mulieres linearia opificia.*

*Of the Blazoning of Arms.*

22. Blazon, or the art of blazoning of arms, consists in the knowledge of those colours, or metals, which are used in the art of heraldry, and of the several lines of partition, ordinaries, and changes, whereof the coat is composed.

*Of Tinctures.*

23. The colours and metals thus used are most commonly blazoned by tinctures, which have their proper and fixed terms taken from the French; which tongue has indeed, in consequence of the great excellence of the French heraldic writers, become, in some sort, the common language of heraldry among all the nations of Europe. The terms of these tinctures are these:

| | |
|---|---|
| *Or*, . . . . . that is . . . | Yellow. |
| *Argent*, . . . . . . . . . | White. |
| *Azure*, . . . . . . . . . | Blue. |
| *Gules*, . . . . . . . . . | Red. |
| *Sable*, . . . . . . . . . | Black. |
| *Vert* or *Sinople*, . . . . . | Green. |
| *Purpur*, . . . . . . . . . | Purple. |

1. *Or*. This metal is allowed to be the most honourable of all the tinctures. In Latin blazonry it is called, *aureus color*, *aurum*, *luteum*, *croceum*, *Galbinum*. It is known in engravings by small points or ticks. Fig. 8.

2. *Argent*. In Latin, *argenteus color*, *albus*, and *argentum*. To mark this colour in engraving the field is left blank. Fig. 9.

3. *Azure*. This is derived from the oriental *lazurd*, which signifies the heaven, or its colour. The Latins say, *cæruleus*, *cæsium*, *glaucum*, *cyaneus*. It is represented by horizontal lines. Fig. 10.

4. *Gules*, evidently derived from the eastern *gul*, or *ghul*, which signifies a rose, red, &c. In Latin, *color roseus*, *rubor*, *rubeus*, *sanguineus*, *coccineus*; marked in tallyduce by perpendicular lines. Fig. 11.

5. *Sable*, comes also from the oriental word which expresses the same idea, *zibel zebel*, still retained in the French, as *maitre zebeline*, *maitre noire*; marked by cross hatches, perpendicular and horizontal. Fig. 12.

6. *Vert*, the common French word for green. The French themselves commonly use *sinople*, a term, the origin of which has occasioned no small difficulty. Some think it is derived from the city of Sinope, in Asia, as if the earth there were green; others esteem it derived from the Greek πρασινα οπλα, green arms. This also seems to us to be of Oriental origin, *tsin*, herb, verdure; *bla*, blade: the young blade of grass, which is always of the most beautiful green. Indeed, our own word *green* expresses no other idea but that of *growing*. The latin writers say, *viridis* or *prasinus*. It is marked by diagonal lines from right to left. (Fig. 13.)

7. *Purpur*, is marked by diagonal lines from left to right. This colour is, by the best writers, little approved. Spelman talks of it as of new introduction in his time; and in Scotland it is entirely unknown, except among the *new gentry*, as Nisbet says. (Fig. 14.)

Besides these, the English heralds mention two other colours. 1st, *Tenny*, or orange; known, in engraving, by diagonal hatches from right to left, and *e contra* from left to right. 2d, *Sanguine*, or dusky red, marked by diagonal lines from right to left, and horizontal ones. These two colours are, by the English writers, appropriated to *abatements of honour*, and so are called dishonourable stained colours.

When any object is represented not in any of these heraldic colours, but as it is in nature, as, for instance, grapes, peacocks, &c. it is then blazoned *proper*.

* Spencer gives the Red-cross knight a shield of this form, *Fairy Queen*, 1. 6. 41. "And catching up in haste his three-square shield."

Some fanciful heralds, particularly in England, give out a rule, that gentleman's arms alone should be blazoned in the manner above mentioned, those of noblemen by precious stones, and those of sovereign princes by planets; thus,

| Tinctures. | Precious Stones. | Planets. |
|---|---|---|
| Or. | Topaz. | Soal. |
| Argent. | Pearl. | Luna. |
| Blue. | Sapphire. | Jupiter. |
| Red. | Ruby. | Mars. |
| Green. | Emerald. | Venus. |
| Sable. | Diamond. | Saturn. |
| Purpur. | Amethyst. | Mercury,&c. |

But these niceties seem to be entirely of a piece with the imaginations of another herald, who insisted on blazoning by *flowers*; as rose, jonquil, &c. or with the accurate definitions of virtues, &c. signified by particular tinctures, at one period so much in vogue: as *or*, faith; *argent*, innocency; *blue*, loyalty, &c. It is sufficient to observe, that not only is all blazoning of arms of different degrees in different manners unknown to the heralds of France, Italy, and Germany; but that the practice would tend to confound colours with charges, and the things borne with the colours. Moreover, it would render useless the great rule of not putting *colour on colour*, or *metal on metal*;* for this could not hold, were metals and colours no longer employed or named in certain armories.

### *Of Furs. Ermine. Vair.*

23. The use of furs in armories is in all likelihood derived from the habits and garments of military men and civil magistrates, according to the opinion of Sylvester De Petro Sancto, Nisbet, and others, though a different account of the matter is given by Sir George Mackenzie, The antiquity of their use is proved by the circumstance, that when Innocent III. commanded Conrad Bishop of Wurtzburgh, by way of penance, to go and fight against the Saracens, he particularly forbade him to appear in ermine, vair, or any colour employed in tournaments.

These furs, Ermine and Vair, are the principal furs employed in the heraldry of any country, and the only ones known in France or Scotland. Ermine is supposed to take its name from an animal of the same name, the skin of which has long been considered as a royal and noble ornament. In Great Britain, the different degrees of nobility are distinguished by the number of rows of ermine with which the mantle of the peer is trimmed; and Menestrier informs us, that at the coronation of Henry II. of France, for want of true ermines to line his robes, use was made of cloth of silver, spotted with patches of black velvet. This fur is represented in blazoning by a white field powdered with black spots, which spots have the point upward tipped with three ticks of black. (Fig. 15.) *Contre ermine* is that in which the field is sable, and the spots argent. (Fig. 16.) As for the English furs, *erminois* field *or* spots *sable*; *pean* field *sable* spots *or*; and *erminites* field *argent*, spots *sable*, *with a single hair gules at each side of the spot*, these are unknown in any other country.

Ermine and its kinds have two tinctures. The spots are in place of figures; and it may therefore form a complete *armory* of itself, as is the case with the arms of the Duchy of Burgundy. But ermine may also form a field, whereon every charge, either of metal or colour, may be placed; or it may form itself the charges, and be placed without impropriety upon any shield.

The spots of ermine are of an indefinite number, irregularly disposed on the shield; but any certain number of these under ten may be borne after the position of any of the heraldic charges. In this case, they are not to be blazoned *ermine*. The spots being in truth charges, are called by us *ermine spots*; by the French *mushetours*; and in the blazon their number and disposition must be expressed. The Latins call them *maculæ* muris *armeniæ*.

Vair is the other principal fur in heraldry. From what its name is derived seems perfectly uncertain. The Latins certainly blazon it, "Arma variata," &c. Its pieces are always *argent* and *azure*, disposed in the manner of rows of little figures, resembling shields or bells, so placed that the point of the bells in the second row is between the base of those of the first. (See Fig. 17.) The *grand-vair* of the French is that wherein the rows of these figures are only three in number. In *menu vair* the rows are above four, and this is the common *vair* of our heraldry. For *countre vair*, see Fig. 18.

The species of fur represented in Fig. 19. which consists of pieces alternately arranged of azure and argent resembling cups, goblets, &c. is variously named *meirre*, *vairy cuppy*, *vairy tassy*, or *potent contre potent azure et argent*. Potent is derived from *potence*, a *gallows*, the top of which these figures are supposed to resemble. These furs may all be used in the same manner as the ermines.

### *Of the Points of the Shield.*

24. For the convenience of blazoning, the different parts of the shield have received particular names, taken from the parts of the human body; of these a scheme is given in Fig. 20. ABC represents the highest part of the shield, which the French called *chef*, and we *the chief*. D is called *the collar* or *honour point*, because badges of honour are worn on the breast, as those of the garter, thistle, &c. E is called *the cœur point*, as also the *centre* or *fess point*. F, *the nombril*, or *navel point*. GH, by the French, the *flanque points*, by the English, the *base points*. I, the base point. A is the *dexter chief point*, or *canton*. B, the *middle chief point*. C, the *sinister chief point*. G, the *right base point*. H, the *sinister base point*.

When arms are blazoned without relation to, or expression of, the point wherein the figures are placed, they are then supposed to occupy the centre of the shield. When figures are ranged as ABC, they are said to be *in chief*. When ranged so as to reach from the dexter chief point to the sinister base point, to be *in bend*; from the sinister base point to the dexter chief point, *in bend sinister*; when placed between the base points, they are said to be *in base* or *in point*.

* The rule alluded to is thus traced to its origin by Feron, in that part of his work wherein he treats of the armorial bearings of Adam. "Telle couleur de rouge est attribuée à notre bon pere Adam, qui porta pour armes de gueulles seulement auquel commenca noblesse, et qui en langue ebraique signifie rouge. Aussi fut il formé de terre au champ de Damascene. Les quelles armes il ne porta longuemente, transgressant le commandement de Dieu; et lors furent chargées d'une pomme de sable, demonstrant le vilain peché par lui commis contre la puissance divine en trangressant son commandement. Qui est le motif que nos predecesseurs ont tenu pour maxime cester eigle generale, que *armoiries sont faulses ou couleu domine autre couleur*, qui à este observée jusques a present."

Vide *Not. in Uptonum*, p. 39.

*Of the Lines of Partition.*

24. The field or surface of the escutcheon is divided into parts by various lines.

1. A plain horizontal line.
2. An angle.
3. A Bevile.
4. Escartele.
5. Nowy.
6. Arched, or enarched.
7. Double arched.
8. Wavey, or undé.
9. Invecked.
10. Ingrailed.
11. Battled, embattled, or crenellé.
12. Battled, embattled.
13. Nebule.
14. Potent.
15. Indented.
16. Dancetté.
17. Patte, or dovetailed.
18. Urdé.
19. Rayed, radiant, rayonné, ráyonated.
20. Raguly.

It must be observed, that indented and dancetté are lines of the same form, differing, however, in the size and number of the cuts or indents; those of the former being more numerous and smaller than those of the latter. For example, a Fess *dancetté* should be composed of three indentations and no more, whereas the Fess *indented* may have double that number. These lines are all engraved in Plate CCXCI. from Fig. 21—Fig. 40.

When a shield is by a horizontal line divided into two equal parts, it is said to be *coupe*, or *parted per fess*. See Fig. 41.

When a shield is by a perpendicular line divided into two equal parts, it is said to be *party*, or *party per pale*. See Fig. 42.

When a shield is divided into two equal parts by a diagonal line drawn from the dexter point chief to the sinister point base, it is said to be *tranché*, or *party per bend dexter*. See. Fig. 43.

When it is so divided by a diagonal line from the sinister point chief to the dexter point base, it is said to be *taillé*, or *party per bend sinister*. See Fig. 44.

When the partition line is straight, as in Fig. 21. above mentioned, it has then no additional denomination in the blazon. But if it has any of the other twenty forms, then the term of that form must be added in the blazon, and is of frequent use for the distinction of cadets.

When the first two lines, *parted per pale*, and *parted per fess*, (in French *coupé* and *parti*,) meet in a field, they divide it into two equal parts, or quarters, which are of different tinctures, the first as the fourth, and the second as the third. Thus we say, *quarterly gules and argent*: the French, *ecartile de gueules et d'argent*; Gerard Leigh and his followers, *parted per cross*. See Fig. 45.

When tranché and taillé meet in a field, they divide it into four areas, which is blazoned *parted per saltier argent and azure*. The French would say *d'argent flanque d'azure*, or *L'ecartile en sautoir*. See Fig. 46.

When coupé, tranché, and taillé meet in a field, they make six triangular areas-blazoned *girony of six*. Fig. 47.

When the whole four lines, coupé, party, tranché, and taillé, meet in one field, they divide it into eight conal parts blazoned *girony of eight*.

When two half diagonal lines, rising from the dexter and sinister points base, meet in the collar points, it is *party per chevron*. See Fig. 48.

When a shield is divided into three equal parts, it is said to be *tierce*. See Fig. 49.

| | |
|---|---|
| If by perpendicular lines, | *tierce per pale*. See Fig 49. |
| If by horizontal lines, . . . | *tierce per fess*. See Fig. 50. |
| If by diagonal lines from right to left, . . . . . . . . . | *tierce per bend dexter*. See Fig. 51. |
| If by diagonal lines from left to right, . . . . . . . . | *tierce per bend sinister*, or *tierce en bar*. See Fig. 52. |

Repartition lines, are those by which the shield is divided into unequal parts, as *coupé my-partée*, and *party-my-coupée*. See Figs. 53 and 54.

*Of the Figures of Heraldry.*

25. These are either peculiar to heraldry, and derive their names from it, and therefore called *ordinaries*; or they are things natural or artificial, used in armories, but retaining their own proper names; these are *charges*, properly so called.

I. *Of Ordinaries.*

All ordinaries are composed of some one or other of the above-mentioned lines. and are in number 19, according to the English heralds, viz.

1. The Chief, which is formed by one line only drawn, horizontally across the face of the shield, so as to separate the third part of the escutcheon from the rest. See Plate CCXCII. Fig. 1.

2. The Pale, which is composed of two parallel lines drawn perpendicular from the chief to the base of the escutcheon, and should contain one third part of the breadth of the shield. See Fig. 2.

*N. B.* The *pale* admits of two subdivisions, or diminutions, as to its breadth. The half of the *pale* is called a *pallet*; and the half of the *pallet* is called an *endorse* or *verget*. According to the strict rules of heraldry, neither *endorse* nor *pallet* can be charged.

3. The Bend, which is formed by two equidistant lines drawn diagonally from the dexter chief to the sinister base of the escutcheon, according to a rule laid down by Leigh, Holme, Guillim, &c. should, if charged, be in breadth one-third; if not charged, one-fifth of the shield. Others make no such distinction, but tell us, that the *bend* possesseth always the third part of the escutcheon from the right chief angle to the left base angle.

When there are more than *one bend* in a coat, they are called *bendlets*; but when the field is equally divided by 4, 5, 6, 8, or 10 lines, or any even number *bendways*, then it is termed *bendy* of so many pieces.

The *bend*, or as it may be called for distinction sake, the *bend dexter*, has more subdivisions or diminutives than any of the other ordinaries: 1*st*, The *bendlet*, which should contain one-sixth of the shield; 2*dly*, A *garter*; 3*dly*, A *cottise*; 4*thly*, A *ribbon*, none of which can be with propriety charged. See Fig. 3.

4. The *bend sinister*, which passes diagonally from the sinister chief point to the dexter point in base, has not the same diminutives as those of the *bend dexter*; but, according to some heraldic writers, is subdivided into a *scarp* or *scarf*, which has just half the breadth of the *bend sinister*, and a *batton* or *fissure* containing half the breadth of the scarf. See Fig. 4.

Many, however, will by no means admit of the *batton* being said to be a diminutive of the *bend sinister*, or any part of any of the ordinaries. According to many years practice, the *batton* does not touch the extremities of the shield, nor the extremities of the quarter where the paternal arms are placed, as all the ordinaries do, but is, on the contrary, *couped* or cut short, and so borne as a mark of illegitimacy, (as may be seen in the arms of the Dukes of St Albans, Grafton, and Buccleuch, all descended from bastards of King Charles the Second,) and not as an ordinary or charge, or any part of the coat. For although some instances are to be met with of ancient arms, where the *batton sinister* is passed from the sinister chief to the dexter base over all, and others where it passes from corner to corner over the paternal arms, and not over the other quarterings; yet in every one of these it is used as a mark of illegitimacy, and not as either an ordinary or a charge. This mark or batton may, in the arms of royal bastards, be of metal or fur, or both; but in the escutcheons of those of the humbler sort, of colours only. When both a *bend dexter* and a *bend sinister* occur in the same coat, that is first mentioned which lies nearest the shield; thus *argent*, a bend azure surmounted by a bend sinister.

5. The Fess is formed by two lines drawn horizontally across the shield, and is understood to comprehend in breadth the third part of the shield, though less room is often assigned to it. This ordinary cannot be divided or diminished like the *bend*, but may be *voided*, a form to which all the ordinaries are liable. *Voided* is said of an ordinary when its middle is cut away, so that no more of it remains visible than the two outside lines; as *azure* a *fess voided argent*, by the name of *Bleckall*.

6. The Bar is formed by two equidistant lines drawn horizontally across the middle or centre of the escutcheon, after the manner of the *fess*, but containing one-fifth part only of the field. The *bar* hath two diminutives, viz. a *closet*, which is in breadth one-half, and a *barrulet*, which is in breadth one-fourth of the *bar*. When the field is dividep into 4, 6, 8, 10, or 12 equal parts, it is then blazoned *barry*; and when the diminutives of the bar are placed in pairs on the shield, they are called *bars gemelles*, from the Latin *gemelli*, twins.

7.· The Escutcheon itself is deemed an ordinary, and is composed of three lines. It may be carried singly, or with others, as in the coat of Hay, argent, three escutcheons, gules. See Fig. 7.

N. B. Inescutcheon signifies the same thing.

8. The Border hath, by several writers, been refused admittance into the number of ordinaries; they alleging, that it is not a principal figure, but a difference only. Nisbet, however, very properly observes, that this is quite unjust, inasmuch as many coats consist of other charges than the *border* alone. In blazon, borders always give way to the chief, the quarter, and the canton; so that, in coats charged with one of these ordinaries, the border goes round the field until it touches it, and there finishes; but, in respect to all other ordinaries, it passes over them. When a border is of two colours, and divided into squares, it is called a *border compony* or *compony*; if it hath two rows of squares, it is called *counter compony*; if three, it is called *cheque*.

A border *purflewed* is shaped exactly like *vair*: when it is of one row, it is called *purflewed*; when it is of two rows, it is *counter purflewed*; when of three, *vair*. The border *enalcron* is a border charged with birds; the border *entoiré* is charged with *besants*; the border *verdoye* is charged with vegetables; the border *enurney* with lions, &c. But these terms ought all to be discarded as useless.

9. The Orle is an inner border of the same shape as the escutcheon, and doth not touch the exterior of the shield, the shield being seen within and around it on all sides, so that it appears like an escutcheon *voided*. The edges of the *orle* may be ingrailed, indented, invecked, &c. When any bearings, as martlets, mascles, &c. are placed round an escutcheon on a field, they are said to be *in orle*; and it is needless to mention the number of them, for figures so placed are always supposed to be eight in number. See Fig. 9.

The Tressure is a diminutive of the orle, formed by a small line or trace passing along the field, and encompassing the inner part of the escutcheon in the same form as that of the shield. In some coats, the tressure is formed of two lines or traces, *flory counter-flory*, as in the arms of Scotland. Indeed, unless it be of this sort, it may as well be called an orle as a tressure, as Edmonstone has well observed.

10. "The Flasque consists of an arched line drawn somewhat distant from the corner of the chief, and swelling by degrees till you come towards the centre of the escutcheon, and then decreasing again with a like descent unto the sinister point base." See Fig. 10.

"The Flanch is formed of an arched line, taking its beginning from the corner of the chief, and from thence compassing orderly with a swelling embossment, until it come near the nombril of the escutcheon, and thence proportionably declining to the sinister base point." So says Guillim; but Gibbon and Edmonstone are both of opinion, that these two ordinaries are one and the same. The *voider* is certainly a mere diminution of the flanch, and, by reason of its smallness, cannot be charged.

11. The Saltier, or *Sautoir*, is an ordinary, consisting of a fourfold line, two whereof are drawn from the dexter chief towards the sinister base corner; and the other two from the sinister chief to the dexter base point. If not charged, it containeth one-fifth of the field; if charged, one-third. See Fig. 11.

12. The Cross, after the expeditions to the Holy Land, came to be an ordinary of most frequent use. It is composed of a fourfold line, whereof two are perpendicular and two horizontal; so that it seems to be formed of the *pale* and the *fess*, not lying on one another, but corporally united in the centre. The great variety of crosses used in heraldry is such, that in all considerable systems several pages are filled with engravings of them, Fig. 12. The most considerable are, the cross *patée*, Fig. 13; the cross *potence*, Fig. 14; the cross *avellane*, Fig. 15; the cross *furche*, Fig. 16; the cross *crosslet*, Fig. 17; the cross *botone*, Fig. 18; the cross *flory*, Fig. 19; the cross *patée fitched*, Fig. 20; the cross *pierced*, Fig. 21; the cross *moline*, Fig. 22. The proportions of the cross are exactly the same as those of the saltier.

13. The Cheveron is an ordinary, formed of twofold lines placed pyramidically, and is resembled to a pair of barge-couples or rafters, such as carpenters use to support the roof of a house. Its diminutives are the *chevronel*, which is half the chevron; and the *couple close*, which is half the chevronel. See Fig. 23.

14. The Fret is formed of six pieces, two of which compose a saltier, and the other four a mascle, over which the saltier pieces must be interlaced. When the fret is composed of 8 or 10 pieces, we say, *or fretty azure*, &c. See Fig. 24.

15. The Pile is an ordinary, composed of a twofold line, which forms a long wedge, broad at the top, and terminating at the base in an acute angle. See Fig. 25.

16. The Giron is an ordinary of a triangular or conical form, composed of two lines drawn from diverse parts of the escutcheon, and meeting in an acute angle in the *fess point*. This may be borne singly, or in couples, to the number of 4, 6, 8, 10, or 12. When there is only one gyron in a coat, it is blazoned thus, *argent a gyron sable*, without mentioning the point from which it issues, that always being supposed to be the dexter chief point; but if it stand elsewhere, it must be expressed. If there be six gyrons

in a coat, it is blazoned, *gyrony of six, or and sable*, and so of any greater number. See Fig. 26.

17. The Quarter is an ordinary, composed of two straight lines, containing one-fourth part of the shield. See Fig. 27.

18. The Canton is of a square figure less than the quarter, containing one-third of the chief. See Fig. 28.

19. The File or Label, though used as a distinction of houses, is very properly placed among the ordinaries by Holme, by reason that it is variously borne and charged.

*Of Charges or Figures not peculiar to Heraldry.*

26. Anciently arms were simple and plain, consisting of at most a few figures distinctly set forth on the shield; the heralds of those days being universally of opinion, that the plainer a coat is the more honourable it should be esteemed. The arms of the house of France, were simply three fleur-de-lys *or* in an azure field. The royal arms of England, at most three lions *or* on a field *gules*. The arms of Waldgrave, simply *per pale argent and gules*. Those of Burgundy *ermine* alone, without any charge whatever. As coats of arms increased in number, a deviation from this original simplicity soon became unavoidable; a conspicuous variation from each other was absolutely requisite; and this necessity was never more felt than in camps and tournaments. This at first was effected either by a repetition on the same escutcheon, of some one or other of those particular figures, which had heretofore been used as charges; or by placing in the field two or more distinct bearings. It was not long, however, before this mode proved inadequate to the purpose for which it was intended. The continual multiplication of arms had exhausted all the variations of which armories were, as they then stood, susceptible, and called for additional marks of distinction. Wherefore such a multitude of new charges have been from time to time introduced, that it may be truly said, there is scarce any thing either natural or artificial that is not, or has not been, represented in a coat armour.

The embarrassments which, from the multiplicity of coats of arms, and the infinity of charges former heralds lay under, in the contriving new armories, so as not to have them clash with others already in use, led them, as might well have been expected, into many absurdities; but to their praise it must be said, that they not only avoided, with great caution, all improper or indistinct figures, but blazoned what they did select with so much fulness and nicety, that none could be at a loss to draw them with accuracy and exactness. Modern heralds, however, have not always followed their good example in this respect; on the contrary, they have stuffed the newly purchased coats with such a multitude and variety of charges, and introduced such a medley of novel and extraordinary bearings, that these escutcheons are for the most part crowded, confused, and unseemly, and of consequence altogether inadequate to the original purposes of coat armour.

Possibly they are desirous of giving good pennyworths, and think that as purchasers now pay much dearer for their arms than they used to do, they are entitled to a greater number of bearings on that account. The arms granted to one Edward Chambers, of the island of Jamaica, afford a notable instance: "*Argent a negro cutting with a bill a sugar cane, all proper: on a chief azure two pine-apples* or, *leaved of the last*. But the escutcheon of an officer lately returned from the East Indies, viz. lieutenant John Nathan Hitchins, presented still greater absurdities: "*Quarterly 1st and 4th vert an elephant and tiger rampant combatant, an officer of the honourable East India Company's dragoons standing by with a musket in his dexter hand, and a dead horse couchant in the sinister point base, all proper. 2d and 3d gules between three pieces of ordnance* or *on a chevron argent two oriental tiaras contre embattled proper.*" The motto, "*Auroram et Gangem pauci dignoscere possunt.*" Another grant runs thus: "*Sable on a chevron between 2 pistols in chief* or, *a silver medal with the French king's bust, inscribed 'Louis XV. par la grace du Dieu Roi de France et Navarre,' tied at the top with a ribbon gules. A laurel chaplet in the centre, a scalp on a staff on the dexter, and a tomahawk on the sinister, all proper*. For the crest: *On a wreath a rock; over the top a battery in perspective; thereon the French flag hoisted, an officer of the Queen's Royal American Rangers climbing the said rock sword in hand, all proper!*"

The arms of one Templar are thus blazoned in the grant: "*Quarterly azure and gules, the perspective of an antique temple; on the pinnacle and exterior battlements a cross moline* or. *In the first quarter, an eagle displayed. In the second, a flag trippant, regardant of the last.*" The arms of Mr William Stitlington, teacher of philosophy in Wapping, are thus: "*Azure on the ecliptic circle* or, *the sign* Libra; *in chief, a terrestrial globe on a stand, all proper; and in the base, on a mount vert,* a male child *extended in bend sinister proper*. Crest, *On a wreath, a holy lamb regardant ermine accolled with a laurel branch vert, holding a banner proper*. Motto, *Have mercy on us, good Lord.*" On the ridiculous parts of these armories, and the incomprehensible jargon in which they are set forth in the grants, it would be absurd to enlarge. The arms are such as no ancient herald, rightly embued with the principles of his art, could understand; and no painter can properly represent without the help of inspiration, unless he can see the painting on the margin of the grant.*

Many other examples of a like sort might be produced; but, to those already mentioned, we shall only add that of the bearing granted to one Mr Tetlow, which is so extraordinary, in respect to the coat as well as the crest, that it is not, by any means, to be omitted in this place. In the arms are *five music bars*; and the crest is thus set forth: "*On a book erect gules clasped and leaved* or, *a silver penny argent whereon is written the Lord's prayer; on the top of the book a dove proper, in its beak a crow-quill pen sable;* in commemoration, as is said, of the brother of the grantee having written the Lord's prayer within such a compass.

Neither can any one greatly approve of a grant of arms, wherein we find "*a troubled ocean with Neptune rising therefrom, holding in his sinister hand part of the wreck of the ship Royal George*," to indicate, that the uncle of the grantee had suffered shipwreck along with Kempenfelt; or of a grant, wherein is introduced "*a China porter carrying on a yoke two faggots of cinnamon*," to indicate that the grantee had once made a voyage to the Dutch islands; and yet all these absurdities arise from the present or late system of *charges* adopted in the herald offices.

But to return from this digression, if such it deserves to be called, to notice particularly all those figures which are, even by the most excellent authors, admitted as proper for the practice of heraldry, would be altogether inconsistent with the limits of an article such as this. The principal only can be noticed; and, in the first place, it is fit to observe, that of charges some are round in shape, some square. The former are generally called *roundles* or *roundlets*; and of these, which differ from each other in name

* In the same taste, a la[illegible] tutor and examining master at Oxford assumed as crest, "*on a cap of maintenance a mark of interrogation nebulé.*" Motto "το της πολλης πειρας τελευταιον επιγεννημα." The congenial escutcheon—"*gules, a fair exemplar of* The Ethicks *expanded proper!*"

according as they are of different tinctures, there are nine; seven of them being perfectly globular, and two of them flat like a piece of coin.

*The Roundles, or Roundlets.*

| When they are | | | |
|---|---|---|---|
| 1. Or, | | are then called | 1. Bezants. |
| 2. Argent, | | | 2. Plates. |
| 3. Vert, | | | 3. Pomeis. |
| 4. Azure, | | | 4. Hurts. |
| 5. Sable, | | | 5. Ogresses, or Pellets. |
| 6. Gules, | | | 6. Torteauxes. |
| 7. Purpure, | | | 7. Golpes. |
| 8. Tenne, | | | 8. Oranges. |
| 9. Sanguine, | | | 9. Guzes. |

1. Bezants, when they are armorial figures, are flat pieces of plain gold, without any stamp or impression upon them. When introduced into heraldry, they had their name from the ancient coin of Constantinople, or Byzantium.

2. Plates are likewise flat, as representing thin pieces of silver bullion when fitted for the stamp.

The other seven figures are always globular, viz.

3. Pomeis, which derive their name from the French *pomme*, an apple.

4. Hurts, so called from their resemblance to a small blue fruit, named hurtle berries.

5. Ogresses, or Pellets, resemble bullets for guns. In blazon, they are generally termed pellets, but some of the ancient heralds call them *gun-stones.*

6. Torteauxes take their name from the French appellation of a certain species of round cakes, which, in England, used to be called wastal-cakes, or wastals, by which name we often find them distinguished in ancient blazons.

7. Golpes, according to Gerard Leigh, are wounds; and Guillim even thinks they may be called so in blazoning.

8. Oranges, the well-known fruit.

9. Guzes are said to represent eye-balls; but these are of very rare occurrence even in English heraldry.

When any of these nine figures are in a coat, and countercharged, they lose their beforementioned respective names, and are all indifferently stiled roundles; so that if we look at the painting of a coat-armour, which is blazoned *per pale* or *and gules three roundles*, we shall find, that, of the two figures in chief, one is a *bezant*, and the other a *torteaux;* and that the solitary figure in base being divided *per pale gules and or*, the one half thereof is a *bezant*, and the other half a *torteaux*. When the field is strewed with any of the first five beforementioned figures, or if they are placed on crests, supporters, or any ordinary or charge, they are termed, *bezanté*, *platé*, *pometté*, *hurté*, and *pelletté;* but if the field be strewed, or semée, with any of the four last mentioned roundles, we say, *semé of torteauxes*, *semé of golpes*, *semé of oranges*, and *semé of guzes*.

Foreigners have no more than two specific names for all these round figures. When they are of metal, they call them *bezants;* when of colour, *torteaux;* therefore they say, so many *bezants d'or*, or *d'argent;* or so many *torteauxes d'azure*, *de gules*, *de sable*, &c. and when they are half metal, half colour, if the metal hath precedence in position, they say *bezant-torteaux* of such metal and colour; and so, *e contra*, *torteaux-bezants*, when the colour precedes the metal.

The roundlet voided, is the *annulet*, or ring. When these pass into one another, the French say *vires.*

*Of Guttes.*

Another sort of charge very common in armories receives, in like manner as the roundlets, divers names of blazon, according to the variations of its tinctures. This charge is called *guttes*, i. e. *drops* of things liquid, whether by nature or by art.

| If they are | they are termed | i. e. |
|---|---|---|
| or | guttes d'or | drops of gold |
| argent | guttes d'eau | water |
| vert | guttes d'olive | oil of olives |
| azure | guttes de larmes | tears |
| sable | guttes de poix | pitch |
| gules | guttes de sang | blood |

Guillem, indeed, says these are seldom borne alone; but Edmonstone differs from him, and instances, among other examples of *guttes* borne as a charge,

*Argent three guttes de poix*, for Crosbie.

But it is true they are much oftener borne strewed on fields, ordinaries, charges, crests, supporters, &c. and in such cases, whatever is charged with them is blazoned thus, *Argent gutty de sang*, which denotes that the whole escutcheon is sprinkled with red drops, and so in regard to a crest, *a lion's head gules gutty d'argent.*

There are three square figures deemed to be proper charges, the lozenge, the fusil, and the mascle. Of these the two former have been already mentioned and described as applied to a different purpose. The field or ordinary may be covered with *lozenges* or *fusils*, and it is then called *lozengy*, *fusilly*. If fusils are borne in pale, as *a pale fusilly*, or *six fusils in pale*, they must lie fesswise, *i. e.* their acute angles must be dexter and sinister. But if a *fess fusilly*, their acute angles must be in chief and base.

The *mascle* differs from both lozenge and fusil in this respect, that, according to the sentiments of all authors, it must be pierced through, or *voided.* When any coat in which one or more mascles occur is blazoned, their number is mentioned; and if they be close together, or conjoined, that circumstance is not omitted, thus, *Argent a mascle in fess between three pellets sable.* Osbaldeston, *sable five mascles conjoined in cross or.* Brandreth, *gules seven mascles conjoined or three, three, and one.* The coat of De Quincy, Earl of Winchester, well known by ancient seals. Plate CCXCI. Fig. 2.

The *Billet* is an oblong figure, supposed to take its name from its resemblance to a *billet of wood.*

*Rules for Blazoning.*

When a coat of arms is blazoned, the field is first mentioned, next the ordinary, last of all the charge. If the coat consists of two colours only, as the coat of Hatton, we may say, *azure a chevron between three garbs or*, which implies that both chevron and garbs are *or.* Or thus, *azure a chevron or between three garbs of the last.*

When the charges next to the field are mentioned, then proceed to those which lie more remote, as in the coat of Pratt, sable on a fess between three elephants' heads erased argent as many mullets of the first. Here the mullets, being the most remote from the field, are last mentioned, and as both field and mullets are sable, the words *of the first* are used to avoid repetition.

When a field is divided by lines, they must always be mentioned before the colours, as in the coat of Waldegrave, before mentioned, *parté per pale argent and gules.* Aston, *parte per chevron sable and argent.* Boyle, *parte per bend crenellé argent and gules.*

N. B. Besides the above mentioned charges, there are other two, rejected indeed by our English heralds, but of common enough use among foreigners.

1. A shield is by them called *papilloné*, when it is covered with figures like the scales of fish.

2. "Diaspré, or diaperé, is said, when the field is shadowed with flourishings and various turnings, by *purfels* of gold or silver, or tinctures after the fashion of flowers or leaves, like the weaver's diaper-napery." The Germans practise this most, as the French do the *papilloné*.

Concerning all the figures we have as yet observed, whether under the head of ordinaries, or under the present, heraldic writers are much at variance among themselves. Some arrange them all under the head of ordinaries, dividing them in honourable ordinaries, and subordinaries. Others, and among the rest Edmonstone, adopt that order which we have observed. Indeed, uniformity in this matter could by no means be expected among authors who differ from each other upon matters of so much greater importance in their art. Those figures which are by one set of writers affirmed to be altogether peculiar to heraldry, are by others considered as evident representations of objects the most familiar in nature or in art. As to those figures which we shall next take into consideration, they are all of one mind. Heraldry has, according to every authority, borrowed them from nature.

*Of the Celestial Figures used in Armories.*

27. 1st, The *Sun*. When of the metal *or*, it is said to be proper; when of one of the colours of heraldry, it is called *ombre de soleil de gules*, &c.

2d, The *Moon*. When full, said to be *in* her complement. The half moon is styled *crescent*, *increscent*, *decrescent*, and *crescent reversed*, according to her position in the shield; *crescent*, when the horns are towards the top of the escutcheon; *increscent*, when the horns are towards the right side of the shield; *decrescent*, when the horns are turned to the left; and *crescent reversed*, when they are pointed towards the base. The crescent is the cognisance of the Ottoman emperors. Aben Mahomet, the great Moorish prince, who overran Spain, carried the *crescent reversed*. All over Spain, the crescent is a common bearing, in consequence of the achievements of particular families against the Moors.

3d, *Stars*. They are represented generally with five points. *Mollet* in French and Scottish heraldry means a figure of the same sort, of six points, and *pierced*, supposed to be the *revel* of a spur. But the English call stars of five points, mullets, unpierced, or *estoils* simply. When *pierced* they blazon them so—as, The name of Doughty in England. *Argent two bars between three mullets of six points pierced sable*.

Comets, spheres, and rainbows, are also used in heraldry, as, *argent a rainbow*, by the family of Leiris in Languedoc, in allusion to their name, *L'iris*.

*Of Man and his Parts in Arms.*

28. The use of these charges may be supposed to have arisen in a great measure from the practice of kings and great men, particularly churchmen, having on their seals representations of themselves, their patrons, saints, &c. Thus the arms of the see of St Andrews in Scotland were *azure, St Andrew carrying on his breast his proper cross (or saltier) argent*.

When any part of the human body is represented as cleanly cut off as by a sword, it is said to be *couped*; if *torn off*, *erased*; in French, *arraché*, in Latin, *avulsum*.

Heads are frequently represented as surrounded with a wreath or bandage, and they are then said to be *banded* or *tortille*. Moors' heads (always in profile) are common in Spanish coats as trophies.

*Of Animals.—Lions, &c.*

29. Lions standing upright, with only one eye seen, are called *rampant*; if full faced, *rampant guardant*; and if they are looking behind them, then the word *regardant* is added to that which speaks the attitude, as *passant regardant*, *rampant regardant*. Lions, when represented as feeding, are called *rapin*; and when in an attitude of springing with both their hind legs together, they are termed *saliant*; as are also bears, wolves, unicorns, and all other beasts, except *griffins*, which are termed *segreant* instead of *rampant*. The tongues and claws of all beasts are in general represented in coat-armour, as of a tincture different from that of their bodies, and are termed *langued* and *armed*, as, *argent, a lion rampant rampant regardant gules langued and armed azure*. Farther, it is a general rule, that when any beast is tinctured *azure*, the tongue and claws are *gules*; and *vice versa*, except when it is otherwise expressed.

When any animal proceeds from the bottom of a chief, fess, &c. it is termed *issuant*; and when it proceeds from the fess or ordinary, it is termed *naissant*. A *demi-lion* is half a lion, so proceeding, *couchant passant*, and the rest are sufficiently intelligible.

When any beast in a field has a fess, bend, &c. passing over him, he is said to be oppressed, depressed, or *debruised* with a fess, &c. When a beast is on a field, which is *per chevron*, it is said to be counterchanged. Wherefore the chevron line must continue its course through the beast, and the beast be painted of two colours of the field; for example, *Per chevron argent et sable a lion rampant counterchanged*. The upper part of the lion, so far as to the chevron line, is sable, the lower part, from the chevron line to the base, argent. Again, if the field is *paly, of four or and azure*, and over all a lion rampant counterchanged, some part of the lion must of consequence lie on each of the four pales, and therefore the lion must be painted of the different colour of each pale.

Lions, &c. may be borne of several pieces; as for example, *gules a lion barry wavy of eight argent and or*, by the name of Harrowden. *Gules a lion rampant cheque or and azure*, by the name of Cobham. *Gules a lion rampant barry of ten argent and azure*, by the name of Desney. *Gules a lion rampant vair crowned or*, the old bearing of Marmion. They may also be carried *dismembered* of head, feet, and tail. When a lion is said to be *dismembered*, the parts are put a little distant from each other, yet so as to preserve the form and shape of the lion. If dismembered of any particular part, it should be mentioned; as dismembered of the head, if the head be cut off, &c.

If tongue or claws be cut off, he is said to be *disarmed*. If the parts cut off be not in the field, he is blazoned thus, *argent a lion sans tail gules*, &c.

Some call a lion rampant without tongue or claws a lion *mortue*; and the lion *sans tail* they call *defamed*. A lion rampant holding in his mouth a staff or batton, is said to be *bailloné*. One rampant, or sejant, (*i. e.* sitting) with his face to the sinister, is termed *Contourné*. If the eyes of lions are of a fiery colour, they are called allumés, or incensed; if their tails hang between their hind legs, they are termed *coward*.

When a whole fore-leg of a lion or other animal is borne in an armory, it is called *a jambe*; but if couped or erased near the middle joint, it is termed *a paw*.

As lions may be dismembered, so they may have additions made to them; as a lion with two or three heads, or one head with two or three bodies. Another bearing not uncommon is that of lions with two tails, which are moreover represented under various circumstances, as with *two tails erect*, *two tails forked and wreathed*, i. e. two tails twisted over one another, and having the two ends forked; and with two tails *nowed* or *notted*.

But as beasts of all sorts are blazoned in the same terms as the lion, we have given, in Plate CCXCII. representations of this animal in the principal attitudes in which heralds place him.

Fig. 30. Stattant. 31. Passant. 32. Passant-gardant. 33. Passant-regardant. 34. Rampant. 35. Rampant-gardant. 36. Rampant-regardant. 37. Salient. 38. Sejant. 39. Coward. 40. Couchant. 41. Dormant. 42. Naissant. 43. Issuant. 44. Combattant. 45. Lions endorsed. 46. Lion demi-rampant erased. Lion's head coupé. 47. Lions jambe erased. 48. Lions tails erased.

### *Of the Tiger and Antelope.*

The manner in which these two animals were anciently expressed in armories, is so dissimilar from the real figures of those well known animals, that it is not without difficulty we can recognise them. The heraldic tiger is drawn much in the shape of a wolf, with the tail of a lion, and thereon, as also on the inside of his hind legs, and on his chest, tufts of hair. On the back of his neck is a mane composed of separate tufts, similar to those *tusks* which are used in ornaments, and at the point of his nose is a tusk like that of a boar bending downwards. The imaginary antelope of former days is the same figure as this tiger in every respect, save that on his head he has two horns, whose edges are indented like a saw, and that he is hoofed like a buck.

Besides those two creatures of heraldic fancy, the blazoners of old times invented a third, which they made of the same form, and tufted and maned exactly like their tiger and antelope, but with this variation, that he has two straight horns projecting from the head. This they term an *ibex*.

### *Of Birds*, &c.

30. Birds painted of their natural colours are termed *proper*, and their claws, or talons and beaks, are called *arms;* thus *argent a falcon proper armed* OR, implies that he is taloned and beaked of gold. To distinguish the falcon from the eagle, the former bird is generally depicted with bells on his legs, and this is termed *belled;* but if the thongs of the leather by which these bells are attached, are flying off from the legs, then the falcon is said to be *jessed and belled.* Falcons, eagles, or hawks, drawn feeding, are termed *preying.* When the wings, &c. are both behind the head, and back to back, they are termed *expanded*, *expansed*, or *adossed;* and when the wings are on either side of the head, and the points are erect, they are termed *elevated.* An eagle with wings elevated and legs extended, is termed a *displayed* or *spread eagle.* If the eagle has two heads, the blazon runs thus, *sable an eagle with two heads displayed* OR.

The eagle without legs, wings, tail, &c. is blazoned thus, *gules an eagle with two heads erased in the middle of the body*, *sans wings argent*, by the surname of Barlow. Parts only of eagles, &c. may be carried in coat-armour: wings by pairs are called *wings conjoined;* and if their points be downwards, *inverted* or *in lure*, as in the arms of Seymour. *Gules two wings conjoined in lure* OR. All birds, *not of prey*, having their beaks and legs of a different colour from their body, are called *membered*; as to claws and talons, *armed.*

When SMALL BIRDS are borne in armories, they are all represented after the same shape, of whatever tincture they be, and in our blazon are termed *birds* alone, in French "*alerons.*" *Martlets*, though principally used as a mark of distinction of houses, are nevertheless a bearing by no means uncommon. The English draw them as birds without legs. The French amputate them still more, and give them neither *beak*, legs, nor thighs.

COCKS are said *to be armed*, *crested*, and *jelloped; armed* signifies the beak and spurs, *crested* the comb, and *jelloped* the wattles or gills.

A SWAN, when he has a ducal coronet on his head, and a chain thrown over his back, is termed *a cygnet royal.* When a swan's head is borne, it is always blazoned *a swan's neck* couped, erased, &c.

Birds on wing are said to be *volant.*

FISH, when placed horizontally, are termed *naiant;* when placed perpendicularly, with the head in chief and tail in base, *haurient*, *i. e.* drawing in air; when bent, they are said to be *embowed*, (the dolphin is commonly represented thus.) When two fish are placed face to face, they are said to be *respecting each other;* if back to back, *endorsed.* Flowers of three leaves are called *trefoils*, of four *quatrefoils*, &c. When the human figure is borne clothed, it is termed *vested* or *habited.* Thus for a crest, *on a wreath*, *a dexter arm embowed*, *vested gules*, *cuffed argent*, *holding in the hand proper a rose of the last.* This implies the sleeve of the coat to be red turned up with white. Robes, vestments, and habits of all sorts, crowns, sceptres, crosiers, cardinals' hats, gloves, stockings, shoes, brogues, armour for man and horse, all military machines and engines, arms offensive and defensive, rings, jewels, and other ornaments, coins, dice and chess-rooks, all articles of husbandry, all tools of trade, and in short almost every thing celestial or terrestrial, from the sun in the firmament to a carpenter's nail, have been represented in heraldry; and nothing more frequently than those creatures which have no existence except in the imagination of the poets and romancers: centaurs, unicorns, mermaids, wyverns, (*i. e.* adder-tailed dragons,) montegres, (*i. e.* monsters with the bodies of tygers and the heads of satyrs,) are abundantly to be met with. Nay, in the arms of the elder time, and more particularly in those of churchmen, we daily encounter such combinations of cherubim, seraphim, and angels, (*affrontés volants, and with wings displayed*,) as, to say the least of them, appear not a little indecorous. Astonishing, they certainly cannot be esteemed, if we take into our consideration, that they are the works of the same men, who thought that the art of heraldry itself was one of the important secrets transmitted at once *viva voce* to Adam from his Maker, as being of too great depth and dignity ever to have been discovered by the mere unassisted intellect of man.

### *Of Marks of Cadency.*

31. The several figures or marks of cadency, which have of later times been used for the differencing and distinction of houses, in order that their degrees of descent may be known, are for the first an ALABEL; for the second a CRESCENT; for the third a MULLET; for the fourth a MARTLET;* the fifth an ANNULET; the sixth a FLEUR-DE-LIS;

* This bird represented in heraldry as *απους* or *sive pedibus*, "is given," saith Bekenhawth, "for a difference to younger brethren, to put them in mind to trust to their wings of virtue and merit to raise themselves, and not to their legs, *having little land to put their foot on.*"

the seventh a rose; the eighth a CROSS MOLINE; and for the ninth a DOUBLE QUATREFOIL. See Plate CCXCII. Figs. 50—55.

These marks are said to have been invented by modern heralds, in order that coat-armour might descend to posterity with safety. Certain it is, however, that they are far from answering some at least of the purposes for which they were intended; for these marks, when painted on a shield of arms, are so small, complicated, and confused, that they are scarcely distinguishable. The ancient heralds adopted a better method. They made choice of more conspicuous brizures, and pitched on the border the bend, and armorial additions, as also changes of the tinctures, and of the position of the charges, as being more intelligible tokens of difference. Thus an old family of Salop, the Corbettes, bore *or a raven sable*, the second branch took *two ravens*, the third *three*, the fourth *four*, and a still younger branch bore their *ravens within a border*. It was the most usual method to have these borders of difference composed of the arms of the first marriage, that had established the particular branch of the family which first assumed such border. The Manwarings of Salop bore *argent two bars gules*. The younger branches went on increasing the number of bars, till one took *ten bars*. The Warrens originally bore *cheque or and azure*. But the younger branch took *cheque or and azure on a canton gules a Lion rampant argent*, being the arms of the mother, a Mowbray. Others took a part of the maternal coat, and added to their father's coat, to shew that it was a younger branch descended on the mother's side from such a particular family. At present the above mentioned marks of distinction, *label*, *mullet*, &c. are so combined with each other as to difference almost *ad infinitum*. The daughter of a house bears her father's mark of cadency, but not any to shew that she is first, second, or third daughter.

*Of Additions of Honour.*

32. Certain ordinaries have been, from what cause it is difficult to say, selected as more proper than others for bearing and exhibiting heraldic additions of honour, and augmentations of arms. These are nine in number, viz. the *border*, the *quarter*, the *canton*, the *gyron*, the *pile*, the *flasque*, the *flanche*, the *voider*, and the *escutcheon of pretence*. These have all at various times been in vogue. In the days of King Henry VIII. the *pile* had the preference, and was by him granted to the Lady Jane Seymour, and to the Lady Catharine Parr. But of late years, the *quarter* and *canton* are most in use.

*Abatements of Honour.*

33. By *abatements of honour*, we are to understand "Such figures as heraldic authors affirm were, by judgments of the court military, to be added or annexed to coat-armour, in order to denote some ungentlemanlike, dishonourable, or disloyal act, demeanour, quality stain, or vice in the bearer, and whereby the dignity of the said coat-armour is greatly abased." These abatements of honour are in like manner nine in number, viz.

1st, *A delf* (or turf) *tenné*, for him who revokes or recedes from a challenge.

2d, *An escutcheon reversed sanguine occupying the middle point of the escutcheon of arms*, for him who deflowers a maid or widow, or flies from the banner of his prince.

3d, *A point dexter parted tenné*, for a braggadochio, or vain-glorious boaster of acts unperformed.

4th, *A point in point sanguine*, for a person guilty of cowardice.

5th, *A point champaine tenné*, for him who kills his prisoner after quarter demanded.

6th, *A plain point sanguine*, for him who lieth to his prince or general.

7th, *A gore sinister tenné*, for him who behaveth basely towards his enemy.

8th, *A gusset sanguine*, on the dexter side of an adulterer, on the sinister for a drunkard.

9th, *The whole coat turned upside down, or reversed*, for a traitor.

N. B. These figures are always given in the English systems, but are ridiculed by the Stotch writers, and by the Jesuit Menestrier termed "English fancies." The truth is, no instance is furnished in any of the books of such figures being actually borne for the purposes alleged. Certain it is, that many of these figures are frequently used as marks of honour.

*Of Marshalling Coat-Armour.*

34. "Arms," according to Nisbet, "are said to be marshalled, when ensigns of honour and dominion, or the entire arms of other families, are joined with the paternal arms of the bearer by partition lines, making distinct areas or compartments in one shield." Edmonstone defines marshalling of arms "an orderly disposing of sundry coats belonging to dictinct families in their proper places within one shield, by impaling and quartering." Marshalling is moreover extended to the disposition of the appurtenances of such arms without the escutcheon.

Women, unless they are sovereign queens or princesses, by the rules of heraldry, bear their paternal arms in a lozenge or shield; and therefore, when they marry, it has been the custom to impale their arms with those of their husbands, in order to shew that alliance; which is called "*arms en baron et femme*."

Impaling has been practised in three different manners. First, by *dimidiation*, (Plate CCXCIII. Fig. 1.) that is, by halving or cutting the shields of both husband and wife into two equal parts, and joining the dexter half of the husband's to the sinister half of the wife's, so as to form one shield. In this mode (called in their tongue *accolée*) the French kings used to impale the arms of Navarre. The second mode is dimidiating the husband's arms, and impaling them with the full coat of his wife, (Fig. 2) The third mode (Fig. 3.) and that now in use in England, is that of impaling the two full coats, except when one of them hath a border; for this can never be carried all round an impaled shield, but must stop at both ends where the two shields meet, (Fig 4.)

Dimidiation of arms was much used long before entire impalements were in use. Margaret, sister to Philip IV. of France, and second wife to Edward I. of England, had on her seal, in the year 1299, the arms of England so dimidiated with those of France, and she was the first queen of England who had her arms so marshalled. The same method prevailed in France up to the time of the Revolution. But the reasons which have induced the English heralds to lay it aside are certainly very powerful; for were it practised as of old, no end could be put to the jumble and confusion which it must infallibly create. For example, dimidiate the arms of CLARE, viz. *or three cheverons gules*, and impale them on the woman's side with any coat, and you will have *or three bends gules*. Again dimidiate the coat of Waldegrave, viz. *per pale argent and gules* for the man, and it will be only *a white field*; but do the same for the sister, and then it becomes *a red field*.

Besides this impaling by way of *baron and femme*, the husband in Scotland frequently quarters his wife's coat with his own, on account of her being an heiress, *i. e.* he divides a shield into four equal parts by coupe and party. In the first and fourth *areas* are the husband's arms; in the second and third those of the lady: (See Fig. 5.) But in England the husband of an heiress more commonly places his wife's arms on an inescutcheon in the centre of his coat, and this is termed *an escutcheon of pretence*. See Fig. 6.

The other methods of accumulating many coats in one shield, which have been of common use in other European countries, have never much prevailed in Scotland. Of these the principal are, FIRST, *that by tranchie and taille-lines;* thus a coat parted per saltier, is divided into four conal quarters or areas, &c. called in French *tranchée taillée*, as in the well-known arms of Sicily. *Quarterly per saltier, first and fourth, or four pallets gules* for Arragon; *second and third argent an eagle displayed sable, beaked and membered gules*, for Suabia. (Fig. 7.) SECONDLY, (as in Fig. 8) by surmounting coats already quartered with inescutcheons, by the French termed *surletout*. When this inescutcheon is parted, couped, or quartered with diverse coats of arms, the French call the uppermost *le-tout-du-tout*. This mode was practised in the achievement of the Princes of Orange, of the family of Nassau, before their late elevation to the kingly rank; thus, quarterly, 1st, *azure semée of billets, a lion rampant or*, for Nassau. 2d, *Or a lion rampant guardant gules crowned, langued, and armed azure*, for the country of Catzellenbogen. 3d, *Gules a fess argent*, for the house of Vianden. 4th, *Gules two leopards or langued and armed azure*, for the country of Dietz. Over all an inescutcheon by way of *surtout*, quarterly. 1st and 4th, *Gules a bend or*, for Shallon. 2d and 3d, *Or a hunting horn azure virole and stringed gules*, for the principality of Orange: which inescutcheon is again surmounted by another by way of *le-tout-du-tout*, viz. *cheque or and azure of nine points* as a coat of pretence for the city of Geneva.

Moreover, in foreign heraldry, the quarters are often divided by the *pale* or the *fess*, which ordinaries are then again charged with escutcheons. And the ordinary of the cross is often used in this very way by ourselves, as in the arms of the St Clairs, Earls of Caithness, who bear *quarterly*, 1st, *azure, a ship at anchor*, &c. for the earldom of Orkney. 2d and 3d, *Or a lion rampant gules*, for the name of Sparr. 4th, *azure a ship under sail*, for the title of Caithness; and, *over all dividing the coats a cross engrailed sable*, for Sinclair.

The third way (Fig. 9.) is by *tiercing* and *engrafting*, (by the French called *Entée*,) an instance of which is to be seen in the arms of the King of Great Britain, whose paternal escutcheon is, 1st, The arms of Brunswick, *gules two lions passent guardant or*, impaled with those of Lunenburg *or semée of hearts*. Gules a lion rampant azure armed and langued as the hearts, and *grafted by way of entée between the impaling in point;* the arms of Lower Saxony *gules a horse current argent;* or, more shortly, *Brunswick and Lunenburgh impaled with ancient Saxony entée en pointe.*

The fourth and last method proposed for marshalling of arms, is by dividing the shield into a plurality of areas or quarters by many partée and coupée lines, which when drawn appear like the areas of a chequer, divided by perpendicular and horizontal lines. (Fig. 10.) By this method any number of coats may be brought in; but it seems to be agreed by the best authors, that the number of *marshalled arms* in one shield should not exceed six or eight quarters at most, and these always charged on the warrantable grounds and reasons of the bearer having many territories or feus, or matching with heiresses, or as arms of alliance or pretension. The Germans, it is true, are in use to accumulate twenty or thirty coats in one shield; but this is always on account of their many territories or feus, to shew how many votes they have in the circles of the empire. The French also have many quarterings, though not so many as the Germans, their feus being neither so many nor so free, and the whole succession of these dignities belonging always to the eldest son, whereas in Germany the younger brothers share with the eldest in the dignity and titles of honour of the family. In Scotland, the prejudices of the heralds seem always to have run very strong against many quarterings, in so much that few have followed the example set them by Queen Mary of Lorraine, whose rich and loaded escutcheon is still to be seen in many parts of the kingdom, impaled with the simple bearing of her husband James V.; almost the only instances of the sort being found in the arms of those Englishmen who were honoured with Scots titles after King James VI. succeeded to the crown of the sister kingdom.

The several ways whereby the quarterings to which a family may be collected and marshalled in one achievement, after the English method, are explained in the annexed scheme, to which the reader is referred.

No. I. Suppose the heir of the WILLOUGHBYS to have married the heiress of LATIMER, NEVIL, and BEAUCHAMP, which three coats the heir of Willoughby has an undoubted right to quarter with his own paternal coat.

No. II. Shews how WILLOUGHBY, in consequence of this marriage, may inherit the blood, and become entitled to quarter the arms of no less than fifty-six families: thus, as WILLOUGHBY by this marriage hath a right to quarter LATIMER, so LATIMER had before a right to quarter *Blyke*, who quartered *Brocton* and *Filylode; Astley*, who quartered *Fynes* and *Thynne; Darrel* and *Cheney*, who quartered *Boyle* and *Wilmot*. Secondly, TWENGE, who quartered before *Bulmer*, who quartered *Mallet* and *Beke;* and *Bruss*, who quartered *Fitchet* and *Dean*.

The like as to NEVIL and BEAUCHAMP, and the quarterings by them brought in.

No. III. Supposes THOMAS PYE to be the son and heir of Thomas Pye, and Elizabeth his wife, heiress of John Abbot, whereby he becomes entitled to quarter the arms of sixteen houses; eight by the father's side, and as many by the mother's.

No. IV. is formed upon a plan more extensive than either of the former, and shews how a person may in five descents be heir to thirteen families; so that we can no longer wonder at seeing two hundred coats borne in one achievement.

*Schemes shewing how Quarterings may be Collected and Marshalled.*

No. I. WILLOUGHBY marries the Heiress of . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . .

## No. III. PYE'S PEDIGREE.

John Nevil = Alice, daughter and heiress of Maudit

Mary, D. and heiress = Thomas Moore

Joan, D. and heiress = John Scrope

Elizabeth, D. and heiress = Thomas Morley

Anne, D. and heiress = James Golding

Harriet, D. and heiress = John Croft

Margaret D. and heiress = Thomas Pye

Abr. Cranfield = Joan, heiress of Pool

Th. Tomkin = Harriet, D. and heiress.

Joesph Caldwell = Margaret, D. and heiress

B. Thornton = Amy, D. and heiress

T. Beauchamp = Anne, D. and heiress

John Finch = Elizabeth, D. and heiress

John Abbott = Mary, D. and heiress

Thomas Pye, only son and heir = Elizabeth, sole daughter and heiress

Thomas Pye, only son and heir.

## No. IV. WARREN'S PEDIGREE.

John Catline = Maud, heiress of Story

John Gray = Anne, heiress of Sloper.

John Warren = Anne, heiress

Thomas Owen = Ellen, heiress of Roper.

Thomas Pulford = Alice Etton.

Thomas Gray = Joan Ely.

Thomas Green = Maud, heiress of Pylewell.

John Warren = Alice, heiress

Thomas Griffith = Joan, heiress of Thomson.

Thomas Pulford = Anne, heiress.

Thomas Green = Joan, heiress of Newton.

Thomas Warren, only son = Jane, heiress.

Tho. Pulford, only son = Jane, heiress.

John Warren only son and heir, = Alice, daughter and sole heiress.

John Warren, only son and heir.

The most approved method of marshalling arms in an achievement of this species is the following: "Begin with the arms of the first heiress who married into the family, and next to them place the several coats which she brought in; then proceed to the second heiress, and those which she brought in; and so on to the rest, without any regard to the rank or station of any of these heiresses before their marriage." Nevertheless, when the royal arms are brought in by any match, it is usual to give that match the second quarter, next to the bearer's paternal coat. Nay, some place it in the first, and the paternal coat in the second quarter. The achievement composed in this way is most properly termed by Edmonstone, "The genealogical pennon."

*Of the External Ornaments of the Shield.*

35. In the first part of this article, wherein we have attempted to trace the origin of armorial bearings to the tournaments of the middle ages, a passage is quoted from the treatise of King René of Anjou, in which the knights who propose to tilt at any tournament, are required to make display of their coats of arms some days before the lists are opened, with their helmets, crests, and other marks of their condition or dignity. In the MS. treatise of John Caxton, preserved in the Advocates' Library of Edinburgh, it is said, that "no man shall wear his cognisaunce on a close basnet, except he has carried arms within the lists and barriers of military exercises." From these passages, and many others of a like nature in the old authors, it seems reasonable to conclude, that after the bearing of shields had begun to be common in Europe, the great nobility and gentry, entitled by their descent to partake in the courtly tournaments of the times, were willing to adopt some method of distinguishing themselves from the herd of those who bore coat-armour, and for this purpose introduced the practice of adorning their shields on seals, &c. with a representation of those helmets, crests, and other articles of apparel, which they were themselves accustomed to wear upon those solemn occasions, and to which those of humbler birth could, it was believed, make no pretension. In process of time, the example of these military nobles was imitated by others, who thought themselves entitled to equal respect, although for different causes. Civil rulers adorned their shields with coronets, consular capes, batons, and such like signs of dignity; and the churchmen were not slow to make the same parade of the symbols of their office. The papal tiara, the cardinal's hat, the patriarch's cross, the mitre, the crosier, and the keys of St Peter, were associated in strange union with the family emblems of worldly honour and advantage, such as a free feu, a feat of chivalry, or a wealthy marriage.

*Of the Helmet.*

36. This ornament in heraldic representations has many varieties of matter, form, and situation.

In Germany, by an imperial edict, helmets of gold belong to sovereign princes, of silver to the high nobility, and of steel to gentlemen.

The French heralds have settled every thing respecting helmets according to these rules.

The helmets of emperors and kings are all of gold damasked fronting, (*tarre de front*,) open without bars or vizor.

Dukes, marquisses, and counts, have silver helmets, damasked with gold, fronting with nine bars, *grille et mise de front*.

Viscounts, barons, and knights, have silver helmets, with gold edges in profile, with seven bars.

Esquires have helmets in profile, with five bars in the guard vizor.

Gentlemen of three descents, a helmet in profile, with three bars.

The English and Scots have their helmets somewhat different.

A gentleman, or esquire, has his in profile close.

A knight has a full-faced steel helmet open.

Earls, viscounts, and barons, have profile steel helmets, with gold bars, &c.

Dukes and marquisses have the full-faced helmet of steel, with five bars of gold.

The king, and princes of the blood-royal, have the full-faced helmet, with six bars, all of gold damasked.

*Of the Ornaments of the Helmet.*

37. The MANTLING, LAMBREQUIN, HELM-DECKEN, or VOLET, is probably a representation of the hood or covering, intended for protecting the helmet in rain, &c. and its ragged form derived from the cuts which that integument must have sustained in battle. (See Plate CCXCIII. Fig. 11.) These ornaments are called *hachements*, from the Italian *azzimare*, (*caput ornare*.) or *ingemmare*. In the *patois* of Picardy, *achemer une epousee*, is still used for *to arrange the bride's head dress*. The *Lambrequin* seems, in old times, to have been ornamented with the bearings of the wearer, for King René speaks of it as "armoyé des armes de celui qui le portera;" even at present it is generally of the *tincture of the field*, in foreign heraldry. Behind the shield itself hangs the manteau, mantle, or cloak, in Latin *chlamys*. In this country the mantles of gentlemen and knights are red without and white within. Those of the nobles red, doubled up with rows of ermine, according to their degrees. The king's mantle is of gold, lined with ermine.

*Of the Wreath, &c.*

38. Menestrier, speaking of this ornament, says, "that some hundred years ago the French nobility used garlands of twisted silk, with which they kept fast on their heads their hoods or capes, as may be seen in the pictures of the old Dukes of Burgundy," &c. These wreaths were commonly of the *colours of the lady** of the bearer. The wreath is now always of the colour of the shield. See Plate CCXCIII. Fig. 12.

*Of the Crest or Cimier.* (See Fig. 13.)

39. This ornament of the helmet seems to have been very early in use among the Greeks or Romans. After its introduction among the moderns, the use of it was long restricted to sovereign princes and military commanders. But in imitation of King Edward III. (the first English prince who wore a crest,) the knights of the garter, and afterwards, by degrees, all the bearers of coat armour adopted crests. The crest is first seen on a seal of Philip Earl of Flanders in the year 1101.†

Though crests are hereditary, yet a greater latitude is allowed respecting them than any of the essential parts of armoury. They are looked upon somewhat in the nature of devices, and accordingly are varied by the caprice of individuals, so that the sons of the same family often wear different crests.

*Of the Motto, Cry of War, and Device.*

40. The *Motto* is a short sentence placed in a scroll above the crest, very often allusive to it, or to some part of the bearings. If it alludes to the crest, the two together form what is called *a complete device*; as in the case of Stewart, Earl of Galloway; the crest *a pelican vulnered feeding her young*; the motto "*virescit vulnere virtus*." Kirkpatrick of Closeburn has for crest a hand grasping a dagger; motto, "I'll make sicker," alluding to the remarka-

* Here take thy lover's token on thy pate. SPENSER, *Fairy Queen*, 1. 6. 47.

† Had Mr Campbell been acquainted with heraldry, he would never have written

*A meaner crest upon his* SHIELD. O'Connor's Child.

ble feat of his ancestor, who slew the Red Cummin in the days of Bruce and Baliol. Often they have no such relation, and merely express some predominant passion of piety, love, or war, of the first who assumed them.

Camden tells us that the earliest instances of mottos painted on shields, which he had met with in this island, were those of William de Ferrariis, Earl of Derby, who carried round his escutcheon, *vair with a bordure of horse shoes*, "Lege, Lege;" and Sir Thomas Cavill, who bore for arms *a horse*, under which was written "Thomæ credite cum cernitis equum ejus:" these are both of the age of Henry III. The more abundant use of mottos was, without question, owing to King Edward III. who having founded the order of the garter, and given it the motto "*Honi soit qui mal y pense*;" each of the original knights of that order took to himself a motto of his own choice, and put it under his arms. From that period the fashion grew more and more in vogue, as may be seen from the accounts which we have of the standards and pennons of the noblemen and gentlemen, both of England and Scotland, particularly during their French wars.

N. B. Women wear neither crests nor mottos.

The *cry of war* was the battle shout of the house; and was also worn in a scroll, as the "Mountjoye St Denys" still is over the pavilion of the French king. Many families have, in consequence of the change of manners, retained these cries of war as mottos. Of old they consisted very often of the name of the noble, as "A Home! A Home!" "A Douglas! A Douglas!" &c.

*Of Devices.*

41. The *Device Proper* is a badge or emblem independent of any part of the family bearing; the legitimate descendant of the emblems of the ancients. The device is always assumed by the bearer personally, and either may or may not be the same, or that of his ancestor, as he pleases. The roses, red and white, were the *devices* of York and Lancaster. The portcullis was a device belonging to the Beauforts (descended from John of Gaunt, fourth son of Edward III.) and carried as such by the Jameses of Scotland. The said John of Gaunt, when he pretended a right to the crown in the reign of Richard II. adopted for his device "an eagle standing on a padlock assaying to force open the same." This was a strictly personal device. From these *devices* of the kings, some of the English pursuivants derived their names, as *Portcullis*, *Falcon*, &c.

*Of Supporters.*

42. These likewise are exterior ornaments, being placed on the sides of the achievement as matters of embellishment, and formally to timbre or support it. Menestrier assures us that they had their origin from tilts, tournaments, and justings. "On these occasions," says he, "it was usual for the knights to have those shields of their arms, (which we have already seen they were obliged publicly to display some days before the opening of the lists), guarded by their pages, armour-bearers, or other attendants, clothed in fancy dresses, sometimes making them appear as savages, Moors, Saracens, lions, &c. The business of these *supporters of the shield* was to take notice who, by touching the shield, accepted the challenge of their master." This custom was revived with perhaps greater magnificence than was ever before known, at a tournament in Paris before Louis XIV. in which the esquires who attended the nobles entering the lists, were dressed in the most superb manner that art could invent, representing Moors, Persians, Armenians, Turks, &c. &c. From these attendants thus disguised many heraldic writers bring the use of supporters, which, say they, every one who (being noble or gentle by father or mother's side) was admitted to tourney, had ever after a right to carry.

This doctrine is, however, strongly combated by many able writers, and particularly by the celebrated John Anstis, in his curious manuscript treatise, entitled *Aspilogia*, (now in the Astle collection,) who has these observations.

"In these later ages, the nobility have been distinguished from persons of inferior rank, by having supporters and coronets cut on their seals; but, as far as I am able to observe, there was not anciently any particular mark in the seals of the nobility that differenced them from the knights. As to supporters, they were, I take it, the invention of the graver, who, in cutting on seals shields of arms which were in a triangular form, and placed on a circle, finding a vacant space at each side, and also at the top, thought it an ornament to fill up these spaces with vine-branches, garbs, trees, flowers, plants, ears of corn, feathers, fret-work, lions, wiverns, or some other animal, according to his fancy.

If supporters had been esteemed formerly, as at this time, the marks and ensigns of nobility, there could be no doubt but there would have been then, as now, particular supporters appropriated to each nobleman, exclusive of all others; whereas, in the seals of noblemen affixed to a paper addressed to the Pope, A. D. 1300, the shields of arms of twenty-seven of them are in the same manner supported (if that term may be used) on each side by a wivern, and seven of the others by lions. John de Hastings hath the same wivern on each side of his shield of arms, and also on the space over it, in the same manner as is the lion in the seals of *Hache*, *Beauchamp*, and *De Malolacu*. The seals of Despencer, Basset, and Badlesmere, pendent to the same instrument, have each two wiverns or dragons for supporters; and that of Gilbert de Clare three lions placed in the manner above mentioned. The promiscuous use of wiverns to fill up the blanks in seals, is obvious to all who are concerned in these matters.

But what is a stronger argument is, that the same sort of supporters are placed in the seals of divers persons never advanced to the peerage. Instances of this kind are often met with; nay, the engraver hath frequently indulged his fancy so far, as to insert such figures as do not seem proper, according to our present notions of supporters of arms; as *two swords* on each side the arms of Sir John de Harcla; and *St George fighting with the dragon* on one side, the *Virgin with our Saviour in her arms* on the other side of a seal affixed to a deed of the Lord Ferrers, whose arms on the impress of a seal pendent to a deed of the 17th May, 9 Henry VI. have not any supporters.

When supporters were assumed, if there were two on one seal, they were generally the same; but sometimes there was only one, and at other times three, as may be seen on various seals."

"After having considered the observations of Mr Anstis," says Edmonstone, "I am persuaded that not a doubt can remain of supporters having originated from the fancy of seal engravers. However this may be, it is certain, that in England supporters were of old worn by many persons of the commons. All those, particularly, who bore offices of dignity in the state, as the lord deputy of Ireland, the lord of the marches of Wales, the warden of the stannaries, &c. and even by families altogether in private life; as the Stevenings of Sussex, the Stawells of Somerset, the Wallops of Hants, Savage of Cheshire, &c.; and certainly the supporters still worn by the descendants of some of these families, rest on a much more honourable foundation than any modern grant of supporters that can be obtained from a college of arms."

It is worthy of remark, that supporters were formerly changed very frequently, according to the choice of individuals, and by no means considered as fixed and unalterable marks of descent, like the proper armorial bearings. From King Edward III. till James I. few of the English kings wore the same supporters as their predecessors. The lion, the falcon, the hart, the antelope, the swan, the leopard, the bull, the boar, the greyhound, the dragon, and the eagle, were all successively used by the monarchs of England; and one of them, (Edward IV.) altered his no less than three times. Edward VI. was the first who bore the lion crowned with the imperial crown. This was retained by Mary and Elizabeth; and James also used it as his dexter supporter, placing the Scottish unicorn* on the left side; on which arrangement, no alteration has been made by any of his successors.

Henry VIII. was the first king of England who formerly granted supporters to the peers of the realm. He gave the like ornaments to the knights of the garter and of bath. The kings of arms in England are authorised to grant supporters to all persons not under the degree of a knight of the bath; and whoever of an inferior rank bears supporters in that kingdom, does so by an express grant from the crown.

In Scotland, the right to bear supporters is commonly supposed to rest on somewhat a different footing. Some of the baronets of Nova Scotia have taken up the notion, that they are, by the terms of their patents, entitled to add supporters to their paternal coats, and they accordingly wear them in their armorial ensigns. But an impartial consideration of the clause in the patents will convince them of their mistake, more particularly as it is not pretended, that there ever was any other royal grant or warrant issued, whereon they can found a claim to any such privilege. In the patents previous to the year 1629, it is ordained, "that the baronets and their heirs-male shall, as an addition of honour to their armories, bear, either on a canton or inescutcheon, at their option, the ensign of Nova Scotia, being *Argent, a cross of St Andrew azure charged, with an inescutcheon of the royal arms of Scotland, supported on the dexter by the royal unicorn, and on the sinister by a savage or wild man proper*," &c.; all evidently referring to what is within the canton or inescutcheon, and not to any exterior ornaments of the baronet's own shield, of which the said canton or inescutcheon is henceforth to form a part. As for the patents posterior to the year 1629, the whole of the clause just quoted is omitted, and the patentee is not allowed to carry a canton or inescutcheon of honourable augmentation to his coat; but, in lieu thereof, "*around his neck an orange tanny silk ribbon, whereon shall be pendent in a scutcheon argent, a saltier azure, therein an escutcheon of the arms of Scotland*,"† &c. This alteration, in all probability, took place on account of the manifest impropriety of blazoning supporters, mottos, &c. on a canton or inescutcheon; an objection which could never have occurred, had the construction which has been put on the clause of gift been the proper one.

During the reign of Charles II. a letter was addressed to the Lyon-office, strictly prohibiting any grants of supporters to persons under the degree of nobility. But many of the old barons of Scotland, (and particularly *the chiefs of names*,) who had always been in use to sit in parliament in their own right, and who with justice considered themselves as inferior in degree indeed, but as members of the same order with the titled Lords of Parliament, protested with great zeal against being obliged to discontinue the use of those supporters which had been borne by their ancestors for several centuries, and originally retained, either as the marks of the patriarchal superiority over their clansmen, or in consequence of some feat of skill or valour in tournament or in battle. The matter was not pressed, and these families have continued their supporters ever since without any objection being made. Of later years, however, a much more questionable extension has been given to the use of supporters. From whatever cause the laxity may have arisen, the fact is certain, that we have seen supporters assumed by persons who, so far from having any claim to being descended from the old barons who had power of *pit* and *gallows*, and were in reality the nobles of Scotland, as much as either dukes, marquisses, or earls, are sprung from the very dregs of the people, and are in truth the very men, to guard against whose presumption and insolence was one of the first great objects for which a college of heralds was instituted in this country. The utmost latitude which can be given to the interpretation of the law on this head, either as it is expressed in the King's own words, or as it has been modified by the practice of the heralds, is, that those of the lesser barons, who can shew proofs, by old seals or otherwise, of their ancestors having borne supporters previous to the passing of the act, 10th September, 1672, are *excepted from the general rule*, and permitted to carry supporters. The letter above referred to was quoted by the Lord Lyon himself, as *his authority for refusing supporters* to persons of rank very different from most of those who have of late procured these ornaments by the good offices of his successors.

> ——*At titulos* Regina PECUNIA *donat,*
> *Et genus, et proavos, sordesque parentis honestat.*
>
> SECTANUS.

No women have a right to bear supporters, except those who are peeresses by descent or by patent. If they are peeresses by patent, they have in consequence a grant of supporters to themselves and their heirs-male; if by descent, they retain the ancient supporters of the barony, to which they have an indisputable right, in as much as they represent peers whose insignia and titles are all through them to descend to their posterity.

### *Of Crowns and Diadems.*

43. Crowns or coronets may be used in armorial bearings in four different ways.

1*st*. As essential or internal parts of arms, that is, when they are the chief figures of the escutcheon, as the three crowns in the shield of Sweden. Many families throughout all the European kingdoms bear similar arms; and crowns so worn are no marks of sovereignty or dignity, of whatever form they may be.

2*dly*. When they are used as additional charges, or ornaments within the shield, they are in like manner no marks of sovereignty or dignity.

3*dly*. When crowns are placed upon helmets, which *timbre* coats of arms, they are then marks of dignity, being commonly so placed by sovereign princes. Yet many gentlemen who have no pretensions to such rank bear crowns on this way in their helmets, a custom which, according to Menestrier, is derived from the tournaments, "especially those solemnized in Germany, where knights were allowed to adorn their helmets in that manner, in memory of their

* The unicorn was originally, with great propriety, assumed by the Scottish kings, in allusion to the words of Scripture, Job xxxix.—"Canst thou bind the unicorn with his band? Will he be willing to serve or abide by thy crib?"

† Vide Fountainhall's *Decisions*, MS. (in the Advocates Library) p. 17. This important document was pointed out by John Riddell, Esq. advocate, a gentleman whose attainments in every part of the antiquarian learning of his country are above all praise.

having been exercised in such disports." And though indeed there are many helmets placed over the German coats, according to the number of feus, whereby the bearers voted in the circles of the empire; yet we see but few of them adorned with crowns, which, according to our author, can only be explained by supposing that some of these feus are not privileged to carry a crown, the ancient possessors of them not having been present at the tournaments.

*4thly*. Crowns placed immediately above the top of the escutcheon, are ensigns of sovereignty or nobility, whereof the degrees are set forth by their shapes. The arched crowns topped with *monds* were first introduced by the emperors, and from that circumstance are called imperial crowns, although now worn by all the kings in Europe, since Charles the Eighth of France assumed an imperial crown, in token probably of his pretensions to the empire of the East.

"The imperial crown of England is composed of four crosses pattee, and as many fleur-de-lys of gold placed on a rim or circlet of gold, embellished with precious stones. From these crosses arise four circular bars, ribs or arches, which meet at the top in form of a cross; at the point of intersection whereof is a pedestal, whereon is a mound. On the top of the mound is a cross of gold, all embellished likewise with precious stones, and three very large oval pearls; one of them being fixed in the top, and two pendent at the transverse beams of the cross. The cap within this crown is of purple velvet, lined with white taffeta, turned up with ermine. See Plate CCXCIV. Fig. 1.

The crown or coronet of the Prince of Wales resembles the king's crown, save only that it hath not four arches, but two only. See Fig. 2.

The younger sons of the king bear coronets, composed of crosses pattee and fleur-de-lys.

A duke (not of the blood-royal) has a circle of gold, with eight leaves of equal height above the rim, commonly called strawberry leaves, the whole richly chased; a crimson velvet cap, turned up with ermine of one row, and topped with a golden tassel. See Fig. 3.

A marquis has a circle of gold, with four leaves placed between four pearls, raised on points of equal height with the leaves. See Fig. 4.

An earl has eight pearls raised on as many points, between every two points a strawberry leaf lower down. See Fig. 5.

A viscount has pearls to the number of twelve or sixteen, placed on the edge of the rim. See Fig. 6.

A baron has only six pearls placed on the rim of his golden circle. See Fig. 7.

*Of the Cap of State.*

44. This cap is of crimson velvet, faced with ermine, with two points turned to the back.

Of old, by the practice both of England and Scotland, this cap was borne by princes or dukes only, as an ensign of dignity, whether on the helmet itself, or timbring the whole achievement. Mr Sandford, in his *Genealogical History of the Kings of England*, informs us "that King Edward III. and his successors, as low down as Edward VI. had on their seals of arms this cap of state. For on one side is always to be seen the figure of the monarch on horseback and in armour, with this cap of state on his head, and the crest of England set thereon."

The cap was originally therefore granted to certain nobles on account of pre-eminent dignity or merit, as we find in the case of Henry II. Duke of Lancaster in England, and Archibald Earl of Douglas, Duke of Torraine, and Great Constable of France, whose seal, affixed to several charters still extant in Scotland, always represents the helmet as adorned with this cap. But now the cap of state hath lost all its former eminent dignity by the evil usage of certain heralds, and is now borne not only by all degrees of nobility, but by many of the inferior gentry, and indeed by some of the lowest extraction. See Fig. 8.

*Of Ensigns belonging to Ecclesiastical Dignities.*

45. The Pope carries his arms in an oval shield or cartouche, which form has become common in Italy, in consequence of other ecclesiastics imitating their chief. This shield is adorned externally with the ensigns of his dignity, which are, 1st, *The Tiara*. This is an high cap, or mitre, of silk, environed with three crowns of gold, and topped with a mound and cross like the imperial crown. This triple crown (or as it is called by the Italians the *regno*) is the sign of his supremacy, and placed over the cartouche. See Fig. 9.

*2dly*. The keys, one of gold, and one of silver, (symbols of the Pope's power of opening and shutting the gates of Paradise) are placed in saltier behind the cartouche.

*3dly* The staves. The two angels which support the proper arms are placed in a sitting posture, one on each side of the cartouche; each with one hand upholding the *regno*, and with the other grasping a long staff, having three traverses near the top; which traverses end in trefoils, and are of the same metal with the keys.

The cardinal's external armorial mark of dignity is the *red hat*, with which they timbre their shields, having red strappings, with fifteen tassels hanging down at each side of the shield. Innocent III. charged the cardinals to discontinue all symbols of secular dignities; but this was never complied with except by the Italians.

Archbishops of the Roman church, primates, and legates, place a cross staff with two traverses in pale behind the shield, and above the same a green hat with ten tassels hanging down on each side.

Our modern archbishops in England place a mitre *affrontée* on the top of the shield, (Fig. 11.) issuing from a ducal coronet, and having two labels or pendants hanging from it, and behind the shield two crosiers in saltier. Bishops use their mitre alone, proceeding from a plain circlet of gold, without any other exterior ornaments.

Abbots of the Roman church use a mitre in profile, and a crosier in pale behind the shield; above both a black hat with a knotted cord, and six tassels on each side, as may be seen in many of our Scottish abbeys, such as Holyroodhouse, Paisley, &c. Priors, provosts, deans, and chanters of the church of Rome, are all distinguished by similar marks, such as palm-branches, pastoral staves, &c.

*Ensigns of Civil and Military offices.*

46. In France and Germany, it has always been the custom of the great civil officers to denote by some exterior ornament of the shield their station and dignity. In Scotland likewise this practice was common before the union; but in spite of the unceasing endeavours of the heralds of England, the great officers of that kingdom have never complied with the customs of their brethren in the other European states. The only established civil officer in England who is distinguished by any armorial ensign of his official dignity, is the Earl Marshall, who carries behind the shield of his arms *two batons in saltier sable, the ends gold.* When there is a deputy Earl marshall, he is permitted to carry *one baton in bend dexter*, exactly as was used in Scotland.

The chancellor of Scotland bore behind his shield *two maces in saltier, ensigned with imperial crowns*; as also under the shield *a purse* with the strings open, *pendant*, *fretted*, *nowed*, buttoned, and tasselled gules, embroidered with the royal arms.

In addition to these, the chancellor of France has a proper cap of gold, (*mortier d'or*) turned up ermine on the helmet.

The presidents of the parliaments in France had in the same way their proper cap of black velvet edged with gold galloon.

The lord high chamberlain in Scotland had two keys disposed in saltier behind his shield, in the same manner as the *grand chambrier* of France.

The justice general of Scotland carried two naked swords in saltier behind his shield, the points being upward.

The lord high treasurer in Scotland carried a white staff ensigned on the top, with an imperial crown in pale behind his shield.

The office of cup-bearer being of old hereditary in the house of Southesk, these Earls carried a golden cup in their arms.

The king's foresters carried hunting horns; as Burnet in the northern forest, and Forester of that ilk, in the southern. So did the *grand veneur* of France.

The *grand pannetier* of France carries under his arms a rich cover and knife and fork in saltier.

The lord high constable of Scotland carries *on each side of the base part of his shield, an arm gauntletted fessways, issuing out of a cloud, and grasping a sword erected in pale at the dexter and sinister sides of his shield, all proper hilted and pomelled* OR.

In France many other exterior marks of the same sort were in use, all sufficiently intelligible without previous description, as the grand master of artillery, who carried under his arms *two field pieces*, &c.

But in no kingdom were either external or internal ensigns of dignity so extensively used, or so systematically arranged, as in France, during the empire of Napoleon. Not only were princes, grand dignitaries, dukes, counts-senators, counts-archbishops, counts-military, barons military, baron-bishops; and chevaliers, distinguished by mantles, lined in different manners; but for each of these ranks of persons there was set apart some one of the honourable ordinaries, which, either by its charge, its colour, or its position, immediately denoted that order in the state to which the bearer belonged: Thus the princes grand dignitaries had a chief of azure charged with bees of gold; dukes, a chief of azure charged with stars of silver; counts-senators, a canton dexter azure charged with a mirror in pale *or*, in which a serpent wreathed argent regards itself; counts-archbishops, on a canton dexter azure a cross patee *or*; counts-military, on a canton-dexter azure, a sword erect in pale *argent* mounted *or*, &c. The canton dexter always denoted a count, the canton sinister a baron. Chevaliers of the legion of honour placed the cross of their order on any one of the nine honourable ordinaries which they preferred. In this heraldry supporters are entirely laid aside, and the nobility, under the rank of princes, are distinguished by the number of feathers in the plume of the bonnet with which the shield is timbred. See Plate CCXCIV. Fig. 12. shewing the *Arms of a Duke* under Napoleon.

*Of Ensigns of Chivalry or Knighthood.*

47. Knights of the different sovereign orders in Europe are in use to surround their shields with the collars of their orders; and if any one has more orders than one, the collar of the most ancient order ought of right to be placed nearest the shield. In Britain, however, it has become the practice for knights of the garter to place their shields within the garter itself, not the collar of the order, and always to give this most dignified order the preference over every other, by assigning to its ensign the place of honour nearest to the escutcheon. For a particular account of the several orders now so much in vogue among the sovereigns of Europe, see the article KNIGHTHOOD.

*Of the Compartment.*

48. The compartment is that figure, on which the shield and supporters usually rest. When the bearer has more mottos than one, if one of them relate to the supporters or figures of the shield, it should be placed in the compartment; if one relate to the crest, it should be in an escrole thereupon. Heralds agree, that the compartment is in general intended to represent the lands or feu of the person below whose shield it lies, although it be sometimes granted or assumed in memory of some remarkable action. An instance of the compartment thus applied, is to be found, says Nisbet, "in that of the Earls of Douglas, who obtained the right of having their supporters placed within a *pale of wood wreathed*, because the Lord James, in King Robert Bruce's time, defeated the English in the forest of Jedburgh, and, that they might not escape, caused wreath and impale that part of the wood, by which he conjectured they might make their escape." The territorial compartment may, in like manner, be illustrated from the same family. William, first Earl of Douglas and Mar, has "a compartment like to a rising ground, with a tree growing out of it, and semée of hearts, mullets, and cross crosslets, the armorial figures of this Earl's escutcheon, to shew that the compartment was meant to represent his lands and feus." Others seem to have assumed a compartment from more fanciful motives; as the old Earls of Perth, who had a green hill semée of galtraps, which, with their motto "Gang warrily," forms a complete device.

*Of the Pavilion.*

49. After treating of these external marks of honour common to the nobles of the European kingdoms, it remains to take notice of one entirely confined to sovereign princes, although not assumed by all of them, viz. the pavilion. This is a tent or tabernacle, with a canopy roof, under which the arms of the emperors, of the kings of France, and of some other princes, are usually represented. Menestrier is of opinion, that the first who invented this use of the pavilion was Philip Moreau, and that from its having made its first appearance on the coins of Philip of Valois, it derived the name by which we know it. As a specimen of the mode of blazoning arms, we have inserted the royal achievement of Scotland, in Plate CCXCIV. Fig. 13. in which the blazon, according to Mr Nisbet, runs thus: "The sovereign ensign armorial of the kingdom of Scotland—*or* a lion rampant *gueules*, armed and langued *azure*, within a double tressure counter flowered with flower de lysses of the second; timbred with a helmet affrontée with bars *or*, adorned with lambrequins *or*, doubled ermine, and ensigned with the imperial crown of Scotland; and thereon for crest a lion sejant full-faced *gules*, crowned *or*, holding in his right paw a naked sword proper, and in the sinister a scepter *or*, both erected; and above, in an escrole, the motto "IN DEFENSE." The shield is encircled with the colour of the most noble order of the thistle, with its badge thereto appended of gold, enamelled azure, having the image of St Andrew surmounted of his cross argent; and supported by two unicorns argent,

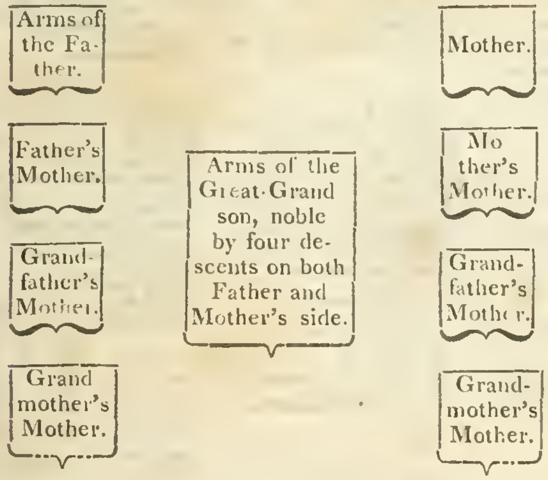
crowned with imperial and gorged with open crowns, to the last chains affixed passing between their fore-legs and reflected over their backs *or*; he on the dexter bearing up a banner *or*, charged with the red lion of Scotland; he on the sinister, a banner azure charged with the white cross of St Andrew, both standing on a compartment cheque or and azure like a pavement, on the first the lion of Scotland, and on the second St Andrew's cross. All within a royal pavilion of cloth of gold, semée of thistles slipped proper, doubled ermine, the comble or canopy rayonnée, and adorned with precious stones, and topped with the crown of Scotland, over all on an escrole the device of Scotland (alluding to the thistle,) "NEMO ME IMPUNE LACESSET."

### *Of Funeral Escutcheons, &c. in Scotland.*

50. Although our code calls no man noble under the degree of a baron, yet there is an old and well known distinction between *nobiles majores* and *nobiles minores*: the first comprehending all titled nobles from the prince to the baron; the second, all between the baron and the gentleman inclusive.

A gentleman is one descended of three descents of nobles (viz. of name and arms) by both father and mother, for gentility is not perfect in the person who first obtains arms among us, or letters patent of noblesse on the continent; as, among the Romans, though the father was free born, and of the equestrian census, yet it was requisite that the grandfather should be so also, otherwise the son could not obtain the *annulus*, or symbol of the equestrian rank. Gentility, then, begins in the grandfather, increases in the father, and is perfect in the son.

The proofs of this nobility are the armorial ensigns or gentilitial tesseras of these ancestors, arranged in due order on the sides of the escutcheon, (and therefore fitly here treated of among the external ornaments of the shield), not indeed commonly, but on particular occasions, as on that of the funeral of the bearer. The arrangement of these tesseræ is the same, to whatever number they amount. If the nobility be of four descents or lineages, the mode of arrangement is as follows:



The full funeral escutcheon of the Duke of Athole is represented in Plate CCXCIV. Fig. 14.

In England, the place of this genealogical escutcheon is supplied by the genealogical pennon before described in p. 339.

### *Of Precedency.*

51. It is, as was formerly observed, the part of the *heralds* to settle the order or precedency of all those assembled in public meetings. The rules by which the precedency of individuals is ascertained, seem to be more fixed and determinate in England, than with us of Scotland. Sir William Blackstone, in his *commentaries on the law of England*, book i. chap. 12, gives a Table of Precedence, which is here copied as the most safe authority.

## TABLE OF PRECEDENCE.

The King.
The King's Children and Grand-children.
——— Brethren.
——— Uncles.
——— Nephews.
The Archbishop of Canterbury.
Lord Chancellor or Keeper, if a baron.
Archbishop of York.
Lord Treasurer. } If Barons.
Lord President of the Council. } If Barons.
Lord Privy Seal. } If Barons.
Lord Great Chamberlain. } Above all peers of their own degree.
Lord High Constable. } Above all peers of their own degree.
Lord Marshall. } Above all peers of their own degree.
Lord Admiral. } Above all peers of their own degree.
Lord Steward of the Household. } Above all peers of their own degree.
Lord Chamberlain of do. } Above all peers of their own degree.
Dukes.
Marquisses.
Dukes eldest sons.
Earls.
Marquisses eldest sons.
Dukes younger sons.
Viscounts.
Earls eldest sons.
Marquisses younger sons.
Secretary of State, if a Bishop.
Bishop of London.
——— Durham.
——— Winchester.
Bishops.
Secretary of State, if a Baron.
Barons.
Speaker of the House of Commons.
Lords Commissioners of the Great Seal.
Viscounts eldest sons.
Earls younger do.
Barons eldest do.
Knights of the Garter.
Privy Counsellors.
Chancellor of the Exchequer.
Chancellor of the Duchy.
Chief Justice of the King's Bench.
Master of the Rolls.
Chief Justice Common Pleas.
Chief Baron of the Exchequer.
Judges and Barons of the Coif.
Knights Bannerets Royal.
Viscounts younger sons.
Barons do. do.
Baronets.
Knights Bannerets.
Knights of the Bath.
Knights Bachelors.
Baronets eldest sons.

Knights eldest sons
Baronets younger do.
Knights do. do.
Colonels.
Serjeants at law.
Doctors (of Divinity, Law, Medicine.)
Esquires.
Gentlemen.
Yeomen.
Tradesmen.
Artificers.
Labourers.

*N. B.* Married women and widows have the same rank among each other as their husbands would have among themselves, except such rank be merely professional or official. And unmarried women to the same rank as their eldest brothers would bear among men during the lives of their fathers."

Father Menestrier has expressed the principal rules of heraldry in a very few verses, which may easily be retained in the memory.

"Le Blazon composé de differens emaux
N'a que quatre couleurs, deux panes, deux metaux.
Et les marques d'honneur qui suivent la naissance
Distinguent la noblesse, et font sa recompense.
Or, argent, sable, azure, gueules, sinople, vair,
Hermine au naturel, et la couleur de chair,
Chef, pal, bande, sautoir, fasce, barre, et bordure,
Cheveron, pairle, orle, et croix de diverse figure,
Et plusieurs autres corps nous peignent la valeur
Sans metal sur metal, ni couleur sur couleur.
Support, cimier, bourlet, cri de guerre, et devise,
Colliers, manteaux, honneurs et marques de l'Eglise,
Sont de l'art du blazon les pompeux ornements;
Dont les corps sont tirés de tous les elements,
Les astres, les rochers, fruits, fleurs, arbres, et plantes,
Et tous les animaux en leur formes differentes,
Servent a distinguer les fiefs et les maisons,
Et de communautés composent les blazons.
—De leur termes precis enoncer les figures
Selon qu'ils auront de diverses postures.
Le *blazon plein* echoit en partage a l'aisné;
Tout cadet doit briser comme il est ordonné."

*Abrege, p. 62.*

# INDEX.

HERAT is a city of Persia, and formerly the capital of Khorassin. It is the ancient *Aria* or *Artacoana*, the capital of Ariana. Herat is situated in a spacious and highly cultivated plain, encircled by lofty mountains, and traversed by the river Herirood, which runs into the Caspian Sea near Zaweh. The city, which covers an area of four square miles, is surrounded with a lofty wall and a wet ditch, and is defended by a citadel in the western face, which is a small square castle, built upon a mound with burnt brick, and flanked with towers at the angles. On each face of the city is a gate, and two in the northern face, and from each gate a spacious and well supplied bazar leads to the centre of the town. The street which leads from the southern gate to the cattle-market, opposite to the citadel, is covered with a vaulted roof. Independent of the public fountains on either side of the Bazars, almost every house has a separate fountain of water. The principal public buildings are the residence of the prince, and the chief mosque. The former is a mean building, with a common gateway. In the front of the building is an open square, with the gallows in the centre. The mosque, which is called the Mesghed Jama, was formerly a magnificent building, and covered a space of eight hundred square yards. It is now, however, falling rapidly into decay.

Herat carries on a very extensive trade, and has therefore received the appellation of *Bunder* or *Port*. It is the emporium of the commerce carried on between Cabul, Cashmere, Bukhara, Hindostan, and Persia. Cabul supplies the inhabitants of Herat with shawls and raw sugar, chintz, muslin, leather, and Tartary skins, which they export to Meshed, Yezd, Kerman, Ispahan, and Tehraun, and receive in return dollars, tea, china-ware, broad cloth, copper, pepper, and sugar-candy. Kerman furnishes dates and shawls, and they receive carpets from Ghaen. The staple commodities of Herat, are silks, saffron, and assafœtida, which are exported to Hindostan. The gardens are filled with mulberry trees for the use of the silk worms, and the assafœtida is produced on the plains and hills near the city. The trade is principally carried on by the Hindoos, who alone possess capital and credit, and who are highly distinguished by the government, in consequence of their great commercial concerns.

The severity which sometimes characterises the winter at Herat, is often injurious to the crops; but nothing can surpass the fertility of the plain, which produces the most abundant crops of wheat, barley, and every kind of fruit known in Persia. The roses in the vicinity of the town are so plentiful, that it has obtained the name of *Sargultzar*, or the city of roses. The cattle are small, and by no means numerous, but the broad tailed sheep are abundant. The revenue of the town is estimated at 4½ lacks of rupees. It is raised by a tax on caravanseras, shops, and gardens, and a duty on exports and imports. The town is governed by Prince Hadjy Firooze, son of the late king of Cabul, who pays an annual tribute of 50,000 rupees to Persia. The population of Herat is 100,000, of whom 10,000 are Patans, 600 Hindoos, and the remainder Afghans, with a few Jews. East Long. 63° 14′, North Lat. 34° 12′. See Macdonald Kinneir's *Geographical Memoir of the Persian Empire*, p. 181—183.

HERAULT is the name of one of the departments of France, formed out of the dioceses of St Flour, Lodeve, Montpellier, Bezieres, and Agde in Lower Languedoc. It is bounded on the north by the departments of the Gard and the Aveyron, on the west by those of the Tarn and the Aude, on the south by that of the Aude and the sea, and on east by the Gard. Its principal rivers are the Herault and the Orbe; the Herault passes by Pezenas, and runs into the sea at Agde. The Orbe waters Bezieres. This department consists of hills, vallies, and plains of different soils. It produces all sorts of grain, wines, brandy, olives, chesnuts, fruits, silk, verdigris, and salt. The trade of the department is greatly facilitated by the canal of the South, which begins at Cette, passes within 12 myriameters of Montpellier, coasts along the Mediterranean, and after passing before Agde, it re-ascends to Bezieres and from this, after crossing the Orbe, it goes on to Narbonne. The woods in this department are very fine, but not numerous. They occupy only from 28 to 29 hectares, or from 54 to 55 acres, one half of which belongs to the nation. The contributions in 1803 were 334,317 francs. The principal towns are

| St Pons, | 4506 |

The population of the department is 291,957 See France.

HERCULANEUM, is an ancient city of Italy, situated on the Bay of Naples, and supposed to have been either founded by Hercules, or in honour of him, 1250 years before the Christian era. About 957 years later, the Romans seem to have taken possession of the city, and to have retained it ever after. In the year 63, it suffered severely from an earthquake, which, according to Seneca, occasioned the total ruin of part of it, and left the remainder in a tottering state. But in the year 79, an eruption of Vesuvius, for the first time exhibiting volcanic fires to the existing generation, buried the whole many feet deep, under repeated showers of stones and ashes; while other cities were overwhelmed by torrents of liquid lava, or swallowed up by the earthquakes which accompanied them.

*Cuncta jacent flammis et tristi mersa favilla.* Martial.

All memorials of the devoted cities were lost; and discussions on the places they had once occupied, were excited only by some obscure passages in the classical authors. Six successive eruptions contributed to lay them still deeper under the surface. But after sixteen centuries had elapsed, a peasant, in digging a well beside his cottage in 1711, obtained some fragments of coloured marble, which attracted attention. Regular excavations were made, under the superintendance of Stendardo, a Neapolitan architect; and a statue of Hercules, of Greek workmanship, and also a mutilated one of Cleopatra, were withdrawn from what proved to be a temple in the centre of the ancient Herculaneum.

Twenty or thirty years afterwards, the king of the two Sicilies, with a laudable love of science, directed a complete search to be made among the remains of the subterraneous city, and all the antiquities to be preserved. This was long and ardently prosecuted; and the entrance is now gained by a narrow passage, descending gradually to more than 70 feet from the surface, where it branches into numerous alleys leading to different streets and buildings. Neither the precise extent or population of Herculaneum can be ascertained, though it is probable that both were considerable; and we know that it was a city of the second order. All the streets run in straight lines; they are paved with blocks of lava, which indicates the vicinity of more ancient volcanic eruptions; and there is, for the most part, an elevated foot-path along their sides, for the convenience of pedestrians. The houses, whose exterior does not seem to have been ornamental or regular, consisted only of one story, built of brick. The walls of many are thrown out of the perpendicular, and some are covered with coloured stucco, upon which are executed paintings in fresco. From the general appearance exhibited by the different edifices, we may safely conjecture that the volcanic matter consisted of very fine dust, or ashes, which fell in repeated showers, and perhaps in a humid state, until the city was totally buried under it. Indeed it was so fine, that the most perfect impressions of the objects thus covered were imprinted there, and, on their being now removed, the cavity may serve for a plaster or metallic cast. By this means innumerable articles were preserved entire, and scarcely displaced from their original position, for the incumbent load received gradual accessions, unaccompanied by any extraordinary degree of heat or violence.

The remains of several public buildings have been discovered, which have possibly suffered from subsequent convulsions. Among these are two temples, one of them 150 feet by 60, in which was found a statue of Jupiter. A more extensive edifice stood opposite to these, forming a rectangle of 228 feet by 132, supposed to have been appropriated for the courts of justice. The arches of a portico surrounding it were supported by columns; within it was paved with marble; the walls were painted in fresco; and bronze statues stood between 42 columns under the roof.

Before the year 1738, the theatre was discovered; the size of which has afforded some conjectures regarding the population of Herculaneum. The building was nearly entire; very little had been displaced; and we see in it one of the best specimens extant of the architecture of the ancients. It seems to have had two principal gates, with inscriptions over the architraves of each, besides seven entrances, called *vomitoria*, communicating with the benches. Many columns and pilasters, with laboured entablatures, appeared in the *Proscenium*, and some supported bronze or marble statues. The walls were covered with paintings in the arabesque, and the floor paved with marble; that of the orchestra, consisting of the finest yellow antique, is preserved nearly entire; and similar decorations adorned the various apartments connected with the theatre. Twenty-five rows of high and wide marble benches accommodated the audience; which, rising gradually above each other, gave a full and distinct view of the arena below. The greatest diameter of the theatre, taken at the highest benches, is 234 feet; whence it has been computed, that it could contain 10,000 persons, which proves the great population of the city. This theatre was rich in antiquities, independent of that ornamental part to which we have already alluded. Statues, occupying niches, represented the muses; scenic masks were imitated on the entablatures; and inscriptions were engraven on different places. Analogous to the last were several large alphabetical Roman characters in bronze, and a number of smaller size, which had probably been connected in some conspicuous situation. A metallic car was found, with four bronze horses attached to it, nearly of the natural size; but all in such a state of decay, that only one, and the spokes of the wheels, also of metal, could be preserved. A beautiful white marble statue of Venus, only 18 inches high, in the same attitude as the famous Venus de Medicis, was recovered; and either here, or in the immediate vicinity, was found a colossal bronze statue of Vespasian, filled with lead, which twelve men were unable to move; besides many objects entire, there were numerous fragments of others, extremely interesting, which had been originally impaired, or were injured by attempts to obtain them. The Herculaneans are said to have had a particular taste for theatrical entertainments; and some authors have maintained, that, disregarding the danger which menaced them, they remained so intent on the performance, that both here, and at Pompeii, they were surprised by the eruption of Vesuvius, and buried under it. But we may reasonably conclude, that, with regard to Herculaneum, the theatre did not suffer materially from the earthquake, and that it was not attended with the destruction of the spectators. Remarkably few skeletons have been found in this city, though many occur in the streets of Pompeii; but one appears under the threshold of a door, with a bag of money in his hand, as if in the attitude of escaping, leaving its impression in the surrounding volcanic matter. Nevertheless, it might be here, as we are told of a different city, where the Emperor Nero, appearing on the stage, was surprised by a sudden earthquake; but the audience had time to escape, and the theatre fell without doing any injury. A similar incident occurred within these few years at Naples, where the decorations of the theatre were in visible motion before the terrified spectators, but the strength of its parts resisted the shock.

The exfodiation was prosecuted along the walls of the buildings, turning the corners, and entering by the doors and windows as they occurred. Two marble equestrian statues of the finest workmanship, which had been erected in honour of the two consuls, Balbi and son, were found opposite to the theatre: and in prosecuting the researches into the public edifices and private houses, or even through the streets, the workmen met with many things worthy of observation. A well, now containing good water, was seen surrounded by a parapet, and covered by an arch which had excluded the ashes. A capacious bath of a circular form was penetrated, and also repositories of the dead, still more ancient than the overthrow of Herculaneum. Fragments of columns of various coloured marble, beautiful mosaic pavements entire, and mutilated statues, were abundantly disseminated among the ruins. Some of the pavement, representing figures, has been taken up and again disposed in its original order, in a spacious museum prepared for the reception of the antiquities. The public edifices afforded a copious collection corresponding to their different uses; but many were utterly destroyed, such as the statues in the building containing forty-two columns. Numerous sacrificial implements, however, such as pateræ, tripods, cups, and vases, were recovered in excellent preservation, and even some of the knives with which the victims are conjectured to have been slaughtered. Numerous domestic utensils employed in the exercise of the arts, and contributing to the amusements of the existing generation, were all preserved.

When we reflect that 1600 years have elapsed since the destruction of this city, an interval which has been marked by numerous revolutions, both in the political and mental state of Europe, a high degree of interest must be experienced in contemplating the venerable remains of antiquity recovered from the subterraneous city of Herculaneum. Pliny the Younger, in his letters, brings the Romans, their occupations, manners, and customs, before us. He pictures in feeling terms the death of his uncle, who perished in the same eruption as the city we now describe: and that event is brought to our immediate notice by those very things which it was the means of preserving. Among these we see the various articles which administered to the necessities and the pleasures of the inhabitants, the emblems of their religious sentiments, and the very manners and customs of domestic life.

Articles in vast variety were obtained from the houses, wherein the beams appeared as if converted to charcoal; but it is to be observed, that all the remains of wood exhibit the same aspect to the very heart. They are not consumed or turned to ashes, owing probably to the exclusion of the external air by the showers of volcanic matter. It is singular, that while wood, which has remained during ages buried in the earth, or immersed in water, acquires additional consistence, this has entirely lost what it possessed. Pieces of thin and delicate texture have preserved their shape, but blocks of a large size are converted throughout to charcoal.

If the subjects recovered from Herculaneum be classed according to their value, the statues should be enumerated first, both as being of the finest workmanship and of the most difficult execution. Some are colossal, some of the natural size, and some in miniature; and the materials of their formation are either clay, marble, or bronze. They represent all different objects, divinities, heroes, or distinguished persons; and in the same substances, especially bronze, there are the figures of many animals. Sculpture, in its various branches, had attained a high degree of perfection among the ancients; their religious prejudices and manners greatly contributed to the perfection of the art; and we have ocular demonstration, that the reputation of their celebrated artists was not overrated. Paintings are interesting, but the small portion of the object represented, renders them far less so than statues which afford complete imitations, and are thence to be ranked as the most precious relics of antiquity. Here there are two statues seven feet high of Jupiter, and a woman in clay; and two of gladiators, in bronze, about to combat, are much admired. The same may be said of Nero in bronze, naked and armed as a Jupiter *tonans*, with a thunderbolt in his hand. A Venus *pudica* of white marble in miniature, is extremely beautiful, and also the statue of a female leaving the bath. In the year 1758, a fine bronze statue of a naked Mercury, supposed to have been the work of a Greek artist, was discovered: and in the course of the excavations extending beyond the confines of the city, a Silenus, with a tiger, sometimes his attribute, was found, which had formerly adorned a fountain. Several fauns or other sylvans, with vases on their shoulders, were obtained in the vicinity of Silenus, which are of bronze; and it is singular to observe, that the younger figures have silver eyes, a disagreeable deformity sometimes adopted in marble statues. The figure and attitude of a drunken faun, stretched on a lion's skin, and supported by one full of liquor, presents all that vacuity of thought and sensation of animal pleasure which accompany ebriety: another faun asleep, as large as life, presents a state of absolute repose. We have named two fine equestrian statues of full size. There is also a bronze equestrian statue of an armed Amazon, only sixteen inches high. There are many elegant statues of the goddesses and graces only eight or ten inches in height: and we likewise see some of the monstrous Egyptian divinities with which the Herculaneans were acquainted. Several fine busts or simple heads of the ancient philosophers, as Zeno, or Epicurus, stood in the houses; the name being inscribed below, or on a pedestal. Bas-reliefs likewise occurred, but few coins or medals. Gold coins of Augustus were found, and silver medallions, two or three inches in diameter, bearing uncertain devices.

The ancient pictures of Herculaneum are of the utmost interest, not only from the freshness and vividness of colour, but from the nature of the subjects they represent. All are executed in fresco; they are exclusively on the walls, and generally on a black or red ground. It has been supposed, from passages in the classics, that the ancients used only four colours, white, black, yellow, and red; but here are added blue and green.* Some are of animated beings, large as life, but the majority are in miniature. Every different subject of antiquity is depicted here: deities, human figures, animals, landscapes foreign and domestic, and a variety of grotesque beings. Sports and pastimes, theatrical performances, sacrifices, all enter the catalogue. Having occasion afterwards to speak cursorily of some of these subjects, we shall content ourselves with observing, that they are more remarkable for variety than for their intrinsic quality. One of larger size found in a temple, and the most celebrated, represents Theseus vanquishing the Minotaur, which lies stretched at his feet, with the head of a bull and the body of a man. A female, supposed to be Ariadne, and three children, form part of the group. This, along with a picture, composed of several figures as large as life, of which Flora is the most conspicuous, adorned a temple of Hercules; each is six or seven feet high and five broad. Another represents Chiron teaching Achilles the lyre; and female centaurs are seen suckling their young. The interior of a shoemaker's shop is exposed on a smaller scale; a feast, baskets of fruit, a grasshopper driving a parrot yoked to a car, a cupid guiding swans in the same manner, and many allegorical subjects are represented. It is impossible within these limited bounds to enumerate their varieties, but we shall immediately refer the reader to a specific work upon the subject, from which much entertainment will be derived. The king, desirous of preserving these pictures, directed them to be sawed out of the walls, a work of great labour and perseverance, after which they were put in shallow frames and kept in the museum.

It is said that a triremis or vessel, with three banks of oars, was discovered, with the iron or copper tackle and wood work complete, and that a drawing was taken of it; but the more material parts immediately fell to dust. A sea piece with vessels is among the paintings.

It is extraordinary, that numbers of perishable substances should have resisted the corrosions of time. Many almonds in the shell, imprinted with all the lines and furrows characterising their ligneous envelope, were dug out of the ruins of Herculaneum; figs and some kinds of wild apples were in preservation; and a sort of pine cone yet growing in the woods of Italy, the seeds of which are now ate, or used for culinary purposes. Grain, such as barley, and also beans and peas, remained entire, of a black colour, and offering resistance to pressure. The stones of peaches and apricots are common, thus denoting the frequency of two trees reputed indigenous in Armenia and Persia. But what is still more singular, a loaf, stamped with the baker's name in Roman characters, or the quality of the wheat, was taken from an oven, and was apparently converted to charcoal. Different parts of plants, prepared for pharmacy, were obtained from the dwellings of those who had been apothecaries. After such an amazing lapse of time, liquids have been found approaching to a fluid state —an instance of which cannot be sufficiently admired in a phial of oil conceived to be that of olives. It is white, greasy to the touch, and emits the smell of rancid oil. An earthen vase was found in the cellars containing wine, which now resembles a lump of porous dark violet coloured glass. We acknowledge, however, that there is great difficulty in comprehending how this change should have taken place. The ancients speak of very thick wines, requiring dilution previous to use, which would keep 200 years, and would then acquire the consistence of honey. Eggs are also said to have been found whole and empty. Solid pitch was found at the bottom of a vessel, wherein it had probably melted, as it afterwards did from heat in the museum at Portici, which stands near the entrance to the subterraneous city.

An entire set of kitchen furniture has been collected, which displays several utensils exactly similar to our own.

* See Sir Humphry Day's interesting paper on the colours used by the ancients, in the *Phil. Trans.* for 1815.—Ed.

The copper pans, instead of being tinned, are internally coated with silver, probably a better precaution, as more of the poisonous metals are expelled from the latter. These have not been attacked by verdigrease, whence the ancients perhaps understood some branches of metallurgy as well as the moderns. Here is a large brass cauldron, three feet in diameter, and fourteen inches deep, an urn or boiler for hot water similar to those on our tables, and also having a cylinder in the centre for a heater. There are pestles and mortars, and all kinds of implements for cutting out and figuring pastry; and, in short, a complete culinary apparatus. Utensils of finer quality were likewise collected, which had been employed at tables, as silver goblets, and vases, silver spoons, and the remnants of knives. But from the absence of forks, both among the other remains and in pictures, it is doubtful how far they were known to the ancients. It is probable, indeed, that their invention and common use are to be dated several centuries later.

Several articles belonging to personal ornament and decoration occurred: We shall not speak of the colours still in a condition fit for painting, because it is questioned whether they were such as it is known the ladies of that generation were accustomed to use for more ordinary purposes. Besides, they are red, blue, and yellow. Those with which females heightened their complexion were prepared both from minerals and vegetables, the latter being chiefly marine plants. Two silver bodkins, with which they pinned up their hair, eight inches in length, are preserved; the end of one appropriately sculptured with a Venus adjusting her tresses before a looking-glass held by Cupid. Gold armlets, bracelets, necklaces with pieces of plate gold suspended to them as a locket, are preserved. Small nets also with fine meshes, which some have supposed the ladies employed to tie up their hair; and others of coarser texture, which must have been used for other purposes. Pieces of cloth, coloured red on one side, and black on the other, were found on the breast of a skeleton; the texture of which, whether silk, woollen, linen, or cotton, antiquaries have not been able to decide. Very few jewels are discovered, which favours the idea of the inhabitants having had time to escape. There was a wooden comb, with teeth on both sides, closer on one of them than on the opposite; and portions of gold lace fabricated from the pure metal. Sandals of laced cords are seen, though it is more commonly believed that leatner was in general use among the Italians; and a folding parasol, absolutely similar to what we esteem a modern invention, was likewise discovered.

There is kept in the museum a case of surgeon's instruments, complete, with pincers, spatulæ, and probes; also a box supposed to have contained unguents; and pieces of marble, employed in braying pharmaceutical substances. A variety of carpenters' and masons' tools, as chissels, compasses, and trowels, were found, resembling our own; and bolts and nails, all of bronze.

The weights and measures of the ancients have excited considerable discussion, which those preserved in Herculaneum may elucidate: Different balances appear, of which the most common is analogous to the Roman steelyard: but those with flats for scales, though wanting the needle, are likewise seen. The weights are either of marble or metal, of all gradations up to thirty pounds; and from the marks exhibited by a set, well made of black marble, in a spherical shape, it is supposed the pound was divided into eight parts. A weight is inscribed *eme* on one side, and *habebis* on the other. There are pocket long measures, folding up like our common foot rule, which may throw some light on the length of the Roman foot. Neat copper vases are supposed to have been measures for grain; the capacity of one is 191 cubic inches.

The various implements for writing repeatedly occurred; and among the pictures is a female apparently listening to dictation. That the ancients were perfectly acquainted with the art of making glass is proved by the varieties discovered in these exfodiations. Considerable numbers of phials and bottles, chiefly of an elongated shape, are preserved; they are of unequal thickness, much heavier than glass of ordinary manufacture, and of a green colour. Vessels of cut white glass have been found, and also white plate glass, which antiquaries suppose was used in lining chambers, called *cameræ vitreæ*. Coloured glass, or artificial gems, engraved, frequently occur: and the paintings exhibit crystal vessels. We may remark in this place, that any one who studies the antiquities of Herculaneum, will find his researches greatly facilitated by frequent reference to the epigrams of Martial, whom nothing used in ordinary life seems to have escaped.

The beauty and variety of the vases have attracted particular notice, and they serve as excellent models for the moderns; for all the skill of the ancient artists seems to have been exhausted in their execution. There is one preserved four feet in diameter of fine white marble; others are of earthen-ware or silver, and the majority of bronze or copper. Some are low, wide, and flat; others tall and narrow, plain, fluted, or sculptured. Sacrificial vases were supported on tripods, whose construction seems to have been attended with equal care. Some of the latter are richly sculptured with real and imaginary figures of men and animals. One is ornamented with three lions heads, and is supported by as many paws: another rests on three Priapeian satyrs of elegant workmanship, or on the feet of eagles. The god of the gardens seems to have been treated with peculiar regard by the Herculaneans. He appears with all his attributes, of every possible variety, figure, and dimensions, in tripods, lamps, and household utensils. The articles on this subject are so common as to constitute a large branch of curious antiques, concerning the emblematic use of which we can only entertain conjectures. Several tripods are very ingeniously constructed, so that the feet may be closed or expanded by double sets of hinges. Endless diversity and infinite elegance are displayed in the lamps and candelabra, which are now affording models for the works of the moderns; but we do not know whether chandeliers have been discovered, at least they are so rare, that we may doubt whether the inhabitants often resorted to lights from wax or resinous substances. Sometimes a lamp appears as a shell, sometimes as a bird; then a human figure, or resembling a quadruped. The vases, lamps, and tripods, were particularly used in sacrifices, several of which are represented in the pictures; and among others, are sacrifices to the Egyptian deities. There were many funeral urns and sepulchral lamps, such as those regarding which vague ideas have been entertained as formed for containing perpetual fire.

In regard to sports and pastimes, numerous remains render us familiar with those of the ancients. Here we find dice, with the same disposal of points on a cube; and dice-boxes of bone or ivory, like those now used, besides some of a flattish shape. Several are false, being loaded on one side: and the manner of throwing the dice appears on a picture. No musical instruments were found but the sistrum, which we imperfectly understand, cymbals, and flutes of bone or ivory, are yet obtained. However, a concert is represented on a picture sixteen inches square, containing a lyrist, a player on a double flute, probably by a mouth piece, and a female apparently singing from a leaf of music; besides other two figures. Several theatrical masks, of different fashions, were found in clay and metal, along with moulds for their formation. Their use in dramatic representations, regarding which the reader may consult a work by *Ficoroni*, is well known, and is the subject of many of the pictures. The theatre, we repeat, was a favourite resort of the ancients; and some ivory tickets of admission, with the author's name, and that of the piece, are preserved from Herculaneum. Rope-dancing is exhibited on the pictures, wherein all the modern dexterity, of playing on musical instruments, pouring out liquids into cups, and other feats of address are shewn. The most elegant and graceful of the Herculaneum pictures are perhaps female dancers, suspended as it were among the clouds.

It is to be observed in general, with regard to the numerous articles relative to this brief detail, that the quality of the statutes infinitely surpasses that of the pictures; and that the vases, tripods, lamps, and candelabra, are frequently of the finest workmanship. Of many once complete, only fragments at this day remain; and while gold, silver, bronze, or clay, remain entire, iron has altogether wasted away.

After a vast collection of antiquities had been made, the king resolved on publishing a laborious and expensive work, containing engravings of those which appeared most curious. In the course of thirty-eight years, from 1754 to 1792, this was accomplished in nine folio volumes, including the pictures, bronzes, lamps, and candelabra: The first is devoted to a catalogue, five to pictures, two to the bronzes, and one to the *lucerne*. No less than 738 pictures are named in the catalogue, and the other articles are proportionally numerous. The work was, with royal munificence, presented to the principal public libraries in Europe; but owing to the succession of the king of the Sicilies to the crown of Spain, it is seldom to be seen complete. At the same time, it has been affirmed, that some of the engravings of the pictures appear with a perfection and delicacy which do not belong to the originals, although their general character be not lost.

In penetrating an apartment of a villa in the neighbourhood of Herculaneum, a number of supposed pieces of charcoal were carried off, which, by accidental fracture, exposed the remains of letters, and proved so many ancient manuscripts. Here Camillo Paderni, the keeper of the museum, buried himself during twelve days, and succeeded in carrying away 337 manuscripts; and, by subsequent careful research, the total number recovered now exceeds 1800. They were in various stages of decay; some so much disfigured and obliterated, that nothing could be determined regarding their nature from the beginning. However, the king instituted a society for investigating them completely. High expectations were formed by the European literati, of the knowledge which would be acquired respecting the history, the manners, and the customs of antiquity; more especially as the materials themselves indubitably remounted to a period of more than 1600 years. The manuscripts consisted of rolls, scarcely a span in length, and two or three inches in thickness, formed of pieces of Egyptian papyrus glued together. Some had a label in front, at one end of the roll, exposing the name of the work, or the author, as it occupied its place in the library. But the substance of the involutions was so crushed together, the ink or pigment employed for the character had faded to such a degree, that, united to the general injury which they had received from time, and the heat to which they had been exposed, the opening of them seemed at first sight to be impracticable. Accordingly, some snapped asunder like burnt wood, others flew into fragments, or they exposed nothing. The assistance of Piaggi, a monk, was obtained from the Vatican, who invented an ingenious method of unfolding the manuscripts without destruction, by means of a mechanical apparatus. The process was slow, but tolerably certain; and the first manuscript put on the machine, being unrolled in the year 1754, proved to be a treatise in Greek capitals, written by Philodemus, an Epicurean Philosopher, against music, with his name twice inscribed at the end, or interior of the roll. Similar means were adopted with other manuscripts, and they were partly successful. Almost the whole manuscripts are in Greek, very few having hitherto been found in Latin; and some of the rolls are forty or fifty feet in length. The entire surface of the roll is divided into successive columns, resembling our ordinary pages, each containing from forty to seventy lines in different manuscripts, this being dependent on the size of the roll; but each line is only about two inches long, and the column is no broader. In the original state, therefore, the reader held the roll before his eyes with one hand, while he unwound it with the other, as is represented by some of the Herculean pictures. Uncommon difficulties were experienced, from the decay of the substance, from frequent blanks and obliterations within, and from the absence of punctuation. Four volumes, all by Philodemus, were successively unrolled; and, in 1760, Piaggi reached a fifth by another author, on botany. But the king was induced to order it to be withdrawn, and a sixth volume was put on the machine, where it remained thirty-six years. After twenty years preparation, the work on music was published, with illustrations by Mazzocchi, a learned Italian, under the title *Herculanensium voluminum quæ supersunt*, *tomus* I. Napoli, 1793. It must have been anxiety for publication, not the desire of enlightening the world, that led to the selection of this volume, reputed a dull and controversial performance, which the most ingenious commentary is incapable of enlivening. Cicero, notwithstanding, has called the author *optimum et doctissimum;* Piso, the supposed owner of the manuscripts, derived his philosophy from him, and he was well skilled in the polite literature of the period. In the course of forty years from the discovery of the manuscripts, which were gradually withdrawn, only eighteen were unfolded. The accession of Charles, indeed, to the crown of Spain, and the death of Mazzocchi, had enervated the Herculanean Society, which was renewed in 1787 by the Marquis Caracioli, and the secretary of state thenceforward placed at its head. Yet the work advanced very tardily; few persons were employed, either from the difficulty, or want of interest in its prosecution; and it was perhaps totally interrupted by the political events which disturbed the peace of Europe. Mean time, six of the manuscripts were presented, along with other Herculaneum curiosities, to Bonaparte in 1802, by the sovereign of the Sicilies, in whose reign, indeed, we believe that both Philodemus and the volume of Lucerne were published; and ten volumes are said to have been sent, on some occasion, to the Prince of Wales.

At length a proposal was made on the part of this country, to co-operate with the Neapolitan government on a subject so important to the diffusion of literature as that of elucidating the Herculaneum manuscripts; and Mr Hayter, chaplain to the Prince of Wales, was appointed, with a regular commission to superintend their subsequent developement. A parliamentary grant of 1200*l.* was next obtained to aid its prosecution; and Mr Hayter, having commenced his operations under the most favourable auspices in 1802, employed thirteen persons in unrolling, deciphering, and transcribing. Some improvements seem to have been attempted in the evolution of the manuscripts by a chemical process; but of those subjected to it, we are told that "the greatest part of each mass flew under this trial into useless atoms; besides, not a character was to be discovered upon any single piece: the dreadful odour drove us all from the museum." Mr Hayter continued his operations from 1802 to 1806, during which time he affirms, that more than 200 papyri had been opened wholly or in part, and he calculated that the remainder would have been unrolled and copied within six years farther at latest. But as to the precise nature and description of these manuscripts, the accessions which literature has gained or would gain by the work, we are only informed that certain fac similes of some books of Epicurus were engraved.

It cannot but be considered particularly unfortunate that the public expectation, so repeatedly excited regarding what are to appearance among the most interesting memorials of antiquity, should be as often disappointed. Admitting every possible difficulty, and all the opposition which might have been experienced, unquestionably there were sufficient materials to make a specific report regarding the state and description of the manuscripts, towards the developement of which the public had so liberally contributed.

In 1806, during Mr Hayter's operations, it became necessary to evacuate Naples; but the existing government acquainted him, that the king had prohibited the removal of the manuscripts; and in the flight of the court, every thing was abandoned to the French, who seem to have continued the assistance in unrolling and deciphering as before. From the opposition which Mr Hayter experienced, he could do nothing more than retire with some of the fac similes to Palermo, where it appears he superintended engravings of them. Yet misunderstandings with the secretary of the state prevented him from procuring a complete copy of the whole, until the British ambassador interfered.

Ninety-four fac simile copies were then obtained, partly engraved it would seem, and partly in manuscript. These were carried to England by Mr Hayter on his final recall in 1809, and presented by the Prince Regent to the university of Oxford. However, a very confused and indistinct account of the whole of this matter has reached the public, which compels us to be thus brief regarding the history of the Herculaneum manuscripts.

Perhaps it may ultimately be found that they are less worthy of notice than was anticipated, particularly if we are entitled to form any judgment regarding the rest, from the inconsiderable portions that have already been published. See *Antichita d'Ercolano*, 9 vols. in folio; Bayardi *Prodomo delle Antichita d'Ercolano ;—Notizie. del Scoprimento dell' Antichita citta d'Ercolano ;* Venuti *Descrizione delle prime scoperte dell' Antichita citta d'Ercolano ;* Murr *de Papyris Herculanensibus ;* Drummond and Walpole *Herculanensia* ; Hayter, *Letter and Report on the Herculaneum Manuscripts ; Philosophical Transactions* for 1751, 1753, 1754, 1755, 1756 ; and Sir W. Hamilton *Campi Phlegræi*, p. 58. (*c*)

HERCULES, one of the most illustrious heroes of antiquity, and the first of the *Dii Minorum Gentium*, or demi-gods. He was descended from the kings of Argos; but in the Pagan mythology, he is said to have been the son of Jupiter by Alcmena, the wife of Amphitryon, king of Thebes. The period of his birth is uncertain; Herodotus places it about the year 1282, before the commencement of the Christian æra ; and in Blair's *Chronological Tables*, his death is placed in the year 1222 B. C.

The history of this celebrated personage consists of a tissue of prodigies. His first, or what may be called his infantine, exploits, were his strangling two serpents, which were sent to destroy him in his cradle ; and his killing a large lion, near his native city, Thebes. Next come those adventures, which are commonly known by the name of his twelve labours, undertaken by order of Eurystheus, and of a decree of the Delphian oracle, as it is said, by way of expiation for the crime of killing the three children which he had by his wife Megara, and in order to acquire immortality. The first of these was his combat and victory over the Cleonæan lion, in the forest of Nemæa ; the second, his conquest of the hydra, by which he is said to have cleared the fens of Lerna, near Argos, of the serpents that infested them, and which seemed to multiply as fast as they were destroyed ; the third, his destruction of the Erymanthian boar ; the fourth, his slaying the brazen-footed stag on Mount Menalus ; the fifth, his shooting the harpies, or stymphalides ; the sixth, his cleansing the stables of Augeas ; the seventh and eighth, his destroying the Cretan bull, and Diomede, the barbarous tyrant of Thrace, with his horses or mares who were fed on human flesh ; the ninth, his combat with Geryon, who is generally represented with three bodies ; the tenth, his conquest of the Amazons ; the eleventh, his dragging Cerberus up from the infernal regions ; and the last, his killing the serpent, or dragon, and carrying off the golden fruit from the garden of the Hesperides. The remainder of his exploits were those which he undertook voluntarily ; such as his slaying the giant Antæus, and Cacus, the notorious robber of Italy, fixing pillars in the *Tretum Gaditanum*, or Straits of Gibraltar, &c. It would appear, that this redoubted champion was by no means insensible to the influence of the tender passion, or proof against the allurements of vicious pleasure. The principal scene of his effeminacies was in Asia, whilst he lived with Omphale, queen of Lydia ; and he at length fell a sacrifice to the jealousy of his wife, Deganira, who, dreading the influence of his passion for Iole, the daughter of Eurytus, king of Æchalia, poisoned his robe, so that he died in great agonies on Mount Oëta. Ovid represents him as preparing his own funeral pile, and laying himself upon it with great composure.

Such is the substance of the traditional histories of this celebrated hero of antiquity, whose adventures have afforded ample materials to the sculptor and the poet. These traditions seem to contain a mixture of truth and fable. It appears from ancient authors, that there were several individuals of the name of Hercules, whose heroic actions were probably exaggerated, and ascribed to one man ; and to him, as his fame increased and spread abroad, was likewise transferred the credit of all great and valorous enterprises, the authors of which were unknown. Thus the Theban Hercules became, as it were, the representative of heroism and manly virtue, according to the notions of antiquity. Accordingly it has been observed, that none even of the twelve great pagan deities have so many monuments relating to them, as Hercules. The famous statue, called the Farnese Hercules, is well known. The hero is there represented as resting after the last of his twelve labours, leaning on his club, and holding in his hand the apples of the Hesperides. In this, and in all the other figures of him, he is formed by the breadth of his shoulders, the spaciousness of his chest, the largeness of his size, and the firmness of his muscles, to express prodigious strength, and a capacity of enduring great fatigue. His other attributes are, his lion's skin, his club and his bow. See Plate CCXXXIV. Fig. 2.

Hercules was peculiarly honoured among the Greeks, by the epithet of *Musagetes*, the conductor of the Muses ; and among the Romans, by that of *Hercules Musarum*. In reference to these titles, he is represented, on medals, with a lyre in his hand ; and the reverse is marked with the figures of the nine Muses, with their appropriate symbols. (*z*)

HEREFORD is a town of England, in the hundred of Grimsworth, 135½ miles W. N. W. from London. It is situated on the left bank of the river Wye, over which it has a stone bridge of six arches, constructed in the 15th century. The streets are in general wide: the inns are particularly good, one or two of them being equal to any in the kingdom. The public buildings particularly worthy of notice are, the cathedral, bishop's palace, college, county gaol, and theatre. The general plan of the cathedral is that of a cross. The interior is very interesting, though not nearly so much so as it was before the removal of the sepulchral memorials, painted glass, &c. The see of Hereford comprehends Herefordshire, and part of Shropshire. It is rated in the king's books at 768*l.*: its real value is supposed to be about 3000*l.* The civil government of the city is vested in a mayor, six aldermen, a common council consisting of 31 members, an high steward, and a recorder. It returns two members to Parliament, the right of election being vested in the citizens and freemen, to the number of about 1200. The situation of this city, on the banks of the Wye, would be extremely favourable to its trade, if the navigation of that river were less precarious. The principal manufacture carried on is gloves. Cyder, grain, and oak bark, are conveyed in considerable quantities down the river to Bristol and other places; and by means of the same navigation, the city is supplied with coals from the forest of Dean. This city suffered much during the wars between the houses of York and Lancaster, and also during the wars between Charles and his parliament. In 1803, its population was 6828; in 1811, it amounted to 7306. See Duncombe's *Agriculture of Hereford; Beauties of England and Wales*; vol. v.; and Marshall's *Rural Economy of Gloucestershire, &c.* vol. ii. p. 221, &c. (W. S.)

HEREFORDSHIRE is an inland county in the west of England, and on the borders of Wales. It is situated between 51° 53′ 7″, and 52° 29′ 43″ North Latitude, and 2° 28′ 30″ and 3° 19′ 32″ West Longitude from London. It is bounded on the north by Shropshire; on the west by the counties of Radnor and Brecon, from the latter of which it is separated by the Hatterel Hills, or Black Mountains; on the south by Monmouthshire and Gloucestershire, being separated from the former by the river Wye, and from the latter, partly by the river Munnow; and on the east it is bounded by Worcestershire. Its outline forms nearly a circle, but its circumference is made irregular by many windings and indentations. The extent, from Ludford on the north to the opposite border, near Monmouth on the south, is 38 miles; and from Clifford on the West, to Cradley on the east, 35 miles. Some detached parts are situated beyond the general outline; the parish of Farlow being wholly insulated by Shropshire—that of Rochford by Worcestershire; Lytton hill by Radnorshire; and a considerable tract of land, called the Futhog, by Monmouthshire. According to the original report to the Board of Agriculture, the gross number of acres is 781,440; but in Mr Duncombe's report they are stated to be only 600,000. In the returns to Parliament respecting the poor rates, they are stated at 621,440; while Mr Marshall estimates them so high as 800,000. On the supposition that there are 600,000 acres, which is the most probable, it is computed that 30,000 are the sites of towns, roads, water, &c. and 50,000 waste lands and woods; hence there are about 520,000 acres of cultivated ground; a much larger proportion than most of the other counties of England contain.

Herefordshire is divided into eleven hundreds, viz. Broxash, which contains 26 parishes; Ewias Lacey, which contains seven parishes; Greytree, which contains 17 parishes; Grimsworth, which contains 23 parishes; Huntingdon, which contains eight parishes; Radlow, which contains 24 parishes; Stretford, which contains 15 parishes; Webtree, which contains 27 parishes; Wigmore, which contains 14 parishes; Wolphey, which contains 24 parishes; and Wormelow, which contains 30 parishes; making in all 215 parishes, besides six parishes in the city of Hereford. Besides this city, which is also the county town, there are in Herefordshire two borough towns. Weobley and Leominster; and five other market-towns, Ross, Ledbury, Kington, Bromyard, and Pembridge. It returns eight members to parliament, viz. two for the county, two for the city, two for Leominster, and two for Weobley. It is in the province of Canterbury, and diocese of Hereford, and in the Oxford circuits.

The general aspect of this county is extremely beautiful; its surface is finely diversified, and broken by swelling heights in such a manner as to resemble the more central parts of Kent; no wide open vale, nor any extensive range of hills, appear in the north-western quarter; some separated links of the Welch mountains rise above the hillocks and minor hills, which are scattered over the rest of the county. In short, Herefordshire may be said, without exaggeration, to be altogether beautiful. From many of the elevations, the prospects are uncommonly fine; rather rich and luxuriant, however, than grand, or even picturesque. The forest prospects are from the Malvern hills on the east, and the Hatterel, or Black Mountains, on the west.

It is equally favoured in respect to soil, which is every where fertile; no watery bottoms, nor thin-soiled barren hills, except perhaps in the northern and western outskirts; every other part is uniformly productive. The eastern side of the county is mostly a stiff clay, of great strength and tenacity; for the most part red, but in some places of the ordinary colour. The western side is lighter, but still a productive soil. The county is clothed in almost perpetual verdure: on every side luxuriance of vegetation is exhibited, in widely extended corn fields, rich orchards, expansive meadows, and flourishing plantations. The subsoil, as well as the soil, contributes to this wonderful and almost unrivalled fertility. It is mostly limestone of different qualities. In some parts, particularly near Snodhill castle, it assumes the appearance and properties of marble, being beautifully variegated with red and white veins. Deep beds of gravel are occasionally met with in the vicinity of the city of Hereford, and the subsoil of several of the hills is of siliceous grit. Fullers earth is sometimes dug near Stoke; and red and yellow ochres, with tobacco pipe clay, are found in small quantities in various parts of the county. Iron ore has been met with on the borders of Gloucestershire, but none has been dug for many years.

The principal rivers in Herefordshire are, the Wye, the Lugg, the Munnow, the Arrow, the Frome, the Teme, and the Leddon. The Wye, so highly and deservedly celebrated for its picturesque beauties, enters Herefordshire near Clifford. Between Whitney and Hereford, its general character is mild and pleasing, consisting of delightful reaches, with the most agreeable landscapes and luxuriant scenery on both sides. From Hereford to Ross its features occasionally assume greater boldness; but, at the latter town, it resumes the brightness and rapidity of its primitive character, and forms the admired bending scen from the churchyard of Ross. Beneath the arches of Welton bridge it flows through a charming succession of meadows: the peninsula of Symond's rock succeeds, round which the river flows in a circuit of seven miles, though the opposite points of the isthmus are only a mile apart. New and pleasing objects now rapidly succeed one another; and the romantic village of Whitchurch, stupendous hills, and hanging rocks, exhibit a rare union of what is grand, beautiful, and picturesque. Shortly afterwards, the Wye quits the county and enters Monmouthshire. This river is navigable to Hereford in barges from 18 to 40 tons; but either a large or small supply of water is fatal to the navigation. The Lugg, which rises in Radnorshire, enters Herefordshire on the north-west side: near Stapleton castle, below Leominster, it is joined by the Arrow and the Frome. Soon after its junction with the latter, it falls into the Wye. The Munnow rises on the Herefordshire side of the Hatterel mountains; and, after many windings, forms the boundary between the county and Monmouthshire, till it quits the former. The Teme enters Herefordshire a short distance north-west from Brampton Bryan, but it soon enters Shropshire; thence again it enters Herefordshire, but soon leaves it for Worcestershire, where, having made a considerable circuit, it once more flows on the borders of this county, after which it falls into the Severn. The Leddon rises on the east side of Herefordshire, and after running south, and giving name to the town of Ledbury, it flows into Gloucestershire, and unites with the Severn. The Arrow enters Herefordshire from Radnorshire, and, flowing to the east, falls into the Lugg near Leominster.

The inland navigation of this county is very imperfect. The Hereford and Gloucester canal, which was begun in 1791, is not yet completed. It begins at Hereford, and is to fall into the Severn near Gloucester. Its total length is to be 35 miles 5 furlongs. At the beginning of it is a tunnel of 440 yards, and another about the middle of the summit 1320 yards long. The Kingston and Leominster canal begins at the former place, crosses the Lugg, and afterwards the Teme, and is to unite with the Severn near Stourport in Worcestershire. The total length is to be 45 miles: on it there are two tunnels, one of 1250, and the other of 3850 yards.

The greatest estates in this county belong to Guy's Hospital, the Duke of Norfolk, the Earls of Oxford and Essex, Sir George Comerall, R. P. Knight, Esq. &c. In that part of the hundred of Wormelow, called Irchenfield, the tenure of gaval-kind prevails, by which, in cases of persons dying intestate, landed property descends in equal divisions to all the sons. In the manor of Hampton-Bishop, which belongs to the see of Hereford, the tenure of borough-english prevails, by which the youngest son succeeds, to the exclusion of his brothers. Copyhold property is not so common in this as in many other counties of England. Leasehold estates are more common. They are for the most part held under the dean and chapter of Hereford, the corporation of that city, &c. It is estimated, that two-thirds of the whole county is freehold, and the remaining third under the other tenures. The size of farms varies from 200 to 400 acres.

The produce of Herefordshire is uncommonly various. In a general view, however, it may be regarded as a corn county. The bottoms, nevertheless, furnish great quantities of grass; and the sides of the hills produce in great abundance, and of excellent quality, most kinds of woods, especially oak. The immediate banks of the vallies, and the skirts of the higher hills, are covered with orchards. The objects of husbandry are, principally, cattle, sheep, swine, corn, hops, and fruit liquor; but two products render Herefordshire particularly famous, its cyder and its wool.

The principal cultivated lands are under tillage. The wheat grown in the vales, in the vicinity of Hereford, and thence through the clays towards Ledbury, is of a remarkably fine quality. The lighter lands produce excellent barley. Ross is the centre of the principal barley district. Oats are grown in most abundance on the borders of Wales, and on the eastern confines of the county. Neither turnips, nor artificial grasses, are sufficiently attended to.

The most fertile meadows lie on the banks of the Wye, Frome, and Lugg. For fattening cattle they cannot be exceeded; but Herefordshire has no pretensions to rank among the dairy counties. Mr Knight has proved by experiments, that equal quantities of milk in Herefordshire and Cheshire will produce unequal quantities of curd, highly to the advantage of the latter county.

Considerable quantities of hops are grown in this county, particularly about Bromyard, in that part of Herefordshire bordering on what may be called the hop district of Worcestershire. They are of two kinds, the white and the red; but the former are the most delicate, and are preferred by the buyers.

Plantations of fruit trees are found in every aspect, and on every soil; but the most approved site is that which is open to the south-east, and sheltered in other points, but particularly in the opposite direction. The period when the orchards of this county acquired the high character which they still retain, seems to have been the reign of Charles I. when, according to Evelyn in his *Pomona*, by the noble exertions of lord Scudamore of Holm Lacey, and other gentlemen, Herefordshire became in a manner " one entire orchard." Of the apples that are cultivated, there are various kinds, yielding liquors of different quality and strength. The Styre cyder is remarkable for a strength and body unusual to this liquor, and keeps very well. The pears most in estimation are the Squash, so called from the tenderness of its pulp; the sack pear, the red pear, and the Longland. Every pear tree, when nearly fully grown, will afford an annual average produce of 20 gallons of liquor. Many single trees in this county have produced a hogshead in one season; and an extraordinary tree growing on the glebe land in the parish of Holm Lacey, has more than once filled fifteen hogsheads in one year. In other respects, this is a most extraordinary tree; for its branches becoming long and heavy, their ends fell to the ground, where they took root, each branch becoming as it were a new tree, and in its turn producing others in the same way. Nearly half an acre of land is covered with this tree.

The produce of an acre planted with apple trees, will generally be found nearly one-third less than the produce of pear trees on the same space; but the former begin to bear at an earlier age. As an object of sight, the pear tree is far superior. The orchards are of various sizes, from 4 or 5 to 30 or 40 acres. The principal markets for the fruit liquors of Herefordshire, are London and Bristol. From the latter, great quantities are sent to Ireland, to the East and West Indies, and to foreign countries, in bottles. The principal part of the liquor is bought immediately from the press by the county dealers. They prefer it in that state, in order that the fermentation and subsequent management may take place under their own direction.

In the opinion of Mr Marshall, the Herefordshire breed of cattle, taking it all in all, may, without risk, be deemed the first breed of cattle in the island. Those of Devonshire and Sussex approach nearest to them in general appearance; but they are of a larger size, and an athletic form. The prevailing colour is reddish brown, with white faces. As beasts of draught, their form is nearly complete; and the females at least fat kindly at an early age. In Herefordshire, working oxen are the principal object of breeding. Half the plough teams are of oxen, and they are also used frequently in carriages. They are bred chiefly in the north-western quarter of the county; but more or less in every other quarter, except the Ryeland. The most valuable collection of cattle to be seen out of Smithfield, are often met with at the Hereford Michaelmas fair.

This county has long been celebrated for a peculiar breed of sheep, called the Ryeland breed, from an indeterminate district in the southern quarter of the county which goes by the name of Ryeland, on which this breed of sheep are principally reared. These sheep are remarkable for the sweetness of their mutton, but still more so for the fineness of their wool: they are a small white-faced, hornless breed, their form being extremely beautiful. In the management of the store flocks of this breed, what is provincially termed a *cot* is used: this is a building in which they are shut up during the night, instead of being folded in the open field. The Merino has been crossed with this breed to great advantage. Leominster is the principal wool market in the county, hence Leominster wool has long been famous.

The roads in Herefordshire, even so late as 1788, when Mr Marshall visited the county, were very bad, indeed proverbially bad; but since that time they have been much improved.

There are no manufactures of any extent or consequence in the county; for the manufactures of gloves and flannel in Hereford, and of cloth at Ledbury, are by no means so important as to deserve particular notice.

The returns made under the act of the 26 George III. report the nett expences for maintaining the poor throughout the county, in the year 1776, to have been 10,393*l*. The average of the years 1783, 1784, and 1785, as returned under the same authority, was stated at 16,727*l*. In the year 1805, Mr Duncombe estimated them at 20,000*l*. By a return made to the House of Commons in February 1806, containing an account of all money raised by poor's rates, or other rate or rates, in the several counties of England and Wales, in the year ending 25th of March, 1815, it appears that 243 parishes and places in Herefordshire paid, under these rates, the sum of 81,182*l*.: sixteen parishes or places had made no return.

The earliest inhabitants of this county, of whom we have any notice, were the Silures; after a long and strenuous opposition to the Romans, they were subdued in the 73d year of the Christian era. Under the heptarchy, Herefordshire formed part of the kingdom of Mercia, and was the last which submitted to the Saxon authority.

According to the act of 43 George III. for taking an account of the population of Great Britain, the number of inhabitants in the year 1801 amounted to 89,191. The following is the result of the population returns in 1811:

| | |
|---|---|
| Houses inhabited | 18,572 |
| Families inhabiting them | 20,081 |
| Houses building | 154 |
| Houses uninhabited | 724 |
| Families employed in agriculture | 12,599 |
| Ditto in trade | 5,044 |
| Ditto in other lines | 2,438 |
| Males | 46,404 |
| Females | 47,669 |
| Total inhabitants | 94,073 |

HERESY, (Lat. *Hæresis*, Gr. αἱρεσις, from αιρεω, *I chuse*,) signifies an error in some essential point of Christian faith, publicly avowed, and obstinately maintained; or, according to the legal definition, *Sententia rerum divinarum humano sensu excogitata, palam docta, et pertinaciter defensa*. Particular modes of belief or unbelief, therefore, which have no tendency to overturn Christianity itself, or to sap the foundations of morality, cannot be held as falling within the above definition. It is properly the obstinacy, and not the error, that is considered as constituting the character of heresy. When a man embraces any opinion, however erroneous, but is at the same time humble and ingenuous, ready and desirous of receiving farther light and instruction, and of giving its due weight to every argument that is urged against him, he is not guilty of heresy. *Errare possum, hæreticus esse nolo*, is a celebrated maxim of St Augustine.

Among the ancients, the word *heresy* appears to have had nothing of that odious signification, which has been attached to it by ecclesiastical writers in later times. It only signified a peculiar opinion, dogma, or sect, without conveying any reproach; being indifferently used, either of a party approved, or of one disapproved, by the writer. In this sense, they spoke of the heresy of the Stoics, of the Peripatetics, Epicureans, &c. meaning the sect, or peculiar system, of these philosophers. In the historical part of the New Testament, the word seems to bear very nearly the same signification, being employed indiscriminately to denote a sect or party, whether good or bad. Thus we read of the sect or heresy of the Sadducees, of the Pharisees, of the Nazarenes, &c. See *Acts* v. 17, ch. xv. 5. ch. xxiv. 5. ch. xxvi. 5. ch. xxviii. 22. In the two former of these passages, the term *heresy* seems to be adopted by the sacred historian merely for the sake of distinction, without the least appearance of any intention to convey either praise or blame. In *Acts* xxvi. 4, 5, Paul, in defending himself before king Agrippa, uses the same term, when it was manifestly his design to exalt the party to which he had belonged, and to give their system the preference over every other system of Judaism, both with regard to soundness of doctrine, and purity of morals.

It has been suggested, that the acceptation of the word αἱρεσις, in the Epistles, is different from what it has been observed to be in the historical books of the New Testament. In order to account for this difference, it may be observed that the word *sect* has always something relative in it; and therefore, although the general import of the term be the same, it will convey a favourable or an unfavourable idea, according to the particular relation which it bears in the application. When it is used along with the proper name, by way of distinguishing one party from another, it conveys neither praise nor reproach. If any thing reprehensible or commendable be meant, it is suggested, not by the word αἱρεσις itself, but by the words with which it stands connected in construction. Thus we may speak of a strict sect, or a lax sect; or of a good sect, or a bad sect. Again, the term may be applied to a party formed in a community, when considered in reference to the whole. If the community be of such a nature as not to admit of such a subdivision, without impairing and corrupting its constitution, a charge of splitting into sects, or forming parties, is equivalent to a charge of corruption in that which is most essential to the existence and welfare of the society. Hence arises the whole difference in the word, as it is used in the historical part of the New Testament, and in the Epistles of St Peter and St Paul; for these are the only apostles who employ it. In the history, the reference is always of the first kind; in the Epistles, it is always of the second. In these last, the apostles address themselves only to Christians, and either reprehend them for, or warn them against, forming sects among themselves, to the prejudice of charity, to the production of much mischief within their community, and of great scandal to the unconverted world without. In both applications, however, the radical import of the word is the same; and even in the latter, it has no necessary reference to doctrine, true or false.

During the early ages of Christianity, the term *heresy* gradually lost the innocence of its original meaning, and came to be applied, in a reproachful sense, to any corruption of what was considered as the orthodox creed, or even to any departure from the established rites and ceremonies of the church. In the present article, we do not intend to enter into a minute history of the various heresies, which have at different times disturbed the repose of the church, and given occasion to persecutions, which are revolting to the milder genius of modern times. All that we propose is, to give a short view of the progressive doctrines of the law upon this subject.

In our definition of the word *heresy*, we have marked the essential character of the offence, as it falls under the view of the law. In the law of England, however, it seems difficult to determine precisely what errors amount to heresy, and what do not. By our ancient constitution, this was left generally to the determination of the ecclesiastical judge, who, in this respect, had a most arbitrary latitude allowed him. For the general definition of an heretic given by Lyndewode, (*cap. de Hæreticis*,) extends to the slightest deviations from the doctrines of the holy church: *hæreticus est qui dubitat de fide Catholica, et qui negligit servare ea, quæ Romana ecclesia statuit, seu servare decreverat.* Or, as the statute, 2 Hen. IV. c. 15, expresses it in English; "Teachers of erroneous opinions, contrary to the faith and blessed determinations of the holy church." Very contrary this to the usage of the first general councils, which defined all heretical doctrines with the utmost precision and exactness. And the uncertainty of the crime, which ought to have alleviated the punishment, seems to have enhanced it in those days of blind zeal and pious cruelty. It is true, that the sanctimonious hypocrisy of the Canonists went at first no farther than to enjoin penance, excommunication, and ecclesiastical deprivation, for heresy; though afterwards they proceeded boldly to imprisonment by the ordinary, and confiscation of goods *in pios usus.* But, in the mean time, they had prevailed upon the weakness of bigotted princes, to render the civil power subservient to their purposes, by making heresy not only a temporal but even a capital offence; the Romish ecclesiastics determining, without appeal, whatever they pleased to be heresy, and shifting off to the secular arm the odium and drudgery of executions, with which they themselves were too tender and delicate to intermeddle. Nay, they even pretended to intercede and pray, on behalf of the convicted heretic, *ut citra mortis periculum sententia circa eum moderetur*; (*Decret.* l. 5. t. 40. c. 27.) well knowing, at the same time, that they were delivering the unhappy victim to certain death. Hence the capital punishments inflicted on the ancient Donatists and Manichæans, by the emperors Theodosius and Justinian, (*Cod.* l. 1. tit. 5.); hence also the constitution of the emperor Frederic, mentioned by Lyndewode, (*cap. de Hæreticis*,) adjudging all persons, without distinction, to be burnt with fire, who were convicted of heresy by the ecclesiastical judge. The same emperor, in another constitution, ordained, that if any temporal lord, when admonished by the church, should neglect to clear his territories of heretics within a year, it should be lawful for good Catholics to seize and occupy the lands, and utterly to exterminate the heretical possessors. And upon this foundation was built that arbitrary power, so long claimed, and so fatally exerted by the Pope, of disposing even of the kingdoms of refractory princes to more dutiful sons of the church, which formed a fruitful source of contention and animosity during the dark ages of Europe.

While Christianity was thus deformed by the demon of persecution upon the continent, it was not to be expected that our own island should be left entirely free from the same scourge. Accordingly, we find among our ancient precedents a writ *de hæretico comburendo*, which is thought by some to be as ancient as the common law itself. It appears from thence, however, that the conviction of heresy by the common law, was not in any petty ecclesiastical court, but before the archbishop himself in a provincial synod; and that the delinquent was delivered over to the king to do as he should please with him; so that the crown had a controul over the spiritual power, and might pardon the convict, by issuing no process against him; the writ *de hæretico comburendo* being not a writ of course, but issuing only by the special direction of the king in council.

But in the reign of Henry IV. when the eyes of the Christian world began to open, and the seeds of the Protestant religion (under the opprobrious name of Lollardy) took root in this kingdom, the clergy, availing themselves of the king's dubious title to demand an increase of their own power, obtained an act of parliament, (2 Hen. IV. c. 15.) which sharpened the edge of persecution to its utmost keenness. By that statute, the diocesan alone, without the intervention of a synod, might convict of heretical tenets; and unless the convict abjured his opinions, or if after abjuration he relapsed, the sheriff was bound *ex officio*, if required by the bishop, to commit the unhappy victim to the flames, without waiting for the consent of the crown. Another and subsequent statute (2 Hen. V. c. 7.) made Lollardy also a temporal offence, and indictable in the king's courts; which did not thereby gain an exclusive, but only a concurrent jurisdiction with the bishop's consistory. When the final reformation of religion began to advance, the power of the ecclesiastics became somewhat moderated; for although what heresy *is*, was not then precisely defined, yet we are told, in some points, what it *is not.* Thus the statute 25 Hen. VIII. c. 14. declares, that offences against the see of Rome are not heresy; and the ordinary is thereby restrained from proceeding in any case upon mere suspicion; that is, unless the party be accused by two credible witnesses, or an indictment of heresy be first previously found in the king's courts of common law. Yet the spirit of persecution was not then abated, but only diverted into a lay channel. For in six years afterwards, the bloody law of the Six Articles was introduced by the statute 31 Hen. VIII. c. 14. which established the six most contested points of Popery, viz. transubstantiation, communion in one kind, the celibacy of the clergy, monastic vows, the sacrifice of the mass, and auricular confession. These points, it seems, were "determined and resolved by the most godly study, pain and travail of his Majesty; for which his most humble and obedient subjects, the lords spiritual and temporal, and the commons, in parliament assembled, did not only render and give unto his highness their most high and hearty thanks," but did also enact and declare all oppugners of the first to be heretics, and to be burnt with fire; and of the five last to be felons, and to suffer death. The same statute established a new and mixed jurisdiction of clergy and laity, for the trial and conviction of heretics; the reigning monarch being then equally intent in destroying the supremacy of the bishops of Rome, and confirming all the other corruptions of the Christian religion.

Passing over the detail of the various repeals and revivals of these sanguinary laws in the two succeeding reigns, we shall proceed directly to the period of the final establishment of the Reformation in the reign of Queen Elizabeth. By statute 1 Eliz. c. 1. all former statutes relating to heresy are repealed, which leaves the jurisdiction of heresy as it stood at common law: viz. As to the infliction of common censures in the ecclesiastical courts; and, in case of burning the heretic, in the provincial synod only; or, according to Sir Matthew Hale, in the diocesan also. But, in either case, it is agreed, that the writ *de hæretico comburendo* was not demandable of common right, but grantable or otherwise merely at the king's discretion. 1. Hal. P. C. 405. The principal point, however, was now gained; for by this statute a boundary is, for the first time, set to what shall be accounted heresy, which is restricted, for the future, to such tenets only which have been heretofore so declared by the words of the canonical scriptures, or by one of the first four general councils, or by such other councils as have only used the words of the Holy Scriptures, or which shall hereafter be so declared by the parliament, with the assent of the clergy in convocation. For the writ *de hæretico comburendo* remained still in force; and there are instances of its being put in execution upon two Anabaptists in the seventeenth of Elizabeth, and upon two Arians in the ninth of James I. But this odious writ was at length totally abolished, and heresy again subjected only to ecclesiastical correction, *pro salute animæ*, by virtue of the statute 29 Car. II. c. 9. The matter, therefore, is now brought into its proper situation, with respect to the spiritual cognizance and spiritual punishment of heresy, unless, perhaps, that the crime itself ought to be more strictly defined, and no prosecution permitted, even in the ecclesiastical courts, until the tenets in question are, by proper authority, previously declared to be heretical. Under these restrictions, it seems necessary for the support of the national religion, that the officers of the church should have power to censure heretics, yet not to harass them with temporal penalties, much less to exterminate or destroy them.

The fury of persecution, indeed, has been greatly allayed, both by the prudence and the humanity of modern times; and the gradual repeal of the savage laws enacted against heretics, as well as the mitigation of cruelty in the legal punishments which were devised by barbarous ages, must be considered as a natural consequence of the advancement of civilization. With regard to one species of heresy, indeed, the legislature still thought it proper for a long while, that the authority of the civil magistrate should be interposed. For by the statute 9 and 10 W. III. c. 32. it was enacted, that if any person educated in the Christian religion, or professing the same, should by writing, printing, teaching, or advised speaking, deny the Christian religion to be true, or the Holy Scriptures to be of divine authority, or deny any one of the persons in the Holy Trinity to be God, or maintain that there are more gods than one, he should, upon the first conviction of professing his peculiar doctrines, be rendered incapable of enjoying any office or place of trust, civil or military, as well as ecclesiastical; and upon a second conviction, he should be disqualified from bringing any action, or from being guardian of any child, executor, legatee, or purchaser of lands, and besides suffer imprisonment for three years without bail. But if, within four months after the first conviction, the delinquent should, in open court, publicly renounce his error, he was to be discharged at once from all disabilities. But even this comparatively mild law could not well be executed in an enlightened age, and seemed to be retained merely *in terrorem*, until it was at length repealed in the year 1813. And it is the wish of many in this land of free inquiry, of knowledge, and liberal sentiment, that our statute books may be entirely rescued from the opprobrium of penal laws in the province of religion, and that the rights of conscience may be for ever confirmed, as not controlable by human laws, nor amenable to human tribunals. See Campbell's *Prelim. Dissert. to the Four Gospels, &c.*; Suicer's *Thes.* vol. i. p. 120, 124; Lardner's *Works*, vol. ix. p. 223, &c.; Blackstone's *Comment.* b. iv. ch. 4; Furneaux *Letters to Judge Blackstone*, p. 30; *Popular Reflections on the Progress of the Principles of Toleration*, &c. Newcastle, 1814; and *Edinburgh Review*, No. 51, p. 51, *et seq.* (z)

HERITIER, Charles Louis L' de Brutelle, an eminent French botanist, was born at Paris in 1746. In the year 1772, he was appointed Superintendant of the Waters and Forests of the Generalité of Paris; and, with the view of acquiring a knowledge of forest trees, he applied himself with diligence to the study of botany. The first work of L'Heritier was entitled *Stirpes Novæ.* The first fasciculus, with eleven finely engraved plates, appeared in 1784. It was completed in six fasciculi, containing in all eighty-four plates, with their descriptions, which were dated in 1784 and 1785, though they did not appear till some years afterwards. This circumstance gave rise to a controversy between the Abbe Cavanilles of Madrid and L'Heritier. In order to secure some of his own discoveries, L'Heritier published them in the form of monographs, with one or two plates. The subjects were *Louichea*, *Bucholzia Michauxia*, *Hymeno-pappus*, and *Virgilia*; and twelve of each only were printed.

After the Herbarium of Dombey had been put into the hands of L'Heritier in 1787, with orders to publish its contents, the influence of the court of Spain induced the French government to give orders that the Herbarium should be withdrawn; but L'Heritier having received notice of the measure, carried it over to London, where he remained for fifteen months, chiefly under the hospitable roof of Sir Joseph Banks. The state of his country, however, compelled him to return to Paris: and at this time the MSS. of his *Peruvian Flora* was complete, sixty drawings were finished, and many of the plates engraven. During his stay in England, he had collected the materials of his *Sertum Anglicum*, an unfinished work, of which he published several fasciculi, on the same plan as his *Stirpes Novæ*.

In the year 1775, L'Heritier married Madamoiselle Doré, who brought him five children, and died in the year 1794. In the year 1775, he became a *Conseiller à la cour des aides*, and was a long time the dean of that court. After the death of his wife, L'Heritier devoted himself to the education of his children; but his hopes were frustrated by the unprincipled conduct of his son. When he was one evening returning from a meeting of the National Institute, in August 1800, he was murdered, and his body was found next morning, with his money and other articles of value untouched. No discovery was ever made respecting this barbarous event; but suspicions of the most unnatural kind were confidently entertained. See Rees's *Cyclopedia*.

HERKEMER, a post town of Herkemer county, in New York, is situated on the north side of Mohawk river. The township includes the village called Little German Flats, and the celebrated plain called German Flats. The village contains a court-house, gaol, a Dutch church, and about 40 dwelling houses, which last are very indifferent buildings. It is 80 miles N. W. by W. of Albany, 16 S. E. of old Fort Schuyler, and 20 in a like direction from Whitestown. In the midst of the flats is a shrub oak plain of 80 or 100 acres, barren and stony, of no use but for building lots. It contained in 1796, 2073, and in 1800, 2554 inhabitants.

HERMANSTADT, Hermenstadt, or Szebeny, the *Cibinium* and *Hermanopolis* of the ancients, is a town of Hungary, and the capital of the province of Transylvania. It is situated in a champaign country, near the river Cibin, or Szeben, from which it derived the name of *Cibinium* and Szebeny. The principal public buildings are three monasteries for men, and one convent for women. One of the monasteries is for Ex-Jesuits, another for Catholics of the Franciscan order, and another for Greek monks of the order of St Basil. There is also a theatre, which is open during summer, a cassino, a public school for Protestants, and another for Greeks. In the great square there is a statue. The town is fortified with a double wall and deep moat. The museum of Baron Bruckenthal, a venerable nobleman, contains one of the finest collections in Europe of pictures, antiquities, and natural history. Dr Clarke has given a very minute description of it. The soap works of this town have been long celebrated; and the tallow candles manufactured here are so white, that there is a great demand for them at Vienna. The chateau of Freck, in the vicinity of the town, is worthy of being visited. The town was founded by Hermannus, a Greek emperor. It is well built, large, and populous, and contains from 15,000 to 16,000 inhabitants. The climate is said to be insalubrious. See Clarke's *Travels*, part ii. sect. iii. Supplement, p. 603, &c.; and *Hermannstadter Handlungs, gewerbs-und Reise-Kalender*, by M. Hochmeister, 1790.

HERMAPHRODITE, is a living being possessing the organs of generation belonging to both sexes.

On surveying the origin, the progress, and decay of the animal creation, there is sufficient reason to infer, that nature is infinitely more solicitous about preserving the different genera and species than the individuals of the race. Thus where their continuation is required by mutual concourse, as among the larger and more perfect creatures of the earth, it is necessary that the sexual organs of each should be reserved distinct and entire. Though accidental monstrosities ensue in other parts, the animal functions can be carried on, and sometimes with little injury; but imperfections in that portion of the frame appropriated for procreation, is for the most part an impediment to the laws which regulate the reproduction of living beings.

Nevertheless, the sexual organs, like other parts of animated matter, are liable to exhibit malformation, or monstrosities; and hence an idea has originated, that in man and different animals, the qualities of a perfect male and female may be united in the same individual. The fables of the ancients have perhaps conspired to give probability to these opinions. According to their allegories, a son of Mercury and Venus, who had been fostered by the Naiads of Ida, became enamoured of the nymph Salmacis, who fled from his embraces. But he joined her in a fountain where she could escape no longer, and besought the gods that their bodies might be united in one. His prayers were heard.

> "Vota suos habuere deos: nam mista duorum
> Corpora junguntur, faciesque inducitur illis
> Una . . . . . . . . . . . . . . . . . .
> Nec duo sunt et forma duplex nec femina dici
> Nec puer ut possint: neutrumque et utrumque videntur."
> Ovid *Metam.* lib. iv. cap. 9.

This androgynous being was thenceforth called Hermaphroditus, (whence the derivation of hermaphrodite,) and affords a subject for many beautiful sculptures from the hands of the ancients, which are still preserved.

No question has been more keenly agitated than the existence of human hermaphrodites; and the difficulty of the subject has been greatly increased, by that anxiety with which mankind conceal their nakedness; and, by an unjust abhorrence entertained against whatever seems beyond the standard of ordinary configuration. The Jews, for example, have a long catalogue of denunciations against persons labouring under disease or infirmity, natural or accidental; and even in the islands which we ourselves inhabit, monstrous productions of animals are almost invariably destroyed, as also those of mankind, where it can be effected with safety. But the vehemence of civil institutions seems to have been more conspicuously directed against those unfortunate beings known to labour under malformation of the sexual organs. At an early period of Roman history, a law was enacted, that every child of this description should be shut up in a chest and thrown into the sea; and Livy gives an instance where, on some difficulty with respect to the sex of an infant, it was directed to be thrown into the sea, *tanquam fœdum et turpe prodigium.* Nay, such a visitation seems to have been considered a mark of divine vengeance, for the execution was always followed by religious rites. The Jewish law is extremely solicitous regarding the disposal of hermaphrodites: the civil and canon law contain numerous hypotheses and enactments concerning them, and their succession is provided for by the laws of England.

The general scope of these laws tends to form regulations which shall apply according to the apparent predominance of sex; for the ancient legislators, though sufficiently aware of this distinction, do not seem to have admitted hermaphrodites as possessing a complete duplication of the generative organs. Being undoubtedly founded on experience, they cannot be considered void of interest. The numerous and diversified ordinances of the Talmud divide hermaphrodites into four classes; under which aspect they are to be treated partly as male, partly as female; next, as both male and female; and, lastly, as neither male nor female. First, they are like men, in being obliged to dress in male attire, and marry their brothers widows. Secondly, they are like women, because they may not converse with the male sex alone in private; they may walk among the dead; and are prohibited from bearing testimony: also, because they may shave their heads after a particular fashion, and pluck out their beards. Thirdly, they are to be esteemed both men and women, from having their share of the paternal and maternal inheritance, and such other succession, which they may claim as of either sex; they may retire to a sanctuary in case of accidental slaughter, and remain there as if it had been of either a man or woman; and if it be murder, they shall be put to death as for killing either a man or woman. Fourthly, hermaphrodites are to be considered neither man nor woman, by the law of Moses, in striking or calumniating another, but the judge shall ordain reparation; nor in making vows to the Deity, or in withdrawing from the world to devote themselves to his service. Many other partitions are made under these divisions. The canon and civil law displays all that uncertainty which is the natural offspring of prejudice, and the want of knowledge. Doubts and questions are started, useless to society, and oppressive to those affected by them; and in general they are, as in the Jewish law, to be solved according to the predominance of sex. Notwithstanding the numerous and absurd restraints put upon supposed hermaphrodites, it does not appear that they are precluded from marrying; on the contrary, if the two sexes in themselves be equal, a choice of the object is left, while other cases of marriage are regulated by sexual predominance. However, should the question be regarding an oath, the ordinances of the church seem to declare, that under the same equality of organization the testimony must be rejected. Hermaphrodites may not be promoted to holy orders, on account of deformity or monstrosity; nor can they be appointed judges, "because they are ranked among infamous persons, to whom the gates of dignity should not be opened." These are but a few of the prohibitions levelled against them. Many are cruel and unnecessary; and of so singular a kind, that a learned and humane physician exclaims, "would not any one conceive, that these supposed androgyni, instead of being of the same nature with us, however marked and deformed their parts of generation might be, were rather another race of animals, *sui generis*, than what they really are, when a string of laws compiled with so much accuracy, and in such a formal manner, has been exhibited and increased in all ages?" Yet rational enactments, founded on experience, are by no means void of utility; for observance of the law may prevent contention in all the mazes of doubt. Thus M. Ferrein, a modern physician, acquaints us, that he was consulted by the relatives of a young nobleman, labouring under a dubious conformation, who, if a male, as was commonly believed by them, would inherit a considerable estate, to which he could have no right if belonging to the other sex. Having afterwards occasion to illustrate the case, we shall not here anticipate the result. The subject of succession is doubtless fit for regulation, and consequently must frequently be determined by the predominance of sex. Happily the absurd penal laws, directed against this portion of our fellow creatures, are obsolete among us.

We shall now proceed to the opinions of recent philosophers and naturalists, which afford more copious sources of knowledge and entertainment. These are widely different from what were received of old, and most of the moderns incline to a different opinion: they doubt whether there is any well authenticated instance of a person having been seen with the organs of both sexes complete.

The origin of sex is in itself a dark and mysterious subject. That of no living animal can be distinctly recognised at an early period of existence; and some naturalists affirm, that there is reason to believe that the organization is such as to admit the evolution of the parts of the embryo, distinguishing either male or female; and that this evolution takes place during some period of gestation. Thus Ackermann adopts the principle, that *in omni individuo latent utriusque sexus genitalia, a modo dictis dependet circumstantiis an hæc an illa evolvi et increscere debeant.* The cause of evolution, however, if we rightly understand the author, will scarcely be admitted by naturalists; for he seems to ascribe it to matter of which the presence can only be presumed; *Discrimen quod a sexu est non absolutum sed ad ceteras partes respectivum dici debet. Sicut fœtus vel ex materiei plasticæ excessu vel ex oxygenii abundantia, coaluit, et prout in prima uterinæ vita epocha in fœtus incrementum vires agunt extraneæ, ita jam vir jam femina nascitur.* Sir Everard Home also appears to consider "the ovum, previous to impregnation, to have no distinction of sex, but to be so formed as to be equally fitted to become a male or female fœtus." On descending to the insect tribes, we find an intermediate kind between the two sexes, in those called neuters, incapable of generation. But certain naturalists have shewn, by ingenious experiments, that among bees, where this distinction is most prominent, the imperfection may be removed by a particular sort of food early supplied, and the sexual organs of females amply unfolded.

Leaving the subject of proper hermaphrodites, or those with the combined sexual organs entire, and capable of performing the generative functions, we shall now give some account of the three classes into which hermaphrodites may be divided. First, individuals exhibiting a mixture of the sexual organs, neither being complete; secondly, men labouring under a malformation of the parts; and, thirdly, females with analogous imperfections, by enlargement or defect. Examples of the first are extremely rare. Such perhaps is a case mentioned in Dr Baillie's *Morbid Anatomy*, where the person was 24 years of age, and examined as a patient of Nottingham hospital; and such perhaps was an androgynous child, which is the subject of discussion by Ackermann. Another instance is related in the *Journal de Medicine*, of a person who was long considered a woman, treated as such in society, and who was either married or lived in concubinage with a man. At the same time, others may consider all these as more strictly belonging to the class of males with malformation. The androgynous child of which we speak was born at Mentz in June 1803. Its singularity of structure was supposed indicative of the masculine gender by those present, and it was baptised as such. Having died at the age of five or six weeks, Ackermann, who had previously inspected the external configuration, obtained an opportunity of dissection, though the organs had declined along with the decay of the body during sickness. He found an intermixture of the sexual distinctions, removing the infant from a perfect male or female; the glans imperforate, scrotal labia, an uterine sac, and other doubtful indications, of which he has given an ample detail, illustrated by engravings; and at the same time he expresses his conviction of the androgynous nature of the subject.

A remarkable case came under the notice of some of the most learned continental physicians in the preceding century, respecting Michel Ann Drouart, a native of Paris, born about the year 1734. This individual was baptized, treated, and dressed as a girl, but having attained the age of 16, a report was circulated of her being a hermaphrodite, which led to a minute inspection by M. Moraud, who has presented us both with the result in detail, and several engravings. He found the external configuration partly masculine, partly feminine, but the former predominated. It corresponded to the age of the person, whereas the female characteristics belonged to a period of childhood, or early adolescence. An organ denoting virility appeared, but the urethra was absent; neither could he determine the exact point of a deep fissure, occupying the scite of the scrotum, into which the urine was discharged; and other medical men were equally unsuccessful. The breast was quite flat, and it always remained so; the person had the gesture, step, and voice of a youth, some rudiments of a beard on the upper lip, and a decided propensity for females. Yet, "says M. Moraud," there was a strange intermixture of the sexes in all respects; for the bason was more enlarged; and in comparing the two thighs together, one resembled that of a male, and the other that of a female." From these and concomitant circumstances, he formed an opinion that the subject was a male. Michel having left Paris some time after, underwent another inspection by M. Cruger, principal surgeon to the King of Denmark, who was induced, on the other hand, to consider the female character predominant; but he concludes, on the whole, that in strict definition the subject was neither male nor female. At the age of 21, some Genevese physicians had an opportunity of making their observations. The principal organ now exceeded the ordinary human dimensions in every respect; a thin black beard, nearly such as a young man of that age should have, appeared; and the breast and stature were completely those of the same sex. But now the propensities for males were supplanted by those formerly entertained; for at the age of 17, those evacuations characterising females of the human species had commenced, but experienced many irregularities and interruptions; and in 1761, had ceased for nearly three quarters of a year. Cotemporary observers were then inclined to depart from M. Moraud's sentiments, and to believe that there was a predominance of the female sex. However, some of the most recent authors, and those who have studied the subject most profoundly, seem to rank Michel Ann Drouart with hermaphrodites, exhibiting an intermixture of the sexual organs. M. Ferrein found the appearances in the more youthful subject above alluded to, completely the same as in the preceding individual in the essential parts. The whole external mien, intimately resembled that of girls at twelve years of age; the breast was quite flat, and the voice rather masculine. The external sexual organ, which would have indicated a male, was much smaller, though of the same structure as before; those of the female were somewhat misplaced, but the position of the urethra could be easily ascertained. Enough was disclosed, to induce M. Ferrein to declare, that this young nobleman was in fact a female, and would consequently be deprived of the expected inheritance. If his opinion be correct, the present case should be removed to the third class of persons designed hermaphrodites, though, from the doubts of the learned respecting the former, we are induced still to retain it here. It is not the structure of the sexual parts which is alone to be taken into view, but the total organization combined. The personal configuration, the habit of the body, the presence of a beard, the quality of the voice, propensities and dispositions, and other characteristics, added to any uncommon structure of these parts, shew that some of the male and female properties are confounded together. At an early period of gestation, human females are frequently mistaken for males; and hence an erroneous opinion has prevailed, of abortions at certain stages being more commonly of males. Many such fœtuses have been exhibited by Dr Parsons and others in illustration of the fact: and M. Ferrein concludes his observations on the preceding case with words of the following purport: "If to constitute a hermaphrodites wherein the sexes are combined, it is necessary to have the distinctive character of the male united to the female parts, there never was any woman who has not been a male during several months of her existence. In the earlier stages of pregnancy, that distinctive organ is prominent, and fashioned very nearly after the manner of males, so that those unskilful in anatomy, may suppose the embryo a male, though truly a female; nor on narrow inspection is the difference easily ascertained." The possibility of a complete duplication of the male and female organs is questioned, from there being no place in the human body which they could occupy, or wherein they could be contained. The same difficulty does not occur to us, and perhaps it can only be admitted where all the other parts, independent of them, are meant to be exactly of the natural structure and proportions. If so intimate a resemblance prevails in the sexual parts of the male and female embryo, something of an intermediate kind may be produced, should the position and developement of either be deranged; and thus exhibit an intermixture of sex; or, as we have some times witnessed, a complete duplication of some essential organ, as the head, hands, or feet, the like may happen to other parts. Among animals, very extraordinary instances have occurred of some decidedly males, to external appearance, nevertheless possessing female properties, such as the power of secreting milk. This faculty, indeed, is said in rare examples to reside in the nipples on the breast of men, the use of which is yet unknown by anatomists. A bull, which is reported to have generated five calves, had a small udder and small teats, which afforded a quantity of milk that on one occasion is said to have amounted to an English pint. In the *Philosophical Transactions* also, there is preserved an account of two wedders giving suck to lambs. Yet we cannot be too scrupulous in admitting such wonderful deviations from the course of nature. At the same time it must be recollected, that the rudiments of the mammæ exist in all the males of mankind and quadrupeds; and that before the age of puberty in the former, and when the the powers of procreation cease, there is a more intimate resemblance between the sexes than at other periods. Nor is it to be omitted, that emasculation produces a decided approximation to the feminine character. But, in prosecuting the intermixture of sexes in animals, an example is generally given in the free martin, on which the late celebrated Mr John Hunter observes—"When a cow brings forth two calves, and one of them a bull calf and the other to appearance a cow, the cow calf is unfit for propagation, but the bull calf becomes a very proper bull. This cow calf is called in this country a *free martin.*" Mr Hunter, on dissection, found such an intermixture of organization, that the animal always partakes of the nature of both sexes, though that of the one is sometimes more predominant than that of the other. Its external aspect is also different from the appearance of each, and it never betrays any sexual propensities. The muscular texture and the voice are peculiar, and the size is considerably larger than that of either bull or cow. Apparently there is much analogy between the free martin and an emasculated animal. Mr Hunter observes, that he has frequently seen hermaphrodite horses; that he dissected a hermaphrodite ass; and that sheep of this description are also to be found. The dissection of a hermaphrodite dog is given by Sir Everard Home in the *Philosophical Transactions* for 1799, where there was only one characteristic of the female decidedly present. However, there appear several reasons to conclude, that some of the animals quoted as undoubted hermaphrodites, ought rather to be classed with females labouring under vicious conformation. The intermixture of the masculine organs is not sufficiently prominent.

It has been observed, that among wild pheasants, a hen sometimes appears with the feathers of a cock; yet, on dissection, the female organs are found complete. Mr Hunter conceives, that this is a change which ensues at a certain age, and subsequent to the cessation of the procreative faculties; and he traces the history of three, where the alteration took place. But on descending still lower among the animal tribes, we find a multitude of beings apparently possessing the absolute character of hermaphrodism. Many of the mollusca contain individually the perfect organs belonging to either sex, not by accidental admixture or malformation, but by regular, natural arrangement. A sexual union takes place; all impregnate, and are impregnated; and this ensues by a singular and interesting distribution of the parts. Such is the case with many of the mollusca, or soft bodied animals with external organs, and those in general included under the order Helminthology. There can be no generation, however, without their mutual concourse; but in the animalcula infusoria, some seem perfect hermaphrodites, in so far as they propagate in an isolated state, while in others the sexual union seems requisite. In the numerous genus of polypi, the young animal protrudes from the side of the mother, and in its turn becomes a parent in the same way, while no union with another sex follows; or, as in the actinia, the young are formed within, and then discharged by the mouth. The subject of hermaphrodism may be still farther illustrated by a series of experiments which have recently been made on an extraordinary race of animals, bearing some analogy to the leech and snail, called *planariæ*. In one species, the sexual union takes place, and the result is eggs including young. In another, this union is never observed, but a portion of the tail separates by spontaneous division. It remains a shapeless mass, and absolutely quiescent, until the evolution of wanting organs enables it to perform all the functions of the parent. Having remained a certain time complete, this new animal loses a fragment of the tail, to become another perfect being; and thus their race is carried on. These creatures, therefore, seem to possess such structure as to enable each individual to reproduce its like.

Instances of mixed organs are of very rare occurrence in the human race. The most uncommon kind of configurations, indeed, are those which pass by the name of hermaphrodism. The older authors, nevertheless, on finding any monstrosities or imperfections in the sexual parts, immediately pronounced the individual a hermaphrodite; but as they were constantly in search of the marvellous, we must repose the less confidence in their observations. Nay, the moderns have, in some cases, too hastily bestowed this character; and we are told of an instance where, "the fore parts of the unhappy object were entirely wanting; even the bladder was not entire. It had the appearance as if the external parts of generation, and the anterior part of the bladder, had been cut off. Yet this unhappy object was vulgarly called a hermaphrodite."

The malformations of men are more frequently seen, and constitute the second class of hermaphrodites. Mr Brand relates, that being consulted in 1779, on occasion of some complaint in the groin of a child seven years of age, he found a vicious structure of the sexual organs, consisting of the unnatural presence of an integument confining the parts. This child had been baptized and brought up as a girl; but it was evident to him erroneously, for the male organs were present. By a slight incision of the integument, he liberated the restricted parts, and proved, to the great admiration of the parents, that they had mistaken a boy for a girl. The operator narrates these facts in a pamphlet, accompanied by three engravings, as large as life, of the appearances before and after the operation. Wrisberg, a German anatomist, in discussing a case of malformation, quotes an instance of a child probably labouring under a similar restriction. The parents, who were Jews, entertained so much doubt regarding the sex of their offspring, that they had deferred the accustomed rite of circumcision, until it should be determined whether it was actually a boy or a girl. But it died at the age of eight months. The same author mentions, that he removed a lesser restriction in a young man; and speaks of another person aged 46, reputed a hermaphrodite, who would not consent to undergo an operation, which, perhaps, would easily have determined his sex. His wife, to whom he had been married five years, then obtained a divorce against him, on account of impotency. An example of a mistake in sex, under more doubtful circumstances, is given by Abraham Kauu Boerhaave, a member of the Petersburgh Academy of Sciences. The child of a trumpeter was baptized Charlotte, and for some time brought up and treated as a girl. But the parents afterwards entertained some doubts regarding its real sex, and at the age of seven resorted to skilful persons to establish the truth. Instead of being a girl, as had been supposed, it was declared to be a boy. Sex, however, is much more doubtful, though the predominance of organization indicates the male, where the scrotum is absent, with a fissure in the perinæum, or a misdirection of the urethra. In the Transactions of the Academy of Siena, a person, named Augustine Broli, is described as being reputed a hermaphrodite, and having so little of the male configuration, that he doubted whether he ought to marry. On consulting Dr Caluri, however, he was assured he might do so with safety. If the description be correct, procreation was impossible. Persons have been mistakenly educated and employed as of a sex to which they did not belong. This was the case with a young man, who was brought up and dressed as a woman, yet, after he died, he was found to be essentially a man. Caspar Bauhin, likewise, speaks of a servant hired by a peasant, who being viewed with remarkable favour by his wife, led to an unexpected discovery of sex, under a malformation. An instance of doubtful sex, though more probably referrible to the third class, is quoted by Ackermann, in the case of Dorothea Derrier. Here opposite opinions were entertained by three medical men, Hufeland, Mursinna, and Stark, from the sexual formation conjoined with the general character of the whole body. The malformation of the male seems to be much more uncommon in animals, or perhaps it has attracted less attention.

But the third class, into which beings with a preternatural sexual structure may be divided, namely, females with malformations, is the most comprehensive of the whole. Nay, there are reputable authors who include all the rest under it, maintaining, that among the human race especially, the issue of every questionable case is, proving the subject a woman. Many examples are collected by Dr Parsons, to whose *Mechanical and Critical Enquiry into the Nature of Hermaphrodites*, we shall refer for the detail. The females of this class are sometimes designed the *macroclitorideæ*, from the preternatural enlargement they exhibit, and which is frequently such as to assume the appearance of virility, even in an adult. In the warmer climates, this being more usual, though probably not to a great extent, but attended with other circumstances, the operation of excision, concerning which the reader may consult the eastern travellers Niebuhr, Bruce, and Browne, is resorted to. Yet this malformation generally has other concomitants, either in corresponding restrictions in the rest of the sexual organization, flatness of the breast, woolliness on the chin, or a hoarser voice than belongs to females. De Graaf, a celebrated anatomist, mentions a female child which, from a preternatural enlargement, had been taken for a male, and baptised as such. It died, and he, along with several physicians and surgeons, having obtained an opportunity of dissecting the body, first had a drawing made of the external appearance; and then proceeding to a more strict examination, pronounced the organs those of a female only. An account has been given of a hermaphrodite in France, which merits particular attention, either in establishing the fact of hermaphrodism, or in illustrating how the learned may be deceived. Towards the year 1686, a maid-servant named Margaret Mauluse, born near Tolouse, was brought to the hospital of that city. She was about 21 years of age, with a feminine mien and appearance, a handsome face and agreeable expression, her bosom well formed, but she presented the male sexual organization, intermixed with the female structure. The evacuations peculiar to the sex were regular and abundant, as was testified by the attending physician; and, according to what he understood, the secretions denoting virility were proportionally copious. These facts being known to several physicians, the vicars general were consulted on the subject, and the result was, to compel the hermaphrodite to adopt the apparel of a man, under the name of Arnaud Mauluse, and to learn some profession. We are further told, that those concerned had no difficulty on the point, because "the hermaphrodite was sufficiently capable of the functions of a man, but of none belonging to a woman." Notwithstanding the necessity of compliance, however, this individual seems to have been dissatisfied with such a compulsory change of sex; and not finding it congenial to her nature, she afterwards solicited the king's permission to resume female attire. Some persons have supposed, that she merely exhibited a *prolapsus uteri* of an unusual form. Even within these few years, a woman was shewn as a hermaphrodite in London, pretending to the capacities of a male, who suffered under the same disease. The deception was detected, but not until a large sum had been realised by her, when she changed her abode. However, the enlargement exciting the idea of the presence of virility, is beyond dispute in adult females. Realdus Columbus says, a gipsey, whom he conceived to be a hermaphrodite, requested him to perform an amputation of the superfluous organization, which he declined from apprehensions of danger. Between 1730 and 1740, an African slave being brought from Angola to Bristol, and carried from thence to London, was exhibited as a hermaphrodite. She was about 26 years of age, presented nothing masculine in voice or appearance, but exhibited the like enlargement as before, attended with some other slight malformations. Dr Douglas made drawings of the whole; and Mr Parsons, having also seen the individual, concluded that she was absolutely a female. In the year 1750, a French woman, aged 18 years, was shewn also in London as a hermaphrodite, with what was called, "an inordinate enlargement" of the organ, and corresponding restrictions of a preternatural appearance. Sir Everard Home speaks of a Mandingo woman, carried from Africa to the East Indies, with flat breasts, a rough voice, and masculine countenance; who exhibited, besides, all the appearance of virility in enlargement, while the rest of the sexual organization seemed in the natural state.

It is exceedingly probable that almost the whole animals vulgarly esteemed hermaphrodites are of this class, females with malformations; because, whatever uncertainties prevail, there is always a decided predominance of the latter sex, though the masculine nature be very obscure. From these and similar uncertainties, a change of sex is said to have sometimes ensued in mankind. Nor is it improbable that this was firmly credited, since a diseased female may, to cursory inspection, manifest the semblance of virility. This imaginary change is most usually of women into men, and rarely of men into women. However Caspar Bauhin relates, that a child was baptised as a boy, became a soldier, and married a woman, with whom he lived seven years. But the supposed husband himself becoming pregnant, was most unexpectedly delivered of a daughter; and upon an investigation by the magistrates of the place of his residence, it appeared there was a malformation, never disclosed by the wife, and that the husband had on some occasion cohabited with a Spaniard. Thus the person supposed to be a male, proved in fact to be a female. Another instance, which seems to have been first related by Dr Douglas, an eminent anatomist, happened in London, where one of two waiters living in a tavern in like manner became pregnant by the other, to the great astonishment of the neighbourhood, at the reputed change of sex; and her dress was thenceforward changed to that of a female. The examples above given, shew that it is possible to mistake the sex of an infant from preternatural organization, but that the real nature of the individuals may be disclosed with the evolution, if we may so call it, of the sexual propensities.

The masculine and feminine character is deeply influenced by the state and condition of those organs which nature has appropriated for the perpetuation of the species. Thus the analogy between the sexes, hardly separable in the embryo, is infinitely greater during childhood, before the complete developement of the generative faculties, and after the procreative powers have ceased, than in the intermediate period. A corresponding analogy is produced by the destruction of the essential parts, or by their vitiated expansion. The eunuch is weak and timid, the beard is wanting, the voice shrill, and he seldom possesses a vigorous intellect. His whole personal configuration and mental disposition are approximated to those of females. On the other hand, where the essential organization of women is injured, there is some tendency by nature to remove them from their original sex. Cases of this kind can seldom occur, but such was the effect in the necessary extirpation of an ovary on account of disease; and also in another instance, where the full developement of the ovaries had not ensued. It is impossible to admit the last class of hermaphrodites, females with preternatural enlargements, accompanied by a hoarse voice, indications of a beard, flat breasts, and masculine propensities, along with women exhibiting none of these peculiarities. They are somewhat removed from females, as men whose person and mind are of a corresponding description, are somewhat removed from the entire and vigorous sex. The difference arises from sexual organization. It has also been conjectured by some learned authors, as Wrisberg, that women of masculine manner and appearance, and men exhibiting an extraordinary degree of effeminacy, may be divided into two distinct classes, the former characterised by ten, the latter by six, peculiarities, among which sterility is common to both. These he supposes to be dependent on sexual organization; and it is worthy of remark, that weakness of intellect is almost invariably concomitant on the imperfect expansion of the generative parts, whether this is prevented by natural infirmity, or by violence in childhood.

Perhaps all the varieties of configuration, which we have thus endeavoured to reduce to three classes, may be ranked in general under monstrosities. Nothing can be more interesting than to investigate the elements of sexual distinction. In whatever manner the expansion of these elements may be deranged, the result is monstrosity, as in other cases, by excess or defect, or some unnatural combination of what would constitute a male or female imperfectly developed. This vicious configuration, though for the most part the lot of some solitary individual, as other monstrosities, prevails in families where there are also perfect beings. One instance is given by Kauu Boerhaave in two young Siberians, and another by Sir Everard Home, in two children born in Devonshire. The latter were males with malformations: They were idiots, and they were of an uncommon size. The parents had an intermediate child, who was a perfect girl. HERMOPOLIS. See Civil Architecture.

HERNIA. See Surgery.

HEROD, King of Judea, surnamed the Great, on account of his power and talents, as it frequently happens, rather than of his virtues, was the second son of Antipater the Idumæan, and was born at Ascalon in Judea, about seventy years before the Christian æra. At the age of twenty-five, he was appointed by his father to the government of Galilee, where he distinguished himself by the suppression of a band of robbers, and the execution of their leader Hezekiah, with several of his comrades. Having performed this service of his own authority, and executed the culprits without even the form of trial, he was summoned to answer for his conduct before the Sanhedrim; but he escaped both punishment and censure, through the strength of his party, the zeal of his friends, and his own abilities and dexterity.

In the civil wars of Rome, Herod at first embraced the party of Brutus and Cassius, and was, in consequence, made governor of Cælesyria; and, after their death, when Mark Antony arrived victorious in Syria, he and his brother contrived to ingratiate themselves with him, and were appointed tetrarchs in Judea. But in a short time afterwards, in consequence of an invasion by Antigonus, who was assisted by the Jews, Herod was compelled to make his escape from Jerusalem, and to retire, first to Idumæa, and then to Egypt. He at length arrived at Rome, and upon occasion of a disputed succession to the crown of Judea, between the two branches of the Asmodean family, he found means through his own intrigues, and the influence and powerful recommendations of Mark Antony, to obtain a decree of the senate, conferring that kingdom upon himself. Immediately thereafter he repaired to Judea, and in the course of about three years, succeeded in getting possession of the whole country. But this success was not obtained without bloodshed. The throne was at that time in the possession of Antigonus; and, although aided by the Roman army, Herod was obliged to lay seige to Jerusalem, which held out for six months, when it was at length carried by assault, and a great slaughter made of the inhabitants. Antigonus was taken prisoner and put to death. The attention of Herod, upon assuming the government, was first directed towards the replenishing of his treasury, and repressing the Asmodean faction, by whom he was regarded as an usurper. In the pursuit of these objects, he was guilty of many oppressive acts of extortion and cruelty. Soon after this, an accusation was lodged against him before Mark Antony by Cleopatra, who, it is said, was influenced, upon this occasion, by his mother-in-law, Alexandra. Having been summoned to appear before the triumvir, to answer to the charges exhibited against him, he contrived, by great pecuniary sacrifices, to make his peace with Antony, and returned in high credit to his kingdom. It was upon this occasion that he displayed that conflict of passions, which for ever embittered his domestic life. Being distractedly fond of his wife Mariamne, and unable to endure the thought of her falling into the hands of another, he exacted a solemn promise from Joseph, whom he appointed to govern in his absence, that, if the accusation should prove fatal to him, he would put the queen to death. Joseph disclosed the secret to Mariamne, who, indignant at this savage proof of his affection for her, conceived from that moment a deep and settled aversion to her husband. Upon his return, some hints were thrown out respecting Joseph's familiarity with Mariamne during his absence. These suspicions he communicated to his wife, who immediately recriminated, and upbraided him with his cruel order concerning her. His fury then became unbounded. He put Joseph to death for betraying the secret confided to him, and threw his mother-in-law Alexandra into prison. About this time he received a visit from Cleopatra, who is said to have entertained amorous inclinations towards him. These, however, Herod did not gratify, but endeavoured to glut her avarice with profuse donations.

In the war which broke out between Antony and Octavius, Herod levied an army for the support of the former; but was obliged first to encounter Malchus, King of Arabia, whom he defeated, and compelled to sue for peace. After the decisive battle of Actium, his great object was to make terms with the conqueror; and, as a preliminary step, he put to death Hyrcan, the only surviving male of the Asmodean family. Having taken this precaution to secure himself, he embarked for Rhodes, and appeared before Augustus in all the ornaments of royalty, excepting his diadem. With all the appearance of noble and ingenuous confidence, he related the faithful services he had performed for his benefactor Antony, and hinted that he was ready to transfer his gratitude and allegiance to a new patron, from whom h eshould hold his crown and kingdom. Augustus was struck with the apparent magnanimity of this defence of his former conduct, and replaced the diadem on the head of Herod, who continued to be the most favoured of his tributary sovereigns.

But the good fortune which Herod experienced, as a prince, was poisoned by domestic broils, and particularly by the insuperable aversion of his wife Mariamne, whom at length he brought to trial, convicted, and executed. She submitted to her fate with all the intrepidity of conscious innocence, and was sufficiently avenged by the dreadful remorse of her husband, whose peace of mind was for ever afterwards destroyed. In vain did he endeavour to banish her memory by scenes of dissipation and cruelty: the charms of his beloved Mariamne haunted him wherever he went; and he would frequently call aloud upon her name, as if willing to forget that she was no longer among the living. At times he would fly from the sight of men: and on his return from solitude, which was ill suited to a mind stricken with the consciousness of guilt, he became more brutal and ferocious than ever, and in his fits of phrenzy spared neither friends nor foes. Alexandra, who had always exhibited the utmost malignity towards her daughter, fell the unpitied victim of his rage. At length he appears to have recovered some portion of self-possession, and employed himself in projects of regal magnificence. He built at Jerusalem a magnificent theatre and amphitheatre, in which he caused games to be celebrated in honour of Augustus; to the great displeasure of the zealous Jews, who discovered Gentile profanation in the theatrical ornaments and spectacles. These, and other offensive acts, excited a most serious conspiracy against him, which he, fortunately for himself, discovered, and exercised the most brutal revenge on all the parties concerned in it. He next built Samaria, which he named Sebaste, and adorned with the most sumptuous edifices; and for his security, he erected several fortresses throughout the whole of Judea, of which the principal was called Cæsarea, in honour of the emperor. At the dedication of this last new city, he displayed such profuse magnificence, that Augustus said, "his soul was too great for his kingdom." The same taste for sumptuous magnificence was exhibited in his palaces, on which he lavished the most costly materials and workmanship. To supply the place of his lost Mariamne, he married another wife of the same name, the beautiful daughter of a priest, whom he raised to the high rank of the supreme pontificate. His two sons by the first Mariamne he sent to be educated at Rome, and so ingratiated himself with Augustus and his ministers, that he was appointed imperial procurator for Syria.

With the view of acquiring popularity among the Jews, and of exhibiting an attachment to their religion, he undertook the vast enterprize of rebuilding the temple of Jerusalem, which he completed in the course of about a year and a half, in a noble style of magnificence. During the progress of this work he visited Rome, and brought back his sons, who had grown up to manhood. These, however, at length conspired against their father's person and government, and were tried, convicted, and executed. It was in reference to this transaction that Augustus is reported to have said, that "it was better to be Herod's hog than his son."

In the thirty-third year of his reign occurred the memorable event of the birth of our Saviour; upon which occasion, acccording to the Gospel of St Mathew, the jealousy of Herod was so highly excited by the prophetic intimations of the future greatness of the Messiah, that he slaughtered all the infants in Bethlehem, in hopes of destroying him among the number. About this time Antipater, returning from Rome, was arrested by his father's orders, and accused of treasonable practices. He was found guilty of conspiring against the life of the king. This and other calamities, combined with a guilty conscience preying upon a broken constitution, threw the wretched monarch into a loathsome and mortal disease, which has been represented by historians as a just judgment of heaven for the many foul enormities and impieties of which he had been guilty. In truth, his cruelty appeared to increase as he approached the termination of his career. A premature report of his death caused a tumult in Jerusalem; and those who had been imprudently concerned in it were immediately seized, and put to death, by order of the dying king. He also caused his son Antipater to be slain in prison, and his remains to be treated with every species of insult and ignominy. Even on his death-bed, he had planned a scene of more atrocious cruelty than he had ever devised or attempted at any former period of his life. He summoned the most considerable persons among the Jews to Jericho, and caused them to be shut up in the hippodrome, or circus, and gave strict orders to have them all massacred, as soon as he should have expired. "This," said he, "will provide for my funeral all over the land, and make every family in the kingdom lament my death." Fortunately, however, this savage order was not executed by those to whom it was entrusted.

Herod expired in the sixty-eighth year of his age, and the thirty-fourth of his reign. He bequeathed his kingdom to his son Archelaus, and left tetrarchies to his two other sons. The character of this monarch exhibits a combination of great talents and great vices. The success which attended his enterprizes, and which shed a false though dazzling lustre around his government, has given him an eminent rank in the list of sovereigns; while the savage disposition, which appears to have taken delight in the most revolting and horrible acts of cruelty, has consigned his memory to merited detestation. He was the first, it may be remarked, who shook the foundations of the Jewish government. He appointed the high-priests and removed them at his pleasure, without any regard to the laws of succession; and he entirely destroyed the authority of the national council. In short, his reign was similar to that of most able tyrants; splendid and glorious to outward appearance, but, in reality, destructive of the prosperity of the kingdom over which he presided. See Josephus, Prideaux, Lardner; *Univers. Hist.*; and *Gen. Biog. Dict.* (z)

HERODOTUS, the most ancient of the Greek historians whose works are extant, and thence called by Cicero the Father of History, was born at Halicarnassus in Caria, in the first year of the 74th Olympiad, or about 484 years B C. The name of his father was Lyxes; that of his mother Dryo. The city of Halicarnassus being at that time oppressed by the tyranny of Lygdamis, grandson of Artemisia, Queen of Caria, Herodotus quitted his country, and retired to Samos; from whence he travelled over Egypt, Greece, Italy, &c. collecting every where all the information he could procure concerning the origin and history of nations. He then began to digest the materials he had thus collected, and composed that history which has preserved his name and reputation even to our times. He is generally supposed to have written it in the island of Samos, where he studied the Ionic dialect, in which his history is composed; his native dialect being the Doric. He afterwards revisited his native place, and is said to have greatly displeased and irritated his countrymen, in consequence of having contributed, by his influence, to the overthrow of the government, and the expulsion of the tyrant Lygdamis, which obliged him again to go into exile. When he had attained his thirty-ninth year, he was induced, by the desire of fame, to recite his history to the people assembled at the Olympic games. It was received with universal applause, and procured him a general and permanent celebrity throughout all the states of Greece. The place and period of his death are uncertain; but it is probable that he died in exile in a town of *Magna Græcia*.

The history of Herodotus embraces a period of about 240 years, from the time of Cyrus the Great to Xerxes; and contains, besides the transactions between Persia and Greece, a sketch of the affairs of other nations, as of the Lydians, Ionians, Lycians, Egyptians, and Macedonians. The work is divided into nine books, which are called after the nine muses, not by the historian himself, but, as it is thought, by the Greeks at the Olympic games, when they were first recited, as a compliment to the author.

As an historian, Herodotus has been generally censured for betraying too great a partiality for the marvellous. But it may be remarked in his justification, 1*mo*, That the truth of many of the physical phenomena which he relates, and which were considered as incredible prodigies by the ancient writers, has been abundantly confirmed by modern discoveries; and, 2*do*, That Herodotus compiled a great part of his history from popular traditions, and expressly cautions his readers against an implicit belief of many of the wonderful things he relates upon the authority of mere hearsay. And it is an argument much in favour of this ancient writer, that his chronology requires less correction, according to Newton's Canons, than that of any of the subsequent Greek historians. With respect to those great transactions which took place in Greece after his own birth, he is generally thought to be worthy of credit; and the publication of his work, at a general assembly of the nation, may be considered as a voucher for his veracity. He has, nevertheless, been suspected of partiality in particular instances; and Plutarch, the most formidable of his critics, wrote a small treatise *On the Malignity of Herodotus*, in which he expressly taxes him with injustice towards the Thebans and Corinthians, and, indeed, towards the Greeks in general. His history, however, is still accounted one of the most precious relics of antiquity. The greatest inconvenience attending the perusal of this historian, results from his method and arrangement, which are extremely awkward, irregular, and discursive; some entire histories being introduced, by way of parenthesis, in the bodies of others. His style is easy, graceful, flowing, and copious even to exuberance. Its chief excellence lies in narrative, as it seems to want force and conciseness for sentiment and remark, in which he is surpassed by Thucydides. Herodotus is esteemed the model of the Ionic, and Thucydides of the Attic dialect.

Besides this work, Herodotus is supposed to have written an history of Assyria; which, if it was ever published, (which seems doubtful,) is now lost. The life of Homer, which is usually printed at the end of his works, has also been ascribed to Herodotus; but the best critics are of opinion that it is the production of a different author.

The two best editions of Herodotus are that of Wesseling, fol. Amsterdam, 1763; and that of Glasgow, in 9 vols. 12mo. 1761. A very excellent edition of Herodotus, in Greek and Latin, was published in Edinburgh by Mr Laing, in 7 vols. 12mo. in the year 1806, corrected by Professor Porson and Professor Dunbar. The *editio princeps* is that of Aldus, Venet. fol. 1502. There are two English translations of this historian; the one by Littlebury, in 2 vols. 8vo. and the other by Mr Beloe, in 4 vols. 8vo. with many useful and entertaining remarks and annotations. There is also an excellent French translation, with very learned notes, by M. Larcher. The geography of Herodotus has been examined and explained by the ingenious Major Rennell, in one volume 4to, 1800. (z)

# HERPETOLOGY.

HERPETOLOGY, from ἑρπετος, *a reptile*, and λογος, a *discourse*, is that department of ZOOLOGY, in which is considered the natural history and economy of reptiles.

Under the term *Reptiles*, naturalists have generally comprehended all those tribes of oviparous animals commonly called AMPHIBIA, including both oviparous quadrupeds and serpents; and accordingly Linnæus has arranged both under this name in his third class of animals. See AMPHIBIA.

In the present article, we mean to confine ourselves entirely to the first order of amphibia, according to the latest modification of Linnæus's system, or the oviparous quadrupeds, to which the term *Reptilia* has, though improperly, been restricted by the writers of the Linnæan school. We shall reserve the history of the serpent tribes for the article OPHIOLOGY.

The animals, of which we are now to consider the structure, economy, habits, and manners, belong to the second great division of vertebral animals, as characterized in our *Comparative* ANATOMY, namely, those with a single heart and cold blood. They have all articulated members, though, in a few instances, especially in one stage of their existence, these are only two in number, and very short. Many of them have tails, which, in some species, serve the purpose of hands, in others that of a fin or rudder. Most of them walk, or leap, or both; many swim with facility; and a few species are capable of supporting themselves in the air for a time, so as to imitate the action of flying. In these animals, the cavities of the chest and belly are not separated from each other, as in quadrupeds, by a fleshy partition or midriff.

In the reptile tribes we observe two remarkable circumstances, which will presently occupy a considerable share of our attention. These are, the great tenacity of life which they possess, and the extraordinary degree of reproductive power that prevails in many of the species. Several of them support abstinence, and apparently total seclusion from atmospheric air, for a surprising length of time; and even their heads and hearts are capable of being excited to muscular action long after they have been separated from the body. Again, when deprived of some less important organ, as the tail, a limb, or an eye, this is in no long period reproduced.

Though called *amphibia*, they do not all live equally well on land and in the water. Some prefer the former, and some the latter element, and a few seem fitted indifferently for either.

The general appearance and habits of these animals are not very prepossessing. Few of them possess that elegance of form and brilliance of colour, which we so much admire in most of the birds and in many of the quadrupeds. Lurid in their aspect, clumsy in their mien, and awkward in their gait, they tend rather to excite our abhorrence and disgust; and though few of them can properly be said to be poisonous, several are, from their bulk and ferocity, just objects of terror even to the human race.

Those who are fond of illustrating the idea of a regular scale or chain of being among the works of nature, may find several connecting links among the reptile tribes. Thus the crocodile may be said to connect the *viviparous* and *oviparous* quadrupeds, as resembling, in external appearance, the genus *manis*, or scaly lizards; the turtles, especially those with soft coverings, may be regarded as connecting the *cetacea* and reptiles; the flying lizards, or *dragons*, may be said to form the link of connection between reptiles and *birds;* the *seps* and *chalcis* nearly resemble *serpents ;* and the *siren* is so very near the *fishes*, that some naturalists still enumerate it among the finny tribes.

It is scarcely possible to point out correctly how many species of reptiles are known to naturalists at the present day; especially as many are considered *species* by one writer, and only *varieties* by another. According to the latest edition of Linnæus's *System of Nature*, only 170 species were *then* known; but in the systematic work of a late French writer, Daudin, the distinct species enumerated or described exceed *three hundred*.

## HISTORY OF THE SCIENCE.

MANY of the reptiles are noticed in the oldest writings that have escaped the ravages of time, or the destructive ignorance of barbarians. Several are alluded to in the Sacred Scriptures; and we are clearly of opinion with Scheuchzer (*Natural History of the Book of Job**) and Dr Young, (*Notes on his Paraphrase on Job*,) that the sublime description of leviathan, given in the 41st chapter of the book of Job, applies to no other animal with which we are acquainted, if not to the crocodile. His ample jaws and dreadful teeth, his compact impenetrable scales, his large and fiery eyes, his strength, ferocity, and courage, agree exactly with our best descriptions of the crocodile; and though some passages might lead us to conclude that the poet was describing an inhabitant of the ocean, this objection is trivial, when we reflect that the large rivers and lakes, which form the ordinary habitation of crocodiles, might, in the glowing and figurative languages of the East, without too much hyperbolical exaggeration, be designated by the terms *deep* and *ocean*.

Of the ancient classic naturalists who have written on reptiles, we need mention only Aristotle and Pliny. The former, in his *Historia Animalium*, has described the crocodile, the salamander, and some other species; but the latter, in his *Historia Naturalis*, has furnished the fullest account of reptiles, especially in his second, eighth, ninth, tenth, and twenty-eighth books, in which he relates all that was then known, and all that was believed, respecting the crocodile, the sea and land tortoises, the chameleon, and the basilisk. In the second book, he shows himself acquainted with the fact, that reptiles are not destroyed by cutting off their limbs or tail; in the eighth, he mentions the spectacle of five living crocodiles exhibited by Scaurus, the edile, to the people of Rome; in the ninth, he describes the mode then practised in India for taking turtles; in the tenth, speaking of the crocodile, he tells us very gravely, that the male and female sit alternately on the eggs laid by the latter; and in the twenty-eighth, besides mentioning the utility of the skink, and several parts of the crocodile, as medicines, he details at considerable length the fabulous history of the chameleon.

* See his *Physica Sacra*, published in 1731.

Among the modern writers on natural history, Gesner, in part of his *Historia Animalium*, treats of oviparous quadrupeds, though the number which he describes is by no means very considerable. As usual with the writers of his time, he imitates the ancient naturalists in mingling truth with fable, especially in his second book, in which he describes the chameleon. In some respects, however, he is very judicious. He notices the wonderful tenacity of life in reptiles, and particularly exemplifies it in the heart of the salamander.

About the same time with Gesner, viz in the middle of the 16th century, lived Rondelet, a native of Languedoc in France; who, in his work on fishes, has described some species of turtles as having been seen by him upon the coast of France.

That laborious collector and compiler, Aldrovandi, in that portion of his works which is dedicated to quadrupeds, describes many reptiles, especially the tortoise, the crocodile, the chameleon, and the salamander; but as his accounts are derived almost entirely from preceding authors, and abound with marvellous fictions, they are now rarely consulted.

In that part of Johnston's *Historia Animalium* which s dedicated to *quadrupeds*, we have also an account of several reptiles, among others the crocodile and the chameleon.

In the latter end of the 17th century, Blasius published his *Anatomia Animalium figuris variis illustrata*, which contains some useful observations on the structure of reptiles. He particularly remarks the imperfection of their secreting organs. He also describes the manners of a tame tortoise which he kept, and its remarkable abstinence.

About the same time appeared Sibbald's *Prodromus Historiæ naturalis Scotiæ*, in which he describes some species of *turtles* as being found on the western coast of Scotland.

In 1685, Francis Redi published his *Experimenta circa Varias res Naturales*, and about the same time his Italian work on the same subject. The experiments which Redi made on various species of tortoise are sufficiently cruel; but they illustrate, in an eminent degree, the surprising tenacity of life possessed by these animals. They will be particularly noticed hereafter.

Our learned and scientific countryman, Ray, was the first naturalist who gave any thing like a rational account of reptiles, in his *Synopsis Animalium*. He describes more species of tortoise than were known before; and, besides the crocodile, enumerates several rare species of lizards.

The immortal Swedish naturalist, in his *Systema Naturæ*, divided the class of amphibia into four orders,—reptiles having feet, serpents without feet, gliding reptiles, (*meantes*,) and swimming reptiles, (*nantes*). As the last order was afterwards removed to the class of fishes, and some other important emendations were introduced into subsequent editions of that laborious work, we shall defer any observations on Linnæus's method till we notice his last and best editor, Gmelin.

In Seba's *Thesaurus Naturæ*, published about the middle of last century, a considerable number of the most remarkable reptiles is figured; and though the engravings are not in the first style, they give a sufficiently just idea of the objects which they represent.

All the British species then known are described, and some of them figured in the *British Zoology* of Pennant, published in 1749, in 4 vols. He particularly describes the coriaceous, or *leathern turtle*, as having been found on the British coast.

Mr Pennant also contributed some of the very few papers on reptiles to be found in the *Philosophical Transactions*, especially a description and figure of the *Testudo ferox*, or soft tortoise, and the *T. coriacea*, or leathern turtle. Some species are also noticed in his *Arctic Zoology*.

In 1755, professor Klein of Leipsic published his *Tentamen Erpetologiæ;* but as that work is confined chiefly to serpents, we cannot properly do more than notice it here.

In 1768, appeared the *Specimen Medicum exhibens Synopsin Reptilium* of Laurenti, in which a new arrangement of these animals was attempted. He distributes all reptiles (except tortoises, which he unaccountably omits altogether) into three orders,—*leaping reptiles*, *walking reptiles*, and *serpents*. Of the first order, he characterizes five genera, *Pipa*, *Bufo*, *Rana*, *Hyla*, and *Proteus;* and in his second order, thirteen genera, viz. *Triton Salamandra*, *Caudiverbera*, *Gecko*, *Chameleo*, *Iguana Basiliscus*, *Draco*, *Cordylus*, *Crocodilus*, *Scincus*, *Stellio*, *Seps*. Among the serpents he places the *Chalcides*, which certainly belong to the second as properly as the *Seps*.

Nine years after the "Specimen" of Laurenti, Scopoli published his *Introductio ad Historiam Naturalem*, in which he divides the reptiles into legitimate or true, and bastard or spurious reptiles, the latter term being applied to the cartilaginous fishes. The true reptiles, including serpents, he divides into two classes; the first containing the serpents, and the second the subjects of our present inquiry. This latter he subdivides into two orders. The first order comprises those reptiles that have tails, viz. the siren, lizards, dragons, and tortoises, including under lizards the crocodiles, iguanas, cordyli, salamanders, chameleons, and skinks. The second order contains only one genus, *Rana;* but this comprehends toads and tree frogs. The chalcides he ranks among the serpents.

In 1789, Professor Gmelin published his edition of Linnæus's *Systema Naturæ*. In this work, which, though little more than a compilation, reflects much credit on the industry and abilities of its author, the *amphibia* are divided into two orders, reptiles and serpents. The reptiles are characterized as being furnished with feet, respiring by means of lungs or gills, and having a simple penis.

Of the reptiles, he forms only four principal genera, viz. *Testudo*, *Draco*, *Lacerta*, and *Rana;* but most of these are subdivided. Of the tortoises, there are three subdivisions, *sea tortoises*, *fresh water tortoises*, and *land tortoises*. Of the genus *Lacerta*, there are eleven subgenera; *crocodiles*, *cordyli*, *stelliones*, *iguanas*, *salamanders*, *geckos*, *chameleons*, *ameivas*, *lizards*, *skinks*, and *chalcides*. Of the genus *Rana*, there are three subdivisions: *bufones*, or land toads; *ranæ*, or frogs; and *hylæ*, or tree frogs.

The principal defects of this arrangement are, the ranking the salamanders among the *Lacertæ*, from which, as will appear hereafter, they are separated by well marked characters; and omitting the *siren*, which Gmelin has placed in the genus *Murena*, among the fishes. For the small number of his species Gmelin is scarcely accountable, as many have been discovered since his time; and for the small number of his *genera*, his numerous subdivisions in a great measure compensate. It is of little consequence whether we call these *genera*, or *sub-genera*. The effect of the subdivisions in ascertaining the species is much the same; and this, added to their scientific accuracy, is one great merit of the French naturalists, whose writings we are presently to notice.

That part of Gmelin's work which comprises the *Animal Kingdom* has been translated, with some additional matter, by Dr. Turton, and published in four thick volumes 8vo.

In 1788 and 1790, the Count de Lacepede published his *Histoire Naturelle des Quadrupedes Ovipaires et Serpens.* This work had been projected by Buffon as a sequel to his Natural History, general and particular, and he had collected considerable materials towards its composition; but finding himself unable to pursue the arduous task, he deputed Lacepede to supply his place, and caused the materials to be put into his hands. The result shewed how ably Buffon had selected his successor; for, though since this work was published much additional information has been obtained, and many scientific improvements introduced into systematic Herpetology, the work of Lacepede will long be regarded as one of the most classical and elegant publications on this part of natural history.

The whole work is divided into two nearly equal parts, which may be considered as distinct and independent treatises, each being prefaced by a preliminary discourse. The first part, with which we alone are at present concerned, treats of oviparous quadrupeds; and these are classed under four géneral heads, tortoises, lizards, oviparous quadrupeds without tails, and two-footed reptiles, each being more or less subdivided. The tortoises have only two subdivisions: 1st, *Sea tortoises*, of which six species are described; and 2d, *Fresh water* and *land tortoises*, of which there are twenty species noticed. The lizards are divided into, 1st, Those which have flat tails, and five toes before, including four species of crocodile, the dragon, tupinambis, and five other species; 2d, Those which have round tails, five toes before, and a crested back, comprehending the guana, the basilisk, the agama, and three other species; 3d, Those that have round tails, five toes before, and fillets on the belly, containing eight species, among which are the cordylus and ameiva; 4th, Those that have five toes before, but no transverse bands on the belly, including the chameleon, the skink, and twenty other species; 5th, Those having large imbricated scales on the under surface of the toes, containing the geckos and two other analogous species; 6th, Those that have only three or four toes, to which belong the seps and chalcides; 7th, Those that have membranous wings, the dragon or flying lizard; 8th, Those which have three or four toes on each fore foot, and four or five on each hind foot, including the salamander, ask, and four others.

Of the oviparous quadrupeds without tails, there are three subdivisions: 1st, Frogs having their heads and bodies angular and elongated, of which there are thirteen species; 2d, Tree frogs, having a small viscous pellet under each toe, comprehending seven species; 3d, Toads with compact rounded bodies, of which there are fourteen species, including the pipa, or Surinam toad. The last head, which is not subdivided, contains only two species.

This work of M. Lacepede was translated into English by Mr Kerr, and published at Edinburgh in 4 vols. 8vo. in 1802.

In 1792 was published at Erlang, the *Historia Testudinum* of J. D. Schoepff, an excellent work, left imperfect by the death of its ingenious author.

We must not here omit to notice two ingenious publications in Latin on the physiology of reptiles, by Dr Robert Townson: 1st, *De Amphibiis*, published at Gottingen in 1794: and 2d, *Observationes Physiologicæ de Respiratione Amphibiorum*, published at Vienna in 1796.

According to Daudin, the most natural classification of reptiles that has yet appeared is that of M. Alexandre Brongniart, published in 1799 in the *Magazin Encyclopedique*. As we shall fully explain this classification, after having noticed the principal naturalists who have adopted and modified it, we shall here merely give an outline of this author's subdivisions. He distributes all reptiles under four general orders: *Cheloniens*, or tortoises, of which he makes two genera, *Chelonia* and *Testudo*, corresponding exactly thus far with the division of Lacepede; 2d, *Sauriens*, of which there are nine genera, viz. *Crocodilus*, *Iguana*, *Draco*, *Stellio*, *Gecko*, *Chameleo*, *Lacerta*, *Scincus*, and *Chalcides*; 3d, *Ophidiens*, or serpents; and 4th, *Batraciens*, of which there are four genera, *Rana*, *Bufo*, *Hyla*, and *Salamandra*.

At the very commencement of the present century, M. Latreille published *L'Histoire Naturelle des Reptiles*, the arrangement of which differs little from that of Lacepede, except in placing the Salamander under the same head with the frogs and toads, and a species of Proteus, which appears to be a tadpole of the water salamander, and the Siren, among the serpents. His generic characters, however, are more precise than those of Lacepede; but his method, on the whole, is inferior to that of Brongniart. M. Latreille also published *L'Histoire Naturelle des Salamandres*.

Between the years 1800 and 1803, the celebrated anatomist and naturalist Cuvier, and his disciple and assistant Dumeril, published his *Leçons Anatomie Comparée*, in 5 vols. 8vo. with 52 plates at the end of the fifth volume. Cuvier had, in 1798, published an elementary work on natural history, under the title of *Tableau Elementaire de l'Histoire Naturelle des Animaux*, in which he gave a general description of reptiles.

Attached to the first volume of his Lectures, Cuvier has given a systematic arrangement of the various classes and orders of animals; and in the classification of reptiles, he has adopted an arrangement radically the same with that of Brongniart. In the first place, he divides reptiles into two sections; 1st, Those which have two auricles to the heart; 2d, Those that have but one. Each of these sections is subdivided into two orders. The first order consists of those reptiles that have a shell or carapace, and their jaws defended by horn. These are the *cheloniens*, or tortoises. The second order consists of those that have the body covered with scales, and are furnished with teeth, like the *sauriens*, or lizards, the genera of which are, with the addition of seps, the same with those of Brongniart. The first order of the second section contains the serpents. The second order comprehends those reptiles that have a naked skin, feet, and gills, at an early stage of their existence. Of this order (the Batraciens) there are three families; *Rana*, or frog, including the three subgenera of *Rana*, *Hyla*, and *Bufo*; *Salamandra*, including the sub-genera of *Salamandra* and *Triton*; and *Siren*.

These excellent Lectures contain a very full account of the anatomical structure and physiology of reptiles, and to them we are almost entirely indebted for our chapters on that subject. The first two volumes of this work were translated into English under the inspection of Mr Macartney, lecturer on comparative anatomy in London, and published there in 1801.

In 1800, Dr George Shaw began his *General Zoology*, which was intended to include all the genera and species of animals at present known. The third volume contains the reptiles and serpents. In giving our opinion of this extensive work, we are somewhat at a loss. As a systematic arrangement of animals, it is very defective, and the references to other authors are extremely few. As a popular descriptive work, it is scarcely deserving our attention; for, though almost all the species are described, as well as figured, there is scarcely any thing like a history of the species. The arrangement is that of Linnæus, and the characters are in general derived from Gmelin's edition of the *Systema Naturæ.* The work, however, abounds in excellent plates, the figures of which are in general well delineated, and beautifully engraved.

We need scarcely mention the *Naturalist's Miscellany* of the same author, as but few reptiles are there figured.

Perhaps the most complete account of reptiles, up to the present day, has been given by M. Daudin, who has long devoted most of his attention to this part of zoology, and has published several treatises on the subject. Besides his *Histoire Naturelle des Reptiles*, published separately, and the sequel of the same work, entitled *Histoire Naturelle des Rainettes des Grenouilles, et des Crapauds*, he has contributed eight volumes octavo, with numerous plates, to the voluminous and expensive collection of natural history published by Sonnini. These volumes were published at different times, from 1802 to 1805. The first volume contains some historical notices of several writers on Herpetology, and a copious introductory treatise on the structure and physiology of reptiles, illustrated by fifteen plates. The second volume contains the natural history of the Chelonian order, in which are described fifty-seven species of *tortoise;* and the same volume commences the history of the Saurian order, and describes seven species of *crocodile.* In the third and fourth volumes, the history of the Saurian order is completed, by a description of one species of *Dracæna*, fourteen of *Tupinambis*, thirty-two of *Lacerta*, two of *Takydromus*, three of *Iguano*, three of *Draco*, two of *Basiliscus*, twenty-five of *Agama*, nine of *Stellio*, eight of *Anolis*, fifteen of *Gecko*, four of *Chamæleo*, twenty-one of *Scincus*, six of *Seps*, and four of *Chalcides.* The fifth, sixth, and seventh volumes are occupied with the Ophidian order, or *serpents*, and the eighth completes the work with the history of the Batracian order, containing a description of twenty-seven species of *Hyla*, sixteen species of *Rana*, thirty-two of *Bufo*, fourteen of *Salamandra*, one of *Proteus*, and one of *Siren.* The specific characters in the body of the work are in Latin; but, at the end of the eighth volume, the whole genera and species are arranged together, with their characters in French, under the title of *Tableau Methodique des Reptiles.*

Daudin's Natural History of Reptiles has considerably increased the number of species, and has brought us acquainted with many that were either not known before, or whose place in the systematic arrangement had not been distinctly ascertained. Though the matter of this work is excellent, we cannot, however, say so much for the execution of the plates. The figures are in general so deeply shaded, as to render it difficult to observe the characteristic lines, scales, and dots, that distinguish the species.

Dumeril, whom we have already noticed as the assistant of Cuvier, has published two works on natural history, which contain, among other animals, the new systematic arrangement of reptiles. These are, *Zoologie Analytique*, published in 1806, and *Traité Elementaire d'Histoire Naturelle*, in two volumes, of which the second contains the animal kingdom. His arrangement is so near that of the other distinguished naturalists of the French school, that we need not detail it here, especially as we have already given a summary view of it under the article Amphibia.

We might have extended these historical notices to a much greater length; but we consider it unnecessary. We have given a succinct account of the principal writings on Herpetology, and shall now conclude this Part of our subject with a list of other works, to which the reader may refer for additional information.

On the anatomy, physiology, and classification of reptiles, see Swammerdam, *Biblia Naturæ;* Rœsel, *Historia Naturalis Ranarum;* Schneider, *Amphibiorum Physiologiæ Specimen;* and his *Historia Amphibiorum;* Caldesi, *Osservazioni Anatomiche intorno alle Tartarughe;* Spallanzani, *De Fenomini della Circolatione;* his *Tracts on the Natural History of Animals and Vegetables;* and his *Memoires sur la Respiration*, lately publisned by Sennebier; Blumenbach, *Abbildungen Natur Historischer gigenstande;* and his *Handbuch*, or manual of the same subject; Schmid, *Historia Testudinum;* Daubenton, *Dictionaire d'Erpetologie*, forming a part of *L'Encyclopedie Methodique;* Perault, *Memoires pour servir à l'Histoire Naturelle des Animaux;* Humboldt, *Recueil d'Observations de Zoologie et d'Anatomie comparée;* Walbaum, *Chelonographia;* the compendious System of Comparative Anatomy translated from Blumenbach, with much additional information from Cuvier, and lately published by Mr Lawrence; Ellis's *Inquiry into the changes produced in Atmospheric Air by Respiration, &c.;* several papers by Cuvier, Geoffroy, Daudin, Lacepede, &c. in the *Annales de Museum d'Histoire Naturelle*, more particularly in the 2d, 10th, 12th, and 14th volumes, and a single paper by Mr Revet Sheppard on the British lizards, in the seventh volume of the *Linnean Transactions.*

On the history and manners of the species, much interesting information may be derived from Sloane's *Natural History of Jamaica, Barbadoes, &c.;* Brown's *Natural and Civil History of Jamaica;* Catesby's *Natural history of Carolina;* Russel's *Natural History of Aleppo;* White's *Natural History of Selborne;* Cetti, *Storia Naturale della Sardegna*, or his *Historia Amphibiorum et Piscium Sardiniæ;* Bingley's *Animal Biography*, vol. iii.; Forskal, *Fauna Arabica*; and the Voyages or Travels of Hasselquist, Bruce, Sonnini, Olivier, Cook, Stedman, Bartram, Denon, Barrow, Marchand, &c.

Before commencing our account of the structure and economy of reptiles, it is necessary, in order to render that account intelligible, that we should here give a comprehensive view of the arrangement which we mean to follow in the Second Part of this article.

On carefully comparing the various arrangements of reptiles which have been adopted by modern naturalists, we are disposed to prefer that of the French school, though we think it unnecessary to carry the subdivision of the genera so far as has been done by Dumeril and some of his associates.

Exclusive then of the serpents, which, as we have seen, constitute the third order in this new arrangement, the reptile tribes are distributed into three orders, Chelonians, Saurians, and Batracians.

The Chelonians have a short, thick, oval body, covered with a horny shell or membranaceous coat. The upper or *dorsal* part of this is called the *shield*, and is formed of the vertebræ and ribs, cemented together within or beneath the outer covering; and the lower or *sternal* part is called the *breastplate.* The head is supported by a pretty long neck, and the mouth is furnished with two mandibles, generally resembling the bill of a bird. These tribes are in general slow in motion, possess little sensibility, and have a languid circulation and slow respiration. They live chiefly on vegetables. They generate by copulation, in which act they remain for several days. Their eggs are covered with a shell, and are deposited by the female in the sand, or among loose earth or gravel. The young are hatched in the form which they are to preserve through life.

The Chelonian order is divided by Dumeril into four genera, *Chelonia*, *Emys*, *Chelys*, and *Testudo;* but as the third of these comprehends only one species, and the second is distinguished from the fourth only by a few minute differences, we shall continue the division of Cuvier into two genera, *Chelonia* and *Testudo;* the former comprehending the sea tortoises, or turtles, which have the articulated members in the form rather of swimming paws than feet; and the latter, or the tortoises, having feet more or less digitated, and furnished with distinct claws.

The Saurians, or lizards, have a lengthened scaly body, feet armed with claws; a tail that is often of considerable length, and the jaws beset with teeth. Their legs are in general short; and consequently their pace, though quicker than that of the former order, is slower than that of most quadrupeds; and as their legs are set wide from the body, their progress is unsteady and oblique. The reptiles of this order also copulate, and deposit their eggs to be hatched by chance. The young are extruded in a perfect state.

Of the Saurian order, Daudin reckons sixteen genera, which we shall divide, with Dumeril, into two Sections, *Plani caudata*, or flat tailed, and *Tereticaudata*, or round tailed. Of the flat-tailed Saurians we have four genera: *Crocodilus*, having a flattened head, the scales on the back of unequal size, and the hind feet palmated; *Dracæna*, having a square head, and toes distinct; *Basiliscus*, having equal dorsal scales and a crested ridge along the back, supported by bony rays; and *Tupinambis*, having equal scales but no dorsal ridge. Of the round-tailed section there are twelve genera, viz. *Iguana*, having a crest on the back, and a serrated crest on the throat; *Draco*, having the sides furnished with membranes resembling wings; *Agama*, having an oblong scaly body and tail, an inflated throat, and the feet long and thin, each furnished with five slender separate toes; *Stellio*, having a spinous tail covered with carinated scales; *Chameleo*, having feet formed for climbing; *Gecko*, having a thick body, and a throat capable of being dilated by inflation; *Anolis*, having a long thin body, and dilatable throat; *Lacerta*, having a plated head, but no inflation of the throat; *Takydromus*, having the body long and thin, and a row of very small granular pores along each thigh; *Scincus*, having a long scaly body and tail, and distinct legs; *Seps* and *Chalcides*, agreeing in having a very long and slender body, with either two or four very small short feet, and differing in some minute particulars, which will be noticed hereafter.

In the third order, Batracians, the body is naked, *i. e.* covered neither with shell nor scales; the feet are always distinct and without claws; the two sexes do not enter into perfect copulation, and the young undergo a metamorphosis.

This order is subdivided into two sections, those without tails, and those with tails, and in each of these sections are reckoned three genera.

The genera of the Batracians without tails are *Hyla*, or tree-frog, having a long body a little compressed; a short fleshy tongue; four toes on the fore feet, terminated by lenticular knobs; *Rana*, or frog, differing from the former in having the toes pointed and not knobbed; and *Bufo*, or toad, having a thick broad body beset with warty tubercles, especially two upon the neck. The genera belonging to the second section are *Salamandra*, having a long body terminated by a tail that is generally cylindrical, three or four toes on the fore feet, and five on the hind; *Proteus*, having a long body terminated by a compressed fin-like tail, three toes on the fore feet, and two on the hind, with persistent branchiæ; and *Siren*, having a lengthened body, a compressed fin-like tail, fore feet furnished with claws, but no hind feet and persistent branchiæ.

## Part I. ON THE ANATOMY AND PHYSIOLOGY OF REPTILES.

Having now given a general description of reptiles, and explained the classification which we intend to follow in the subsequent pages; we shall proceed to exhibit a comprehensive view of their anatomy and physiology, pursuing the same order which we have observed in the comparative part of our Anatomy.

### CHAP. I.

#### *Of the Motions of Reptiles.*

The organs of motion in reptiles, do not differ so much from those of quadrupeds as some other parts of their organical structure, though there is considerable variety in the several tribes of this class.

The bones of most species are as firm as those of quadrupeds; but in the smaller reptiles, as the frogs, they are more cartilaginous. It is asserted by some naturalists, that the bones of tortoises have no medullary cavities; but in the larger lizards, these are sufficiently apparent. The skeleton of a Saurian reptile is figured in Plate CCXCV. Fig. 1.

The skull of reptiles is generally very small in proportion to the body; but in many species, the jaws are proportionally very large. The cavity of the skull is either exceedingly small, or not half filled by the brain. A remarkable change takes place in the head of the crocodile, in proportion as the animal advances in growth after its extrusion from the shell. When first hatched, the skull is thick and rounded, and the forehead prominent, and the eyes are nearly at an equal distance between the fore and back parts of the head. In proportion as the animal grows, the frontal prominence gradually disappears, and the jaws lengthen forwards; and in the adult state, the head is quite flat, and the eyes three times as far distant from the snout as they are from the back of the head.

The skull of the crocodile resembles a truncated pyramid, of which the cavity for the brain forms the base; that of frogs and salamanders is of a form between the cylindrical and the prismatic; that of tortoises considerably resembles that of the crocodile. The cavity of the skull, in reptiles, is of an oblong form, and nearly of an equal breadth. Of the jaws and teeth, we shall speak under the organs of digestion.

With respect to the vertebral column, we may remark, that the number and proportions of its component vertebræ vary more in this class than in all the other vertebral animals. The tortoises have generally seven vertebræ in the neck, from eight to eleven in the back, and generally three or four in the sacrum. In this genus all the vertebræ, except those of the neck and tail, are immoveably fixed with what is analogous to ribs, in the horny shield with which they are covered. The crocodile has seven cervical, twelve dorsal, five lumbar, two sacral, and thirty-four caudal vertebræ; but in the other saurians, the proportional numbers vary in almost every species. Frogs and toads having no ribs, the ordinary division of the vertebral column cannot be distinctly made. The common frog has in all ten vertebræ, and the pipa, or Surinam toad, has in all eight.

The muscles attached to the spine also vary considerably. In tortoises, where only the head and tail are moveable, the spinal muscles are confined chiefly to these two organs, and those of the neck possess many peculiarities. The chief motions of the neck in this genus are those by which the head is thrust out from the shell, and drawn back within it. The spinal muscles of frogs and salamanders are few in number, except that, in the latter, the crocodiles, and other saurians, the muscles of the tail are proportionally numerous and powerful.

The thorax is very differently formed in the different orders. In the tortoises, the sternum or breast bone is lost in the breast plate or lower shell, while the ribs are, as we have said, firmly cemented in the shield. Of the saurians, the crocodile has the anterior part of the sternum bony and prolonged, so as to receive the clavicles; while the rest is cartilaginous, and extends backward to the pubis, furnishing eight cylindrical cartilages that surround the belly. The ribs of this animal are twelve in number; but the two most atlantal or forward, and the two most sacral or backward, are not united to the sternum. In the guana and tupinambis, only six of the ribs are united to the sternum. The chameleon has a small sternum, but all the ribs are made to meet round the thorax, by means of intermediate cartilages. In the salamanders the ribs are extremely short, so as to appear like appendages of the vertebræ. The frogs have a sternum, though no ribs.

In most of the reptiles, there is little peculiar in the muscles of the thorax and abdomen. In the tortoises, however, where the ribs are immoveable, and where the place of abdominal muscles is supplied by the breast plate, the muscles which would be attached to the sternum are inserted into the pelvis, upon which they act; and in frogs, which have no ribs, the muscles are united to the sternum by strong membranes.

The superficial or glenoid cavity, in which the humerus or large bone of the atlantal or anterior extremity moves, is in reptiles formed partly by the scapula, and partly by the clavicle. The scapula has no spine; it is elongated, and retracts and becomes thicker towards its neck. The clavicle is simple, short, and flat. In tortoises, the disposition of the bones that form the shoulder is most remarkable, and is thus described by Cuvier. Besides the scapula and the clavicle, there is a bone which he calls the *fork;* one of the bones stretches from the base of the rudiment of the first rib, to which it is attached by a ligament as high as the glenoid cavity, where it is intimately united with the other two. The second bone, which appears like the continuation of the former, is attached by its other exteremity to the breast plate, and this extremity is bound by strong ligaments to that of the bone behind it. These bones thus united are slightly curved outward, so as to leave between them and those on the opposite side an oval space, for the passage of the gullet, the windpipe, and numerous muscles. Lastly, the third bone is placed below the abdominal and thoracic viscera, nearest the breast plate, and is extended from the glenoid cavity as far as the abdomen. It gives attachment to numerous muscles, and resembles the scapula in every thing but situation. See Cuvier, *Leçons d'Anat. Comparée*, Sec. IV.

The humerus presents nothing remarkable, except in the tortoises, where it is united, somewhat in the manner of birds, with the scapula, the clavicle, and the fork.

In the tortoise tribes, numerous and strong muscles are attached to the humerus; while in frogs many of the muscles which are found in this region in quadrupeds are wanting.

The distal part of the atlantal extremity, or what comparative anatomists chuse to call the fore-arm, consists, as in quadrupeds, of two bones, except in the frog and toad. These are analogous to the radius and ulna, but have several peculiarities of structure. In particular, the tortoises have them so fixed in a state of pronation, as to confine the action of these extremities to swimming.

What is called the hand or paw is in reptiles considerably varied. In the sea turtles or chelonians, it is whole without, though consisting within of many separate bones. In the saurians it is digitated, and consists in some species of five divisions, in others of four, three, and even one: these toes are generally furnished with claws. These digitated paws, according to the number, length, and armour of their divisions, are adapted to the various actions of walking, climbing, grasping, and seizing, or tearing prey.

The pelvis, and especially that part of it which corresponds to the pubis, is of considerable size, and it is extraordinary, that in these animals the pelvis is moveable on the vertebral column.

The thigh bone of reptiles is similar to that of other animals, except that it has a double curvature, more or less remarkable, presenting a convexity forward towards the tibial or distal extremity, and a concavity towards the pelvis. In the tortoises it has well marked trochanters; but these are wanting in lizards and frogs. It is generally round, except in the Surinam toad, in which it is much flattened. There are few peculiarities in the muscles of this region.

The leg is composed of a tibia and fibula, distinct throughout their whole length, except in frogs, in which they are united. When separate, they are nearly of equal size, and in general are articulated immediately with the thigh bone. The muscles of the leg are most remarkable in the turtles and frogs. In the former, they are adapted to the act of swimming; in the latter, they form a prominence behind, resembling the calf of the leg in man. The bones and muscles of the hinder feet are in most cases similar to those of the paws.*

From the very different form and position of the limbs of reptiles, their progressive motions, and even their mode of standing, vary considerably in the different tribes and species. In standing, turtles rest as much on their breast-plate as on their paws, while the land tortoises stand with their belly a little above the ground. The *batracians*, and especially frogs, rest in a kind of sitting posture, with the fore part of their body elevated on the fore legs. Those lizards, whose bodies resemble those of serpents, as the *chalcides*, are coiled up in a state of rest.

The turtles rather scramble than walk, like seals; but tortoises walk well, though slowly. Some saurians move along with great agility, while others, as the crocodile, have a comparatively slow progression. Few reptiles climb well, if we except the chameleon, which is much assisted by its prehensile tail. The guanas and tupinambes are the best leapers among the saurians; and frogs and toads, though they cannot walk well, are excellent jumpers.

A great variety of reptiles swim well, especially turtles, crocodiles, and frogs. The only species that can be said to fly is the dragon, whose motion through the air resembles that of the flying squirrels.

* In the twelfth volume of the *Annales de Museum*, is an elaborate Memoir by Cuvier on the Osteology of the crocodile, to which we refer the reader for details, which it would be inconsistent with our plan to introduce in this place.

## CHAP. II.

### *Of Sensation in Reptiles.*

As the cavity of the cranium in reptiles is very small, and not nearly filled by the brain, it follows that the size of this organ is very inconsiderable. It is calculated that, in the turtle, the brain is little larger than $\frac{1}{5000}$ part of the whole body, though in the frog it is proportionally much larger, being as 1 to 172. It consists chiefly of five rounded eminences, without convolutions, and with a smooth base. There is no *corpus callosum*, *fornix*, *pons varioli*, or *arbor vitæ*; and what are called the *thalami* of the optic nerves, are situated behind the hemispheres. The distribution of the nerves in the head has no remarkable peculiarities.

The number of spinal nerves in the different orders and tribes of reptiles, is proportional to the number of vertebræ of which the spinal column is composed, and their distribution is so little different from that in man and quadrupeds, that it need not be here described. The nerves of the atlantal, or fore legs, are derived from the cervical nerves, and sometimes the dorsal, uniting to form a brachial plexus or net-work. Those of tortoises are extremely complex; those of lizards more simple; and those of frogs proceed from a very thick cord coming from between the second and third vertebræ, and forming the largest nerve in the body.

The nerves of the sacral extremity in lizards, after emerging from the pelvis, form a single cord, which runs down the inside of the thigh, and thence supplies the leg and toes. In frogs this large cord passes to the posterior part of the thigh, like the sciatic nerve in man.

It appears that reptiles possess all the five senses found in the other vertebral animals, though in very different proportions and degrees. Their sight appears to be very acute, and their eyes are in general large and prominent. The sense of hearing, if we may judge from their want of external ears, is much less perfect than that of sight. Their smelling is supposed, for a similar reason, and from the little use they appear to make of this sense in seeking their food, to be still less acute; and it is doubted whether many of them possess the faculty of tasting at all. With respect to touch, it is probable that those which have soft skins and digitated feet possess considerable acuteness in that sense; while those which have scaly, shelly, or coriaceous coverings, and more especially the turtles, are capable of exercising touch in a very slight degree, if at all. We shall examine the organs of all these senses in the order which we have laid down in the article ANATOMY, and exemplified in CETOLOGY, except that we shall defer the organs of feeling, if they deserve that name, to the head of *Integumation*.

All reptiles appear to possess a tongue, but it varies much in substance and degree of mobility. In the tortoises, it is covered on the upper part with long soft close papillæ, giving it the appearance of velvet. In crocodiles, these papillæ are extremely short, and more like wrinkles. In these animals it is entirely fleshy, but is so completely attached by the point and edges to the basilar or lower jaw, as to admit of scarcely any motion; and it was long doubted whether crocodiles had a tongue. In stelliones, again, it is very moveable; and in the common lizards, and the tupinambes, it it considerably extensile. In these latter reptiles, the tongue terminates in two long flexible cartilaginous points; and in the skinks and geckos it is notched at the tip.

The tongue of salamanders is rough with papillæ, but that of frogs and toads has a smooth slimy surface. The chameleon has the tongue of a cylindrical form, covered on its surface with deep regular transverse furrows; and it is so constructed, as to be easily thrust out of the mouth, to collect the proper food of the animal.

The organs of smelling are imperfect, and consist chiefly of cavities opening in front of the snout, and communicating backward with the mouth, lined, like the nostrils of *mammalia*, with a pituitary membrane, for the ramification of the nerves. This membrane is in several species divided into several folds, supported by bony plates. Tortoises have three of these. The external nostrils are furnished with muscular fibres, by which they may be occasionally contracted and dilated. The nostrils are very close together in crocodiles, while in some of the other saurians, as the tupinambes, stelliones, and chameleons, they are more apart and lateral. In the tortoises, they are very small and close together; and they are also extremely small in salamanders. In short, from the small extent of the nasal cavities in reptiles, compared with those in quadrupeds, it appears that they are rather organs of respiration than of smelling.

These animals have, as we before hinted, no auricles or external ears, though their internal organs of hearing are sufficiently apparent. These consist of a tympanum, (except in the salamander,) and a labyrinth, with their attending bones and cavities. In turtles the membrane of the tympanum is cartilaginous, and covered externally by the integuments. The tympanum contains only a single little bone, and from it proceeds a Eustachian tube. In this order there are semicircular canals. The saurians, with the exception of the salamander, have the same parts, and several little bones, besides several soft stony substances in the vestibule. The crocodile is the only instance among reptiles, in which there is any appearance of external passage to the organ of hearing. The batracians, especially frogs, have a large membrane of the tympanum, level with the surface of the body. The tympanum contains two cartilaginous ossicles, and has a wide opening of the Eustachian tube next the throat. The vestibule contains rudiments of those soft stony substances just mentioned as occurring in the saurians. In the salamander, the vestibule contains one of these stony bodies, and the oval hole leading to the labyrinth is closed by cartilage. In general, the vestibule and membranous canals in these animals are much smaller than the bony or cartilaginous cavities in which they are contained.

There is, we believe, only one instance in reptiles where the eyes appear of little use. This is in that singular species, the *proteus*, in which the eyeballs are so covered with the integuments, as not to be visible till these have been removed.

In the tortoise tribes there is a bony ring, composed of thin plates at the anterior part of the sclerotic coat; and a similar structure occurs in frogs, chameleons, the guana, and some other saurians. The iris is variously coloured, but generally yellow, red, or brown. The pupil varies in figure. In the crocodile it resembles that of the cat, being vertically oblong; in frogs and geckos it is rhomboidal; and in tortoises, the chameleon, and common lizards, it is round. The crystalline lens resembles that of fishes in its spheroidal figure.

Besides the two eye-lids common to reptiles, and the superior classes of animals, the former have, like birds, a third, or nictitating membrane, which is vertical in tortoises and crocodiles, but horizontal in frogs. In the crocodile there is a bony substance in the upper eye-lid. In the common lizards, instead of eye-lids, there is a kind of circular veil extended before the eye, with a sphincter muscle, by which it may be closed.

There is considerable variety among reptiles with respect to the lachrymal gland. Turtles have it very large, and situated at the lateral or posterior angle. In the fresh water tortoises again, as well as in frogs and toads, there are two small, blackish glands.

Thus it appears that the eyes of reptiles are well adapted to perfect vision, and provided with ample defence against the too stimulating power of the rays of light. It is well known that many of them are very quick in perceiving their prey; and some species, as the green lizard and green frog, appear extremely fond of the brightest light. Some few, however, shun the day-light, and seek their prey chiefly by night, having for this purpose the power of contracting or dilating the pupil in a very considerable degree. It is said that the chameleon can move both eyes at once, in different directions, a circumstance scarcely noticed in any other animal.

The general phenomena respecting the nervous system of reptiles, and the influence of the brain on the other organic functions, cannot properly be considered till these functions shall have been examined. The remarkable tenacity of life in reptiles, their great reproductive power, and the phenomena of the torpid state which they undergo, all of which are more or less connected with the nervous system, must also be deferred till we have treated of the functions of circulation and respiration.

## CHAP. III.

### *Of Digestion in Reptiles.*

Digestion in reptiles is divisible into what we may call prehension, deglutition, and digestion, properly so called.* We shall here consider the organs and phenomena of these functions, in the order in which we have named them.

We have seen that the mouth of the *chelonians* is furnished with mandibles. These close over each other somewhat like the parts of a box, and frequently have their edges so deeply indented, as to have led to the mistake that some tortoises have teeth. The horny part of the mandibles is connected with the bony jaw, nearly in the same manner in which the hoof of the horse is united to the coffin bone. (See Mammalia and Veterinary Medicine.) In the upper jaw there is an intermaxillary bone. The lower jaw is articulated with the skull, by means of a bony eminence of the latter. The lower jaw only is moveable, and its motion consists of little more than opening and shutting the mouth. Many of this order possess great strength in the jaws.

The jaws, in many of the *Saurians*, especially in the crocodile tribe, are of very considerable length, and, in most instances, beset with numerous strong and sharp teeth. In most of the species, the lower jaw is moveable on the upper, in the usual manner; but in the crocodile there is a peculiarity in this articulation which merits particular notice, especially as it has been made a subject of dispute among naturalists from the earliest ages.

Herodotus was, we believe, the first to assert, that the upper jaw of the crocodile was moveable on the lower, which he supposed to be fixed. This opinion was followed by Aristotle and Pliny, and of course by the earlier modern naturalists, who copied from them. Of late, this general ancient opinion of the mobility of the upper jaw has been warmly called in question; and some of the French academicians believed they had demonstrated its absurdity. The more recent observations of M. Geoffroy, however, shew that the ancient supposition was wrong only so far as respects the lower jaw, as, in fact, both the jaws are moveable on each other. This peculiar articulation is well illustrated by Fig. 3. of Plate CCXCV. from which it appears, that the posterior extremities of the lateral branches of the upper jaw-bone are received into hollows in the lower, so as to admit of free and extensive motion. See *Annales du Muséum*, tom. ii. p. 39.

We are not, however, to suppose, that the upper jaw of the crocodile moves upon the cranium. The fact is, that the cranium is very small, and is so fixed within the branches of the upper jaw-bone, as to move along with this latter: the articulation of the two jaws being behind the cranium. None of the other *Saurians* have the maxillary articulation similar to that in the crocodile; but in many the length of the jaws, and consequently the opening of the mouth, is very considerable. The lower jaw in most of these animals is very complex, consisting of from eight to twelve pieces. In the *Batracian* order it is also complex, consisting generally of six pieces.

That part of the jaws which corresponds to the snout, has a very different degree of rotundity in the several orders of reptiles. It is most obtuse in the *Batracians;* less so, though still considerably rounded, in the *Chelonians;* while in the *Saurians*, the angle formed by the meeting of the branches of the jaw is generally very acute.

The muscles attached to the jaws are most powerful in the *Chelonians* and *Saurians*. In the former, the temporal muscles are the strongest; while in the latter, the digastric and the masseter appear most prominent. The force with which some turtles close the jaws is astonishing. It is even asserted, that when once closed with violence, it is impossible to open them; and that even when the head is cut off, the contraction of the muscles continues to act for many hours. A turtle has been known to tear asunder a large rope, by means of the indentations in its mandibles.

All the *Saurians* have teeth in both jaws, and in the *Guana* there are besides teeth set in the palate. All these teeth resemble the cutting and pointed teeth of the predacious quadrupeds, and seem entirely adapted to seizing and retaining prey. The number of teeth is seldom constant in the same species, and evidently depends on the age of the animal.

Among the *Batracians*, the frogs have teeth only in the upper jaw; salamanders have them in both; but toads have teeth in neither jaw. All these tribes, however, have them in the palate. The siren has teeth attached to the inner surface of the jaws.

*The organs of deglutition* in reptiles have a considerable variety in point of structure. We have already briefly noticed the tongue under the organs of sensation, but must here treat of that organ and its appendages at greater length.

In the *Chelonians*, the tongue is small and pyramidal, with the base turned backwards, and the point forwards. The *os hyoides*, or bone of the tongue, varies in different species. It is more or less cartilaginous.

The mechanism of the tongue in the Chameleon is extremely curious. The tongue itself is not larger than a goose quill, but is five or six inches long, growing broader towards its extremity, where it is covered with a glutinous matter. In the usual state of the animal, this organ lies within a sheath at the bottom of the mouth, and is so contracted as to appear not more than an inch in length; but when the animal is in search of prey, the tongue is, by peculiar muscles, darted out to the length we have de-

* Properly speaking there is no mastication in reptiles, and the jaws and teeth are used entirely for seizing and holding their prey. We have therefore taken the liberty of borrowing a word from the Latin, and have called this action *prehension*.

scribed, and catching the insects on which the chameleon feeds, by means of its glutinous secretion, is again withdrawn into the mouth.

In many of the reptiles, the tongue is composed chiefly of a thick glandular mass, formed of a great number of small pipes, united towards the base, and diverging towards the surface of the tongue. In fact, in these cases the tongue forms a salivary gland, and the same saliva prepared in it is poured out by numerous orifices along the sides of the organ. This is particularly the case in the *Chelonians*, and many of the *Saurians*; and a similar structure, though to a less extent, prevails in the *Batracians*.

In those reptiles that have a scaly tongue, there are two oblong sub-maxillary glands.

What is called the *pharynx*, or swallow, is in reptiles not easily distinguished from the gullet, to which it forms the opening, its diameter being nearly the same with that of the gullet.

The gullet in reptiles is nearly of equal diameter through its whole length, and this diameter is greater in proportion to the stomach than in quadrupeds. In the *Chelonians*, its internal surface is sometimes beset with hard long conical papillæ, with their points directed backwards, apparently for the purpose of preventing the return of the food from the stomach. In this order, swallowing is also facilitated by the action of muscles placed along the neck, and inserted into the gullet, as well as by the bone of the tongue and its muscles. The same mechanism is evident in the *Batracians*, especially in the frogs and toads; and in all this class there are usually in the gullet numerous longitudinal folds, which, by admitting a considerable degree of expansion in the tube, as the food passes through it, greatly facilitate deglutition.

The *stomach* of reptiles is of very various figure and dimensions, in the different orders, tribes, and species. In the *Chelonians* this organ appears as if doubled back upon itself; and that portion which is opposite the principal curvature, has its sides thicker than the rest, and is internally plated with longitudinal folds. The insertion of the gullet in these animals is distinguished by the sudden dilatation formed by the stomach. Among the *Saurians*, the crocodile has the stomach of a globular figure, divided, however, into two unequal portions. See Plate CCXCV. fig. 4. The stomach of the *Guana* is oval, and very long, without curvature, and not easily distinguished from the gullet, fig. 5. In the Tupinambis, the stomach forms a long tube, bent nearly into a circle, fig. 6. The stomach of the Chameleon begins by an inflated portion, then takes the form of a long cylinder, and bends back upon itself, fig. 7. In the Dragon, this organ is strait, and has nearly the shape of a pear. In the *Batracians*, the form of the stomach resembles that in tortoises, but is proportionally more dilated. In *Salamanders*, it is long, not much expanded, and strait, except near its farthest extremity.

The intestinal canal of reptiles is not easily to be divided into small and large by any particular appendage, like the *cæcum* of quadrupeds; though the distinction in point of diameter, holds in most species. All the *Chelonians*, most of the *Saurians*, and all the *Batracians* except the *Siren*, have a long small intestine inserted into one extremity of a short great gut, into which it is usually prolonged, so as to form a valve. In the *Iguana* only, is there any thing like a *cæcum*.

The intestines of reptiles in general are very short.

In the *Chelonians*, what may be called the small intestine is largest at its juncture with the stomach, and gradually diminishes in diameter till it terminates in the great intestine, where its diameter is only about one-fourth of that of the latter. The coats of the intestines in this order are thicker than in those of most other reptiles. See Fig. 8.

In the *nilotic crocodile*, the small intestine is divided into two portions, of which one is of greater diameter, and has thinner coats than the other. This intestine is remarkable for a thin layer of a pulpy glandular substance, between the muscular and the villous coats. The large intestine of the *nilotic crocodile* is cylindrical; but in another species, the *gavial*, it is pear-shaped, fig. 9. In the *lizard tribe*, the large intestine is cylindrical, and of much greater diameter than the rest of the canal, fig. 10. In the *chameleon*, the whole intestinal canal is nearly of equal diameter, except at one part, where it forms a sort of valve. In the *dragon*, the intestines make about two circumvolutions and a half, before terminating in the anus. In most of the *smaller saurians* the coats of the intestines are thin and transparent.

The most remarkable differences in the intestinal canal of the *Batracians*, are those which take place in the same species at different periods of its existence. In the *tadpole*, or young animal, the intestines are very long, small, and nearly of equal diameter, without any valvular distinction, and have numerous circumvolutions. In the perfect animal, the whole intestinal canal is much shorter, the distinction into small and large intestines very evident, and the circumvolutions much fewer. In frogs, the large intestine is cylindrical; in toads, it is more or less conical. The difference of diameter between the large and small intestines is most evident in *salamanders*, whereas in the *siren* this distinction is scarcely to be noticed. See Fig. 11.

The food of most reptiles consists of worms, insects, and other small animals, which they swallow whole. Of course the process of digestion takes place almost entirely in the stomach, where the gastric juice is evidently possessed of considerable solvent power. Some of the Chelonian order, indeed, feed partly on sea-plants, thence called turtle grass, which they bite off with their horny mandibles, and swallow whole.

Many of these animals are extremely voracious, and will gorge themselves with living worms or insects, till they become nearly incapable of motion, and till the animals they have swallowed crawl again out of their mouths.

The process of *deglutition*, in most reptiles, is effected by repeated contractions and dilatations of the throat and gullet, which are very evident to an observer. It is supposed by some physiologists, that part of the prey in some species undergoes a degree of solution in the gullet; but this seems to us not very probable.

Though the solvent power of the gastric juice in reptiles is undoubted, its action is sometimes very slow, especially on living animals, these having been found undissolved, and sometimes even still alive, at the end of several days.

Notwithstanding the voracity of some reptiles, it is astonishing how long almost all these tribes can support the want of food. Turtles and tortoises, even when not in a torpid state, have lived for 10, or even 18 months, without taking any kind of food. Newts have lived for two months, a chameleon for eight, salamanders for an equal period, protei for two years, and toads for a much longer time, under the most perfect abstinence. It is most extraordinary, and the circumstance forms a strange anomaly in animal physiology, that although these reptiles gradually lose their vitality from the want of food, they do not lose weight in proportion, and in some instances suffer no sensible diminution or flaccidity of muscle.

## CHAP. IV.

### *Of Circulation and Absorption in Reptiles.*

There are several peculiarities in the circulation of reptiles, and the organs vary considerably in the different orders. In some they are similar to those of the higher classes of animals, except that the principal cavities of the heart communicate more or less freely with each other; in others, the circulating system is entirely different from that of *Mammalia*, and much more simple.

In the Chelonian tribes, the heart is very broad in proportion to its length, but differs in figure in the two genera, being nearly hemispherical in the proper *Cheloniæ*, and of an oblong square form in the *Testudines*. In both it has two auricles, and a ventricle divided into compartments. It is situated below the lungs, and between the lobes of the liver. The auricles are very large, forming each about one-third of the whole heart, and spread wide at the base of the ventricle. Their sides are thin, and their cavities do not communicate. The ventricle is strong and fleshy; and its cavity, which is naturally small, is still more diminished by numerous fleshy bundles that proceed from its sides, and are separated from each other in such a manner as to leave spaces between them. The auricles communicate with the ventricle by large apertures, guarded by membranous valves; and on each side of the ventricle are orifices, also furnished with valves, that lead to the great arterial trunks. The pericardium is large, and closely attached to the contiguous membrane, as to the diaphragm in quadrupeds.

In the *Saurians*, the heart is also provided with two auricles; and in one tribe, the crocodiles, is even more complicated than that of the first order. It is in the crocodiles, indeed, that its structure has been most accurately examined, and to this tribe we shall here confine ourselves.

The heart of the crocodile is situated partly between the lungs, and partly between the lobes of the liver. Its auricles are proportionally less than in the *Chelonians*, but their sides are thicker, and strengthened by fleshy bundles, diverging in various directions. The ventricle is of an oval form, and has very thick sides. Its cavity is divided into three compartments, communicating with each other by numerous orifices. One of these is below, and towards the right, and communicates with the right auricle by a large opening, contracted by two valves that direct the blood through its upper part. On the left side of this cavity is the passage to a large artery on the left, that distributes blood to the sacral or hind parts of the body; and behind this an orifice leads to the smallest of the three compartments, situated at the middle of the base of the heart; and from this arises the common trunk of the pulmonary arteries. (See Plate CCXCV. Figs. 12, 13, 14.)

Hence the blood that is poured by the right auricle into the compartment on that side flows chiefly in two directions; 1*st*, Into what may be called the *right systemic* compartment of the ventricle, which throws it into the left *sacral aorta;* 2*dly*, Into the *pulmonic* compartment, which impels it into the pulmonary artery, though some of it probably oozes into the left systemic compartment. The left auricle receives the blood from the pulmonary veins, and pours it into the left compartment; and from this latter it is thrown into the left systemic artery, the carotids, and axillary arteries.

The *Batracian* order have a heart extremely simple, consisting of a single auricle, and a single undivided ventricle, of a conical form, from which arises one arterial trunk, that by its branches transmits the blood to all parts of the body.

We cannot here enter into an examination of the number and course of the principal blood-vessels in the reptile tribes; but must refer the reader to Cuvier's *Anatomie Comparée*, Leçon xxv. Art. 3. vol. iv. where they are minutely described.

There is not that well marked distinction between the arterial and venous blood in reptiles, which is found in *mammalia cetacea*, and birds; but in some species there is a manifest difference, as Caldesi has observed in tortoises. It is said that reptiles which have fasted long, have the blood of a paler colour than the same species regularly fed.

The absolute quantity of blood in the circulating system of reptiles is proportionally much smaller than in *mammalia* and birds; hence their muscles are whiter, and their lungs of a paler colour, than in those classes. The circulation in these animals, though not so complicated as in the higher classes of animals, is yet a perfect circulation; and, as in the higher classes, though not in the same degree, the blood takes a double course, some of it passing through the lungs before it be distributed to the rest of the body. We shall see, in the succeeding chapter, that although the lungs of reptiles are larger in proportion than those of *mammalia* and birds, they are less vascular, and therefore contain a smaller quantity of blood. It is this imperfection of what has been called the lesser circulation, and the slight difference between the *systemic* and *pulmonic* blood, that lay the foundation for some of the most remarkable circumstances in the physiology of these animals. We are now prepared to consider two of these circumstances—the remarkable faculty of reproduction of parts that have been mutilated or destroyed, and the great tenacity of life, at which we have already hinted.

It is chiefly in the lizard tribe and salamander, that experiments and observations on the reproduction of parts have been made; but it is reasonable, from analogy, to infer, that similar phenomena may take place in other tribes. The lizards are peculiarly liable, from their smallness and the numerous enemies to which they are exposed, to partial injury or destruction of their members. This is particularly the case with respect to the tail, which is long and slender, and in many species so brittle as to break short on being handled. In these cases it has been repeatedly observed, that the part lost has been in no long time reproduced, generally similar to the original, but sometimes a double tail has appeared.

The reproduction of lost parts in reptiles, has been made the subject of numerous and satisfactory experiments, especially by Spallanzani, Bonnet, and Blumenbach. From these it appears, that when part of either extremity, or of the tail, is cut off, from two species of lizard, the *lacerta agilis*, and *lacustris*, or water newt, the wound is followed, for two or three minutes, by an effusion of blood, after which the stump gradually heals, and in the course of a few days the rudiments of a new limb or tail begin to make their appearance; that these rudiments are gradually developed, till in a few months, or sometimes little more than a year, there is formed a perfect member, similar in size and proportions to that which had been cut off, only retaining for some time a delicacy of structure and transparency of appearance, not found in the original organ. It is further proved, that these regenerated parts may be again repeatedly removed and reproduced. The most surprising of these experiments, however, are those of Bonnet and Blumenbach, on the reproduction of the whole eye in the water newt. These have taught us, that when the eye of that animal is dissected from the orbit, so as to leave about a fifth of the membranes in contact with the optic nerve, the vacant orbit is first closed by the eye-lids, and gradually the vacuity is filled up with a growth of new parts, which in about a year acquire the perfect structure of an eye, with its investing membranes, contained humours, transparent cornea, and coloured iris.

We have already remarked the great power of abstinence possessed by reptiles, and have now to notice some other unfavourable circumstances, under which they continue to live and perform most of their functions.

Most reptiles possess the faculty of resisting extremes of heat and cold, and the effect of chemical agents, better than other animals. Though nobody now believes the ridiculous stories of salamanders living in the fire, it is still a curious fact, that lizards and alligators live with ease and apparent satisfaction in the waters of hot springs, heated to a degree very considerably higher than the hottest temperature of the torrid zone. Frogs and newts are often exposed to a degree of cold far below the freezing point, while in a state of torpidity, and they have even been known to remain imbedded in a block of ice for many hours, without having their vitality extinguished. Some of these animals, that have been put alive into spirit of wine, for the purpose of preserving them as specimens, have remained alive for several hours; and other instances are recorded of their existing for a considerable time in the exhausted receiver of an air-pump. Frogs and water-lizards have lived, and moved with agility, many hours after having been deprived of their hearts; and Redi, by a curious but cruel experiment, proved that a land-tortoise, after having the cavity of the skull laid open, and the brain dissected out, walked away with apparent unconcern; and, except that its eyes closed, and never afterwards opened, it appeared for several months to enjoy life, and exercise its functions nearly as before the loss of the brain. Frogs, which were subjected to a similar experiment by Spallanzani, lived for five days. Nay, a turtle has been known to live and move its limbs for thirteen days after its head had been cut off.

Not only is the body in general of reptiles thus tenacious of life, but the parts and organs that have been cut off shew signs of vitality and irritability, for hours and even days together. The tails of water newts have exhited very lively motions for more than ten hours; the heart of a frog has continued to palpitate, when irritated, for several hours after being taken from the body: the head of a turtle has not only opened and closed its jaws, but has closed upon a stick with considerable force, two days after having been amputated.

The *absorbent system* of reptiles has been very little examined, and the investigation has scarcely extended beyond the Chelonian order. We find that the thoracic duct of turtles is double, and that the mesentery in these animals abounds with lacteals. Numerous lymphatics are seen running in a longitudinal direction, both on the superficial and central coats of the intestines; but it is not certain that these animals possess lymphatic glands.

If we may judge from the little waste that takes place in the body of reptiles during a long abstinence, and while in the torpid state, it would seem that their absorbent system possesses less activity than that of most other animals.

## CHAP. V.

### *Of Respiration and Voice in Reptiles.*

The lungs of reptiles are proportionally much larger than those of quadrupeds and birds, and they are also of a much looser texture; their structure is most complicated in the Chelonian order, in which they are of a uniform texture, but the air vesicles are very large. In the *Saurian* order, the lungs form two large vesicular bags, one on each side the heart, and have their internal substance divided by membranous plates into numerous polygonal cells, which are again subdivided into smaller. All the *Batracian* order have lungs, which resemble those of most of the Saurians in largeness and simplicity; but in the tadpole state they have also gills, which disappear in the perfect animal, except in two tribes, in which they are permanent.

In all, the lungs float loose with the other viscera in the same cavity, and appear to have no innate contractile power.

The windpipe, except in one or two instances, divides into branches or *bronchi*, before it reaches the lungs; but this division takes place nearer the head in some tribes than in others. In the Chelonians, it commences very early, while in the crocodile the trachea continues undivided for a considerable extent. In general, however, the bronchi are very short, and in most instances they terminate abruptly in the lungs.

The extent of the lungs is greatest in the Chelonians, in whom they reach along the whole length of the back. The lungs of reptiles are supplied with blood by the pulmonary arteries, there being in general no bronchial vessels.

The gills or branchiæ of tadpoles, and of the proteus and siren, resemble the gills of fishes in their general structure, but are not, like them, inclosed within a particular covering, but hang loose and floating on each side of the neck. They form three or four rows of small tufts or fringes, supported by small cartilaginous arches; and these arches are articulated on one side behind the cranium, while on the other they are united to a bone resembling the os hyoides. They have between the rows intervals, by which the water in which the animal floats is freely admitted to the mouth. The branches of the siren consist of three tufts.

The spongy texture, and little vascularity of the lungs in reptiles, enable them to take in a greater quantity of air than other animals at a single inspiration, and this capacity appears to be increased by the expansive power of the air cells. It is remarkable, that reptiles not only receive air into the lungs in the ordinary way of inspiration, but swallow it by the mouth, in which action they are assisted by the muscles of the throat. In fact, it is only by deglutition that the Chelonians inspire, and in expiration the animals of this order employ chiefly two pairs of muscles, situated in two layers near the tail, between the shield and breast plate. In the Saurians, the mechanism of respiration is executed chiefly by the abdominal muscles, and by those which move the ribs.

From the large quantity of air which reptiles can inspire at once, there is the less occasion for frequent respiration; and, accordingly, in these animals, the breathing is remarkably slow. It is least slow in the Chelonian tribes, and it appears to be slowest when the animals are asleep. What is most remarkable, however, in the respiration of reptiles, is the power they possess of suspending respiration. Tortoises have been known to live more than a month with their jaws closely tied, and their nostrils stopped with wax; and there seems little reason to doubt the remarkable instances that are on record, of toads being found alive in the trunks of trees and blocks of solid stone, where the function of respiration must have been suspended for years together. It also appears that reptiles can live for a longer time uninjured in deoxygenated or impure air than other animals; a circumstance that is explained on similar principles. This continued vitality in vitiated air has its limits however; for it is found, that when these animals are confined in atmospheric air, they cease to exist when the oxygenous portion is expended.

The changes produced on atmospheric air by the respiration of reptiles, are similar to those produced by the breathing of other animals, viz. the consumption of oxygen and formation of carbonic acid. On this subject we may refer our readers to Mr Ellis's *Inquiry into the changes produced on Atmospheric Air*, published in 1807, and *Further Inquiry* in 1811, in which the experiments and observations made by the ingenious author, and collected by him from former writers, are fully and satisfactorily detailed.

Intimately connected with the function of respiration, is the vital heat of animals. We have already seen that this in reptiles is very low. It appears, however, that, under the ordinary temperature of the atmosphere, the heat of these animals is generally a few degrees above that of the surrounding medium; and while life continues, they have the power of preserving a moderate temperature, and of resisting, to a certain degree, considerably inferior indeed to man and quadrupeds, the extremes of either heat or cold. See Chap. IV.

Almost all reptiles utter sounds more or less loud; the salamander and the green lizard being almost the only known exceptions; and it is even not certain whether the former should be entirely excluded. Turtles and tortoises hiss or sigh; crocodiles low or roar, sometimes in so loud a tone as to resemble distant thunder, while the young of these animals are said to make a noise like a cat, (but whether *mewing* or *purring* we are not told,) and to utter piercing cries if attacked, when first extruded from the egg. Iguanas make a sort of whistling sound as they run along the trees, and the croaking of frogs and toads is sufficiently known.

The organs of voice in these animals are very simple, consisting of a single *larynx*, without *epiglottis*, but including ligamentous chords of the *glottis*, moved by appropriate muscles. In some species of frogs, especially the males, there are also membranous bags connected with the glottis, or pouches in the cheeks, which, when inflated, serve to increase or modify the sound.

## CHAP. VI.

### *Of Secretion and Excretion in Reptiles.*

The most important of the secreting organs, which we are to notice in reptiles, are the liver, pancreas, spleen, and urinary organs.

The liver of these animals is always large; and in some instances, as in the salamander, its proportional magnitude is very considerable. In the Chelonians it is divided into two rounded irregular lobes, the one occupying the right hypochondrium, and the other connected to the stomach at its small curvature. It is also divided into two lobes in the crocodile and the chameleon; but in the other Saurians, it forms only one lobe, differing in size and figure in the several tribes. In all the Batracians, except the salamander, the liver is composed of two lobes.

All reptiles have a gall bladder, which is more intimately connected with the liver, but is proportionally smaller than in quadrupeds and birds. In the Chelonians, it is almost wholly concealed in the right lobe of the liver, and is found in a similar situation in crocodiles. There are generally two ducts leading to the intestines; one from the liver, the hepatic duct; and the other, the cystic, from the gall-bladder; and these, in most instances, run separate from each other.

The position and size of the pancreas are very various. In most of the Chelonians it is triangular, and generally entire. In the crocodile it is divided into lobes. In some of the Batracians, as the frog, it is lodged in the arch of the stomach towards the sternal part of the body; in others, as the salamander, it is situated in the first curve of the intestines. The pancreatic duct is commonly single, but in some instances, as in the Nilotic crocodile, it is double.

The spleen exists in all reptiles, but its structure, form, and situation, in these animals, has been very imperfectly investigated. In the Chelonians, it is shaped like the kidney; in the Saurians, it is elongated; in most of the Batracians, as frogs and toads, it is small and spherical, and in the former tribe is situated in the mesentery; while in salamanders it is of an oblong form.

All reptiles appear to have kidneys; but the structure of these organs is extremely simple and uniform, as they have no distinction of cortical and medullary substance, and no parts corresponding to the *infundibula* and *pelvis* in mammalia. In figure and situation, however, they vary in the several orders. In the Chelonians they are short and thick, and lie far back in the cavity of the abdomen. In the Saurians they are of an oval form, more or less flattened and elongated, and in general they lie far back under the sacrum, or near the tail. It is uncertain whether their form varies with age in all these animals; but it appears that in young crocodiles they are entire, while in full grown individuals of the same tribe they are divided into several lobes. In the Batracians they are situated pretty far forward and very near each other, and resemble those of the Saurians in form.

All the reptile tribes have not an urinary bladder. It is found in the Chelonians, in whom it is very large, and is more or less divided into two portions. Of the Saurians, only the tupinambis, iguanas, stellios, chameleons, and dragons, have an urinary bladder. It is found in the Batracians, in some of whom it consists of two membranous bags, while in others it is single.

In reptiles there is a common receptacle or passage for the urine and *fæces*, called *cloaca*; and in those tribes that have no urinary bladder, the ureters, or pipes from the kidneys, open immediately into this receptacle.

Several secretions of a peculiar nature take place in reptiles. Thus, in the crocodile, there is a gland situated on each side of the lower jaw, just beneath the skin, having a duct opening externally, and secreting a substance that smells like musk; while glands of a similar nature are found in the cayman, near the anus. In several of these animals, as in toads and salamanders, an acrid fluid exudes through numerous pores of the skin when they are irritated. This fluid is not, however, poisonous, as has been supposed; but among the Saurians, the geckos secrete from between their toes a matter, which is really of a venomous nature. See Gecko in the subsequent Part.

## CHAP. VII.

### *Of Integumation in Reptiles.*

A considerable variety is found among the reptiles with respect to their integuments; and as these varieties constitute many of the generic and specific characters, it is necessary to examine them with some minuteness.

In all these animals there is the usual distinction of cuticle, true skin, and *rete mucosum*. The structure of the skin and *rete mucosum* differs but little from that of other animals, except in the frog and toad, where there is this peculiarity, that the skin adheres to the parts beneath only at a few points, so that it forms a sort of loose bag about the animal, susceptible of occasional inflation. The cuticle is extremely various in the different orders and tribes. In the Chelonians, though only the head, tail, and extremities, appear to be covered with skin, yet in reality the whole body within the shell is enveloped with a thin transparent cuticle, capable of being detached in plates. In most of these animals, the cuticle, when exposed, is covered with scales of a horny texture, and differing very much in number, situation, and figure. A thin membrane resembling cuticle, also covers the shell of the Chelonians; and in several species, the upper shell, or shield, is covered with a dense and strong membrane resembling leather or parchment. Among the Saurians there is first a cuticle enveloping the true skin, then scales, plates, or tubercles, and over these again another cuticle, as in the Chelonians. In the crocodiles and *Dracæna*, there are strong and broad plates differently shaped and arranged, as we shall see hereafter; in the tupinambes, the scales are disposed in circular rows or transverse bands; in the basilisks, they are diffused over the whole body, while in the lizards again, they are arranged in transverse bands. The Batracians have the epidermis smooth, and in general slimy.

The Saurians have generally very strong and numerous subcutaneous muscles, especially in the tail; and in most cases, there is an intimate connection or adhesion between these muscles and the skin.

We have already seen that the Chelonians are covered, both on the upper and lower parts of the body, with a strong and hard shell, of which the upper part may be termed the shield, and the lower the breast plate. Each of these is divided into a considerable number of separate plates, united together by their edges, sometimes in a smooth and even manner, at others overlapping each other. A row of these plates lies along the middle of the back over the vertebræ, and these are surrounded on each side by several others, which, together with the vertebral plates, constitute what is called the *disc*. The other plates of the shield, lying between the disc and the breast plate, are called *marginal*, and are generally from twenty-one to twenty-five in number. They are of a more irregular figure than those of the disc, and generally of an oblong form. The shield is more or less convex. The shield and breast plate are united only at their sides, leaving a space at the fore and back parts for the head, tail, and extremities. This shelly covering, in general, resembles the hoofs of quadrupeds in its texture, though in some instances, as in what is called tortoise-shell, it is purer and more transparent than the finest horn.

The Saurians and Batracians occasionally change the cuticle, throwing off the old, and acquiring a new one. This is particularly the case while they are young, and after leaving their winter quarters. In these animals, the change is not made at once, as in serpents, (see Ophiology,) but the cuticle is detached in scales or plates, till the whole is thrown off.

## CHAP. VIII.

### *Of Generation in Reptiles.*

There is no part of the economy of reptiles more curious, none more interesting to the naturalist, than that function by which these animals generate their like. The differences, with respect both to organs and pnenomena, which are found in this class, admirably illustrate the observation of a celebrated naturalist, that a systematic arrangement of animals, as well as plants, might be composed merely from a comparison of their generative organs.

A difference of sexes prevails in all reptiles, and the distinction of male and female organs is in most instances very manifest. There is one part of the structure, however, found in both sexes. The *cloaca*, which has been already noticed as forming the common outlet for the urine and fæces, also forms, as in birds, the common receptacle of the external organs, and the outlet for the ova.

All male reptiles have *testes*, but these organs differ in form and situation. In the Chelonians, they lie within the abdominal cavity, (as is the case in all these animals,) contiguous to the kidneys, and united to their inferior or sacral surface. In the Saurians, they lie in front, or on the sternal side of the kidneys, on each side of the vertebral column; and in the Batracians they are situated immediately below the anterior surface of those organs. In the first order, the *testes* are composed of large vascular bundles, disposed in various directions; and the *epididymis* is formed in the usual way, by the convolutions of the vessels, particularly of the seminal duct, or *vas deferens*. It is not certain whether these animals have seminal vesicles. The *testes* of the crocodile are long and narrow, and communicate with two organs that are supposed by some anatomists to be seminal vesicles; and if so, form the only instance of these organs among the reptile tribe. In salamanders, each of the *testes* is divided into two spherical bodies, placed one before the other: and their texture consists, as in all the Batracians, of an agglomeration of small whitish granular bodies, interspersed with blood-vessels.

The *penis* is single in all the Chelonians, and in most of the Saurians. The Batracians have no organ of this kind; but, in some of that order, its place appears to be supplied by a small *papilla* within the *cloaca*. This organ is most remarkable in the Chelonians, in some of whom it is of very considerable length. It is cylindrical, terminates in a point, and has a deep furrow along the whole extent of its upper surface. It is furnished with two retractor muscles, by which it is withdrawn within the cloaca, where it usually lies concealed, and from which it is thrust out in preparing for copulation. In the Saurians, this organ is short, cylindrical, and beset with numerous spiny processes, resembling the bristles of the hedgehog. In the usual state, it is drawn up under the skin of the tail, and, when erected, appears externally at the slit of the *cloaca*.

We must here notice a peculiarity of structure in the males of those reptiles which do not immediately copulate with the female. There are found in these males, during the copulating season, hard brown or blackish *papillæ* or tubercles, attached to the thumb and palm of the fore feet, which assist in grasping the female. These tubercles are found chiefly in the frog and toad. Salamanders have, during the same season, a crest with divided edge upon the back and tail, which afterwards disappears.

The female reptiles have ovaries, and most of them a *uterus*, or an expansion of the oviducts, which answers a similar purpose. The ovaries of the Chelonians resemble those of birds, (see Ornithology.) They are two in number, and have each a duct opening into a *uterus*. The *uteri* are thick and fleshy, and have openings by which they communicate with the *cloaca*. The ovaries of the Saurians and Batracians are much alike; but the former contain fewer eggs, and have larger and shorter oviducts. Those of frogs lie below the liver.

A curious structure prevails in the female of the Surinam toad, or *Bufo dorsiger*. The skin of the back in this animal is hollowed out into a great number of cells, in which the ova, after being extruded by the female, and fecundated by the male, are placed by the latter; and here they remain enveloped in the skin, which contracts round them till they are hatched, and ready for enjoying a separate existence.

Only the Chelonians and Saurians enter into actual copulation, and this act is different in the two orders. It is not certainly known in what manner the male and female turtles and tortoises perform this act. It is supposed, and even asserted by some, that they unite breast plate to breast plate, while others affirm, that the union takes place in the manner of quadrupeds. We are not disposed to enter into the minutiæ of these reptilian amours, as we do not think them calculated for a work addressed to general readers. Those who wish to gratify their curiosity on this part of comparative physiology, may consult the dissertations of Spallanzani, and the works of Reësel, Swammerdam, and Daudin, already mentioned in our historical notices.

The season of copulation commences early in spring, or as soon as the animals are roused from their winter state of torpor, and seems to return only once a year: it continues for a longer or shorter time in different orders and tribes, generally longest among the frogs and toads.

All reptiles are properly oviparous, though in one instance, the salamander, the ova are hatched in the oviduct. In most of the tribes, the eggs, though numerous, are laid distinct from each other; and, in that case, they are enveloped either by a calcareous shell, or a membrane resembling parchment. Frogs and toads, however, lay eggs that are connected together in a kind of bunch, and are of a gelatinous consistence, each egg containing in its centre a dark spot, which is the rudiment of the future young, (see Plate CCXCV. Fig. 15.) These connected eggs are extruded gradually by the female, and each is fecundated by the male as it escapes from the cloaca. What may be considered as perfect eggs, which are those of the Chelonians and Saurians, are very similar to those of birds, except that the transparent fluid, which corresponds to the *albumen* in the latter, does not coagulate by heat. The eggs of the Chelonians, and, according to some authors, those of the crocodile, afford good and wholesome nourishment to man.

We have said, that the young of the Batracians undergo a *metamorphosis;* and this is not the least interesting part in the physiology of generation in these animals. M. Reësel, in his *Historia Ranarum Nostratium*, has given a minute account, illustrated by figures, of the progress of the common frog, from the time when the egg is first fecundated to the completion of the perfect animal. We shall here present our readers with an abstract of this account.

Two days after the ovum is excluded, the central spot is somewhat enlarged, but still spherical, and is enveloped by an immediate albuminous covering, very distinct from the exterior mucilage. In four days, the central germ has assumed the shape of a kidney bean, and its albuminous covering is enlarged. In five days, the kidney-shaped embryo has changed its form to that of a half crescent, though still scarcely increased in size; but the following day it has become longer, thicker, and straighter, and the distinction between the outer and inner mucilage is no longer visible. The head, eyes, and mouth are also now obscurely visible, and there is some appearance of a tail. By the seventh day, the size of the tadpole is increased, and the distinction of head and tail more evident; and there are also visible the rudiments of the fore feet, and of the gills. It has now quitted the egg. At the end of nine days, the head and body are enlarged, and the tail considerably lengthened. Soon after this, the *branchiæ* are so much increased as to be distinctly observed; but, about the twentieth day, these appendages are withdrawn below the skin, as no longer necessary; and about four days after, the fore legs, which till now had been almost entirely concealed below the skin, appear externally. The body of the tadpole is still transparent, and its long intestines are seen extending from head to tail, (see Plate CCXCV. Fig. 16.) In a few days after this, the tail gradually disappears; the hind legs are developed; and in about two months from the first exclusion of the ovum, the animal becomes a perfect frog.

The metamorphosis of all the Batracians does not proceed exactly in the manner above described. In particular, the tadpole of the *Rana paradoxa* undergoes such remarkable changes, as to have been mistaken for an animal of a very different class. These will be noticed in a subsequent part of this article. The young of salamanders also differ from the tadpoles of frogs, and have been denominated *larvæ.* They remain four months in the tadpole state.

## CHAP. IX.

### *On Hybernation in Reptiles.*

Having, in the preceding chapters, described the organization of Reptiles, and given a comprehensive view of their organic functions, we have only to consider the phenomena that take place in these animals at that season when they begin to lose sense and motion, and sink into a state of torpor.

If we except the insect tribes, there are no animals to whom heat appears more necessary for enabling them to exercise their functions with vigour and activity, than reptiles. We shall find presently, that by far the greater number of the species are natives of the torrid zone, and indeed the few which inhabit these colder regions are comparatively lifeless and inactive. The heat of the sun seems to increase not only their vivacity and agility, but their sensibility. Cold produces the contrary effects; and when this takes place in any considerable degree, they become listless and inactive, and would probably perish, if they did not seek for refuge in some situation where they are in some measure sheltered from the cold in its extreme degree. Accordingly, we find that, on the approach of winter, these animals betake themselves to some retreat corresponding to their natural situation. Turtles and fresh water tortoises imbed themselves in the muddy or the sandy bottoms of lakes and rivers, while land tortoises make an excavation in the earth, and there find a temporary grave. Crocodiles, and those other Saurians which resemble them in their usual habitation, find retreats in sandbanks; while others, especially the Batracians, retire to crevices of walls, cavities of stones, clefts of trees, and caverns of mountains; while a few seek a precarious continuance of warmth by creeping into dunghills. In these retreats, where they can no longer find their accustomed prey, they gradually sink into a state of insensibility, and appear in a profound sleep, scarcely to be distinguished from actual death.

As this torpidity approaches, their circulation becomes languid, their respiration is extremely slow, their appetite for food appears to cease, and their temperature sinks below its natural standard. So complete is their want of sensation, that they may be cut, torn, and in some cases broken to pieces, without expressing the least degree of pain, or showing any signs of motion.

In this state they continue generally during the whole winter; and, as the genial heat of the spring returns, or in those climates where the changes of season are not so remarkable, when the analogous revolution of the season takes place, the animal begins to shew signs of returning life, gradually recovers sense and motion, its heart beats with a gradually increased velocity, its respiration becomes more frequent and regular, its temperature increases, it quits its retreat, resumes its ordinary functions, searches after prey, and seeks a mate.

It is remarkable that this hybernation of reptiles is not confined to those species which inhabit a cold or temperate region, but seems to extend even to the hotter climates of Barbary, Egypt, and South America. It is also worthy of remark, that this continued state of torpor, unlike the winter sleep of bears, marmots, and other hybernating quadrupeds, does not produce any very evident emaciation or loss of weight in the torpid animal. Land tortoises have been repeatedly weighed just before retiring to their winter quarters, and after emerging from them, and were found in some cases not to have lost above two ounces.

It is found that when some of these animals, as tortoises, in a state of domestication, are taken from their winter retreat, and exposed to a more elevated temperature, they recover, in some degree, their sense and motion, though they scarcely ever take food during this period. We have known a land tortoise, kept in a room where there was almost a constant fire, lie for several weeks together in the box that formed its retreat, without making any attempt to come out, and though when taken from the box, it opened its eyes, moved its head, and sometimes walked a little, it could not be prevailed upon to eat till its usual period of hybernation was completed. The person with whom it lived, with officious kindness, would sometimes force a little broth or soup into its mouth; but the animal never showed any desire to eat of its own accord. See Hybernation.

## Part II. CLASSIFICATION AND NATURAL HISTORY OF THE SPECIES.

### ORDER I. CHELONIAN REPTILES.

We have seen that most of this order, comprehending the animals called turtles and tortoises, are enclosed within a horny covering, consisting of two parts, one covering the back, and usually called the *shield;* the other supplying the place of a sternum, and called the *breastplate.* Each of these is composed of numerous *plates;* those of the shield being most numerous, and divided into those of the *disc*, or middle part, and those of the margin. The plates of the *disc* are generally thirteen in number; and those which are ranged along the back from head to tail, are denominated *vertebral* plates. The plates of the margin vary in the different species from 21 to 25. There are several terms applicable to these plates, which occur in the following characters, and therefore require explanation here. When the plates rise in a ridge in the middle, they are said to be *carinated;* when they have depressions in the contrary direction, they are *furrowed;* when they are uniformly highest in the centre, they are *convex*, or *subconvex*, according to the degree of elevation; when they lie upon each other like tiles or slates upon a roof, they are *imbricated;* when they are notched about the edge like the teeth of a saw, they are *serrated.*

The shield and breast plate of these animals are more or less firmly united together at the edges, leaving openings for the head, legs, and tail. Some species have the power of withdrawing all these parts within the shell, where they lie as if shut up in a box, safe from the attacks of almost every animal but man.

The legs of these animals are very short, but so strong, that one of the larger turtles has been known to walk with apparent ease, while several men stood on its back. In their motions they are slow and awkward, and, with very few exceptions, they are inoffensive, and submit, without resistance, to the most cruel treatment. They pass the winter in a torpid state.

### Genus I. Chelonia. TURTLES.

The feet flattened, so as to resemble the broad part of an oar; the toes of unequal length, united together so as to form a broad expanded surface, with flat nails inserted into its margin.

The *Cheloniæ* comprise the largest species of this order; some having been found that weighed seven or eight hundred pounds. They are inhabitants of the ocean, and feed partly on fuci or sea-weeds, and partly on the mollusca and other small sea animals that harbour among these submarine plants. The eggs of all the species, and the flesh of most of them, afford a delicious repast even to the epicure.

Of this genus only six species are distinctly marked by naturalists, though it is understood that Schoepff, the Prussian naturalist, was acquainted with eight. These six species may be thus distinguished.

Species 1. *Chelonia mydas.* Green turtle. Plates of the shield neither imbricated nor carinated, in number thirty; four feet, furnished with two nails. See Plate CCXCVI. Fig. 1.

*La tortue Franche.* Daudin, *Hist. Nat. des Reptiles*, par Sonnini, i. p. 10. Lacepede, *Hist. Nat. des Quad.* Ovip. i. Art. 1. (Translation by Kerr.)

*Testudo mydas*, Linn. *Syst. Nat.* a Gmelin, p. 1037. Schoepff, *Hist. Nat. Testudinum*, p. 73 pl. xvii. fig. 2.

*Green turtle*, Shaw, *General Zoology*, iii. pl. xxii.

2. *C. rugosa.* Wrinkled T Plates marked with three transverse black furrows; body of the shield chesnut-coloured, with a yellow margin.

*T. ridée.* Daudin, i. p 37.

3. *C. caretta.* Caret, or Hawksbill T. Shell elliptical, subcarinated, serrated; dorsal plates thirty, imbricated.

*T caret*, Daudin, i. p. 39. Lacepede, i. Art. 5.

*T. imbricata*, Linn. a Gmelin, p. 1036. Schoepff, p. 83. pl. xviii.

*Imbricated turtle*, Shaw, iii, 89. pl. 26. xxvi.

4 *C. cepediana.* Cepedian T. Feet thin shaped, furnished with one nail; plates of the breast plate 14.

*T. cépédienne*, Daudin, i. p. 49.

6. *C. caouanna.* Loggerhead T. Shell ovato-cordate, serrated; plates of the disc 15; vertebral plates gibbous behind.

*T caouane*, Daudin, i. p. 54. Lacepede, i. art. 3.

*T. caretta*, Linn. a Gmelin, 1038. Schoepff, p. 67. pl. xvi.

*Loggerhead turtle*, Shaw, iii. pl. 23, 24, 25.

6. *C. Coriacea.* Coriaceous T. Body not shelled, but covered with a leathery coat plaited longitudinally; feet fin-shaped.

*T. luth*, Daudin, i. p. 62. Lacepede, i. art. 6.

*T. ferox*, Linn. a Gmelin, 1036.
*Soft-shelled turtle*, Pennant, *Phil. Trans.* lxi. 275.
*Spinous tortoise?* *British Zoology*, vol. iv. p. 1.
*Coriaceous turtle*. Shaw, iii. p. 77. pl. 21.

Of these six species, we shall notice the first, third, fifth, and sixth more particularly.

*Species* 1. *Chelonia mydas*. Esculent, or green turtle.

Of all the Chelonian reptiles, this is deservedly held in the highest esteem, from the very nourishing and palatable food which it affords to the human race. It is also one of the largest of these tribes, and is not less interesting from its habits and manners, than from its utility as an article of diet.

A full grown turtle often measures six or seven feet in length from the nose to the tip of its short tail, three or four feet in breadth, and nearly as much in thickness at the middle of the body. It sometimes weighs eight hundred pounds. The body appears of an oval form, and the head is of considerable size in proportion to the body. The tail is short and thick. The feet are long, and much better adapted to the action of swimming than that of walking. The head, feet, and tail, are covered with scales. The breast plate is shorter than the shield, and has twenty-three or twenty-four plates disposed in four rows. The prevailing colour of this turtle's shell, when in its usual situation, is bright brown, with spots of a yellow colour; and when the shell becomes dry, the brown assumes a darker hue.

This species frequents the coasts both of the islands and continents of the intra-tropical regions, and is found in great abundance both in the East and West Indies. It sometimes enters the mouths of large rivers, and occasionally goes to some distance from the shore into the sheltered woody parts of the country. It swims with great facility, keeping its head and part of its shell above the surface of the water; but when it fears the approach of danger, or seeks its prey among the rocks, it dives to the bottom, and may be seen browsing at its ease among the weeds. It is said, however, that it does not dive very readily, as the specific gravity of its body but little exceeds that of the salt water. When it quits the water, its motion on the land is rather a scramble than a walk, and resembles that of seals and walrusses among quadrupeds, except that it is much slower.

The great purpose for which turtles go on shore, is to deposit their eggs in the sand. This process is generally begun in the month of April, and takes up several weeks, as the eggs are laid at intervals of about fourteen days. When preparing to lay her eggs, the female turtle digs a hole about two feet deep, a little above high water mark, and into this cavity she drops about a hundred eggs at one time. While thus employed, her attention is so completely taken up with the business for which she has come ashore, that a person may easily approach her from behind, and catch the eggs as they are let fall; but if disturbed before she begins to lay, she quits the place, and seeks a more secluded spot. After having deposited all the eggs which she is to lay at one time, she scratches the sand over them, and leaves them to be hatched by the heat of the sun. The eggs of this species are round, about the size of a tennis ball, and covered with a white skin resembling parchment. It is said that that part of turtles' eggs which is analogous to the albumen or white in the eggs of birds, does not coagulate by the heat of boiling water.

As the female turtle lays her eggs at three or four times, with intervals of about a fortnight, the young are of course hatched at different periods, the eggs of each laying requiring about three weeks before the young are ready for extrusion. The little animals are of the same shape with their parent, but have only a soft covering instead of a shell. As soon as they are released from their confinement, they make directly for the water; and though this be sometimes at a considerable distance, they shape their course towards it in a straight direction. But a small proportion of them, however, in general reach their natural habitation. Great numbers of them are seized by various predacious animals, especially cormorants and other large birds, which hover about the shore from May to September, for the purpose of seizing such a desirable prize.

The individuals of this species are often found collected into numerous groups, though it does not appear that they have much enjoyment of a social intercourse, but are rather attracted to the same place by the abundance of their natural food which it affords. During the coupling season, the male and female seem warmly attached to each other, and are said to continue their connubial embraces for near a fortnight together.

To what age the green turtle is capable of living, were it to remain unmolested, cannot be ascertained; but it is conjectured by those naturalists who suppose the age of an animal to depend on its size, and the number of years required for attaining its full growth, that this species must live for at least a century. We shall see hereafter that this is no uncommon age for species of a much more diminutive size.

Even in the time of Pliny, the taking of turtles for the tables of the great was practised in the East Indies; and if we may credit the accounts of Ælian and Diodorus Siculus, the barbarous nations of the East were accustomed to employ the shields of the largest individuals as canoes. It is believed that it is only within these hundred years that turtles have been imported into Europe for the purposes of food.

Various methods are resorted to in different countries for catching turtles. A very common mode is, to watch them as they go on shore, or return, during the season of laying their eggs, when they are easily arrested; and, by the united force of several persons, are turned on their backs, a position from which they find it extremely difficult to escape. Several individuals are thus turned, and when a sufficient number has been thus partly secured, they are dragged away by ropes, and carried in boats to their place of destination. This is the method practised by the inhabitants of the Bahama islands, and is often employed with success by sailors, while touching at the islands between the tropics during their long voyages. Turtles are also taken while swimming in the sea. Some fishers of great dexterity dive for such as they see at the bottom, in the shallows, and getting on their backs, press down the hind part, and raise the fore part of their body, so as to compel them to rise to the surface, where an assistant is ready to slip a noose over the head, and thus secure the captured animal. The most common mode, however, of catching turtles out at sea, is by means of a kind of spear, or harpoon, with a long wooden shaft, to which the head of the spear is but loosely attached. This kind of fishing, as it is termed, is generally carried on by two men in a small light boat or canoe. One of those persons manages the boat, while the other stands ready to dart the spear into the back of his destined victim. It is not long before a turtle is seen either swimming at the surface, or, what is more usual, feeding at the bottom, where the water is about a fathom deep. Sometimes the animal discovers the approach of his enemies, and endeavours to escape; but the men paddle after him, and generally contrive to tire him out in about half an hour's chace. The spearman then hurls his weapon, the head of which, from the peculiar construction of the instrument, generally sticks fast in the shell, while its attachment to the shaft is secured by a long string. The animal thus wounded again makes off, unless he has been so much fatigued in the chace, as to be incapable of further exertion. In either case, he soon becomes an easy prey to his pursuers.

It is only for its flesh that this species is so much esteemed, its shell being of no use. In many of the West India islands, turtles are exposed in the open market, and a turtle-steak is there as common as a beef steak in Britain. The flesh of the turtle is extremely nutritious, and is considered an excellent restorative in cases of debility and emaciation.

*Sp.* 3. *Chelonia caretta.* The imbricated or hawksbill turtle.

This species, though of considerable size, is much less than the preceding, the largest individuals seldom weighing more than three or four hundred pounds. The shield is of an oval and almost heart-shaped form, slightly sinuated before, and narrowest behind. The disc is covered with thirteen plates, that are two or three lines thick, of a smooth surface, nearly transparent, lying over each other like tiles upon a roof. The five vertebral plates are of unequal size and figure, though each is ridged longitudinally in the middle. That nearest the head is very large and quadrangular, with a semicircular margin anteriorly. The three next plates are hexagonal, and have their greatest length across the body. The fifth is pentagonal, with one angle directed backwards, and a little prolonged towards the tail. The eight lateral plates are very large, and of an irregular pentagonal figure. There are twenty-five marginal plates, which are so much imbricated as to give the sides of the animal a serrated appearance. The colour of all these plates is generally black, with irregular transparent shades of red or yellow; all of them together sometimes weigh from four to eight pounds.

We have been thus particular in describing the plates of this species, because they constitute its most valuable product. They form what in Europe is denominated *tortoise-shell*, which, by the inhabitants of the West Indies, is more properly called *turtle-shell*. The head and neck of the caret turtle are considerably longer than those of the green turtle; and the upper mandible projects so much over the lower, as to give the snout a distant resemblance to the bill of a bird of prey, whence English sailors have given it the name of hawksbill.

This species is found in the Asiatic seas, and on the Atlantic coasts of America; but is said not to be met with in the South Sea.

Though so much smaller than the green turtle, the hawksbill possesses considerable strength; and when attacked, defends itself with much ferocity, giving very severe and painful bites. It is also more difficult to secure, as its shield is more convex, and its feet longer than those of the first species; so that when turned on its back, it more readily regains its natural position. The female begins to lay her eggs in May, and continues with intervals till July. She is said not to deposit them in fine sand, but in gravel mixed with shells. The young of this species very nearly resemble those of the former.

The eggs of the hawksbill turtle are esteemed very delicious; but its flesh is unwholesome, and affects those who eat of it with fever and dysentery. It is almost entirely for the plates of tortoise-shell that it is made an object of search.

The use of tortoise-shell was known to the ancients, but it is only in modern times that the manufacture of it has been brought to perfection. In selecting the plates, those are preferred which are thick, clear, and transparent, and variegated with dark-brown, golden-yellow, red, and white. In preparing them for use, the plates are softened in warm water, and then reduced to the desired shape, by pressing them in warm iron moulds. After they are cooled, they are taken from the mould, smoothed and polished. For the purposes of inlaying in cabinet work, the moistened plates are pressed perfectly flat, and kept in that state till cool and dry. It is usual to place below them metallic leaves, of such a colour as it is wished should appear through the transparent part of the shell.

*Sp.* 5. *Chelonia caouanna.* Loggerhead, or Mediterranean turtle.

This has been sometimes confounded with the last species, under the name of *caret*, but Lacepede restricted this name to the hawksbill, in which he has been followed by succeeding naturalists.

This is a very large species of turtle, and is said by Lacepede even to exceed the green turtle in size. Its head is much larger in proportion than that of either of the former species. The mouth, and especially the upper mandible, is also of considerable size. The neck is thick, and covered with a loose wrinkled skin, thinly beset with horny scales. The shield is of an oval form, narrowest behind. It is of a yellow colour, with black spots. The legs, especially the fore legs, are proportionally longer than in many other species; and both the fore and hind feet are furnished with two sharp claws.

The individuals of this species are most abundant in the tropical seas, especially about the West India islands; but they are also found in the Mediterranean, particularly on the coasts of Sicily and Sardinia.

In its manners, this is one of the fiercest of the Chelonian tribe; it defends itself with great courage and activity, both with its mouth and claws, and has been known to snap a moderate sized walking-stick with a single stroke of its jaws. It appears to be the most predacious of all the turtles, not only feeding on shell-fish of considerable size, the habitations of which it easily breaks with its strong mandibles, but attacking the young crocodiles, seizing them by the tail as they retire backwards into the water. Thus these animals instinctively perform an act of retributive justice. The older crocodiles make a prey of the eggs and young of those turtles which inhabit the shores to which they resort, and the turtles in return seize on the young crocodiles while they are too weak to defend themselves.

The loggerhead turtle wanders very far from land. It has been seen apparently sleeping on the surface of the ocean, about midway between the Azores and Bahama islands, at a distance of many hundred miles from land. The female lays her eggs in the sand.

The flesh of this species is coarse and rank, and eaten only by the lowest classes of the people. Its body, however, affords a considerable quantity of oil, which is used for burning in lamps, and dressing leather. The plates of its shell are too thin for most purposes, but have been employed in cabinet-work.

An individual of this species, which was caught on the coast of Provence in France, was kept by Rondelet. It emitted a confused kind of noise resembling sighing.

M. Daudin reckons as varieties of this species, the *Nasicorne* of Lacepede, the Box tortoise of Catesby, the Thick-headed tortoise of Dampier, and the *Testudo macropus* of Walbaume.

*Sp.* 6. *Chelonia coriacea*, coriaceous turtle.

We notice this species here, only for the purpose of remarking, that it is sometimes confounded with the first species of the next tribe. The distinguishing characters of both will be considered more properly in a subsequent page.

## Genus II. Testudo. TORTOISES.

The *Tortoises*, under which we include the *Emydes*, *Chelydes*, and *Testudines* of Dumeril, have all the toes furnished with claws, but not distinct in all species, some having them separate, while in others the distinction is marked only by the projecting claws. The shell is generally hard and horny, but in a few species it is of a soft consistence. The tortoises feed partly on vegetables, and partly on insects, worms, snails, and similar small animals. Some of them reside on the borders of lakes and rivers; others live entirely on land. There are about 52 species, which may be divided into two Sections, according as they live most commonly on water or on land.

### Sect. I. *Fresh-water Tortoises.*

These have the toes distinct, and generally terminated by crooked claws. In some species the toes are entirely separate; in others they are more or less connected by membranes, or the feet are palmated. They live in or near fresh water, but walk easily on land. Of this Section there are about 36 species, distinguished by the following names and characters.

Species I. *Testudo Ferox.* Fierce or soft tortoise. Shell ovate, brown, leathery, tuberculated before and behind; three toes, furnished with nails; muzzle prominent, cylindrical.

*T. Ferox*, Pennant, *Phil. Trans.* vol. lxi. p. 266. Linn. a Gmelin, p. 1039. Schoepff, *Hist. Testud.* p. 88 pl. xix.

*La Tortue de Pennant*, Daudin, i. p. 69. pl. xviii. fig. 2.

*Fierce T.* Shaw, iii. p. 64. pl. xvii.

*La Tortue Molle*, Lacepede, i. art. xiv.

*Le Trionyx de Georgie*, Geoffroy, *Ann. de Mus.* xiv. p. 17.*

2. *T. Euphratica*, Euphratian T. Shield of an obscure green, leathery, not tuberculated; breastplate white and smooth.

*La T. de l'Euphrate*, Daud. i. p. 305.

*Le Trionyx de l'Euphrate*, Geoff. *Ann.* xiv. p. 17.

3. *T. bartrami.* Cirrhated T. Shell soft; feet five-toed, all the toes nailed; nose elongated, and furnished with retractile cirrhi.

*La Tortue de Bartram*, Daud. i. p. 74.

*Testudo Verrucosa Bartrami*, Schoepff, p. 90.

4. *T. rostrata.* Beaked T. Shell orbiculo-ovate, leathery, carinated, rough, streaked with oblique furrows from elevated points; nose cylindrical; three toes, furnished with claws.

*La tortue a bec*, Daud. i. p. 77.

*T. rostrata*, Schoepff, p. 93. pl. xx.

*T. membranacea*, Linn. a Gmelin.

*Le trionyx de carène*, Geoff. *Ann.* xiv. p. 14.

5. *T. granulata.* Shagreen T. Plates of the shield granulated, naked, hard; breastplate and margin of the shield cartilaginous.

*La tortue chagrinée*, Daud. i. p. 81. Lacepede, i. art. xxiv.

*Le trionyx de Coromandel*, Geoff. *Ann.* xiv. p. 16.

6. *T. matamata.* Matamata T. Shell oval, subconvex, triply carinated; feet subdigitated; nose cylindrical, lengthened into a proboscis; neck fimbriated on each side.

*La tortue matamata*, Daud. i. p. 86. pl. xx fig. 1.

*T. fimbriata*, Schoepff, p. 97. pl. xxi. Linn. a Gmelin.

*Fimbriated T.* Shaw, iii. p. 70. pl. xviii.

*Chelys fimbriata*,† Dumeril, *Zoolog. Analyt.*

7. *T. bispinosa.* Two-spined T. Dorsal plates 13, elongated, posteriorly subimbricated, wrinkled, acutely carinated; two of the marginal plates above the tail acutely two-forked.

*La tortue double-epine*, Daud. i. p. 94.

8. *T. serpentina.* Serpentine T. Dorsal plates subcarinated behind; shield marked behind with five or six tooth-like processes; feet digitated.

*La tortue serpentine*, Daud. i. p. 98. pl. xx. fig. 2. Lacepede, i. art. x.

*T. serpentina*, Linn. a Gmelin, p. 1042. Schoepff, p. 28. pl. vi.

*Snake tortoise*, Shaw, iii. pl. xix.

9. *T. spengleri.* Spenglerian T. Shield yellow, subcarinated, posteriorly six-toothed; scales imbricated.

*La tortue spenglerienne*, Daud. i. p. 103.

*Testudo spengleri*, Linn. a Gmelin, p. 1043.

10. *T. flava.* Yellow T. Shield of a blackish-brown colour, with yellow dots and lines radiated on each plate.

*La tortue jaune*, Daud. i p. 107. Lacepede, i. art. xiii.

*T. orbicularis*, Linn. a Gmelin, p. 1039.

*T. Europæa*. Schoepff, p. i. pl. i.

*Speckled T.* Shaw, iii. p. 30.

11. *T. lutaria.* Mud tortoise. Shield of a uniform dark brown colour; fibular or outermost toe of the hind feet without claw.

*La tortue bourbeuse*, Daud. i. p. 115. Lacepede, i. art. vii.

*T. lutaria*, Linn. a Gmelin, p. 1040.

*Mud tortoise*, Shaw, iii. p. 32. pl. 6.

12. *T. caspica*, Caspian T. Shell orbicular; five nails on the fore-feet, and four on the hind; head scaly; no tail.

*La tortue caspienne*, Daud. i. p. 124.

*T. caspica*, Linn. a Gmel. p. 1041.

13. *T. melanocephala.* Blackheaded T. Shell chesnut-coloured; head and feet black; tail short.

*La tortue a tête noire*, Daud. i. p. 128.

14. *T. scabra.* Rough T. Upper part of the shield rough, yellowish, irregularly spotted and striped with brown; marginal plates 25; feet palmated; one hind toe without claw.

*La tortue rabouteuse*, Daud. i. p. 129. Lacepede, i. art. xviii.

*T. scabra*, Linn. a Gmel. p. 1040.

15. *T. subrufa.* Reddish or brown T. Shell chesnut-

* This and the other Testudines, which agree in having the shield more or less coriaceous or cartilaginous, have been lately arranged under a new genus by M. Geoffroy St Hilaire, under the name of *Trionyx*, so called from their having but three claws on each foot. Of this tribe he characterizes eight species, four of which we have noticed in the list as synonymes. The rest are as follow:

1. *Tr. subplanus.* Le Tryonix Aplati. *Ann. de Mus.* xiv. p. 11.
2. *Tr. Egyptiacus.* Le Tr. d'Egypte, p. 12.
   The same with the *Testudo triunguis* of Gmelin.
3. *Tr stellatus.* Le Tr. etoilé, p. 13.
   The *Tr. cartilaginea* of Gmelin.
4. *Tr. Javanicus.* Le Tr. de Java, p. 15.

† This singular animal has occasioned the introduction of a new genus (*Chelys*) in the modern French arrangement; a nicety of distinction which we have not at present ventured to adopt. Of this genus M. Geoffroy reckons two species, and thinks there may be three. See *Ann. de Mus.* xiv. p. 18.

coloured; plates of the disc flattened, smooth in the middle, streaked on the margin; plates of the breastplate 13; all the feet five-clawed.

*La tortue roussâtre*, Daud. i. p. 132. Lacepede, i. art. xxv.

16. *T. verrucosa*. Warty T. Shell covered with warty prominences; notched round the margin; all the feet four-clawed.

*La tortue a verrues*, Daud. i. p. 134.

*T. verrucosa*, Walbaum, *Chelonograph*, p. 116.

*T. scabra*. Linn. a Gmelin, p. 1040.

17. *T. Galeata*. Helmeted tortoise. Shell oval, depressed; three dorsal intermediate plates, acutely carinated; marginal plates 24; head plated; lower mandible furnished with filiform cirrhi.

*La tortue a casque*, Daud. i. p. 136.

*T. galeata*, Schoeffp, p. 12. pl. iii. fig. 1.

*Galeated T.* Shaw, iii. p. 57. pl. xii.

18. *T. scripta*. Manuscript T. Shell orbicular, depressed; plates marked above with characters; marginal plates 25, spotted on the lower part.

*La tortue ecrite*, Daud. i. p. 140.

*T. scripta*, Schoeffp, p. 16. pl. iii. fig. 4. and 5.

*Lettered T* Shaw, iii. p. 57. pl. xii.

19. *T. porphyrea*. Porphyry T. Shell of an ochry red colour, scantily spotted with obscure green and brown; four squamous tubercles at the anus.

*La tortue porphyrée*, Daud. i. p. 142.

20. *T. reticulata*. Reticulated T. Shield streaked and reticulated with black and brown, with yellowish lines in the middle of the plates; marginal plates not toothed, three spotted at the juncture with the breastplate.

*La tortue reticulaire*, Daud. i. p. 144. pl. xxi. fig. 3.

21. *T. serrata*. Serrated T. Shell marked above with transverse brown and yellow bands; posterior marginal plates not toothed; lateral margin at the juncture of the breastplate five-spotted.

*La tortue a bord en scie*, Daud. i. p. 148. pl. xxi. fig. 1, 2.

22. *T. centrata*. Concentric T. Dorsal and marginal plates marked with two or four black concentric circles; breastplate yellow, without spots, notched behind.

*La tortue a lignes concentriques*, Daud. i. p. 153.

*Concentric tortoise*, Shaw, p. 43. pl. ix.

23. *T. punctata*. Dotted T. Shell oval, moderately convex; dorsal plates and head smooth and black, dotted with yellow.

*La tortue ponctuée*, Daud. i. p. 159. pl. xxii.

*T. punctata*, Schoepff, p. 25. pl. v.

*Spotted T.* Shaw, iii. p. 47. pl. x.

24. *T. picta*. Painted T. Shield oblong, convex, very smooth; plates nearly square, brown, bordered with yellow; breastplate as long as the shield.

*La tortue peinte*, Daud. i. p. 164.

*T. picta*, Linn. a Gmelin, p. 1045. Schoepff, p. 20. pl. iv.

*Painted tortoise*, Shaw, iii. p. 45. pl. x.

25. *T. martinella*. Martinella T. Shell a little flattened, oval, marked on the back with two longitudinal ridges; plates of the breastplate 13.

*La tortue martinelle*, Daud. viii. p. 344.

26. *T. tricarinata*. Three-ridged T. Shell orbicular; three-ridged, vertebral plates transverse.

*La tortue retzienne*, Daud. i. p. 174.

*T. tricarinata retzii*, Schoepff, p. 9. pl. ii.

*Tortue a trois carênes*, Latreille, *Hist. des Rep.* i. p. 118.

*Tricarinated T.* Shaw, iii. p. 54. pl. xi.

27. *T. scorpioides*. Scorpion T. Shell oval, longitudinally three ridged; vertebral plates oblong, posteriorly imbricated.

*La tortue a trois carênes*, Daud. i. p. 178.

*La tortue scorpion*, Lacepede, i. art. xii.

*T. scorpioides*, Linn. a Gmelin, p. 1041.

28. *T. amboinensis*. Amboyna T. Shield convex, smooth, brown, both it and breastplate bordered with yellow; head compressed, brown, cheeks and beak radiated with yellow; feet palmated.

*La tortue d'amboine*, Daud. viii. p. 345.

29. *T. Pennsylvanica*. Pennsylvanian T. Upper part of the shield smooth, uniformly reddish, flattish in the middle; three of the vertebral plates hexagonal, oblong, imbricated behind, the first and fifth being elongated, and nearly triangular; marginal plates 25; tail tipped with a claw.

*T. rougeatre*, Daud. i. 182. pl. xxiv. Lacepede, i. art. 2.

*T. Pennsylvanica*, Linn. a Gmel. i. 1042. Schoepff, pl. xxiv. fig. A.

*Pennsylvanian T.* Shaw, iii. p. 60. pl. xiv.

30. *T. odorata*. Odorous T. Shield smooth, uniformly brownish, flattish in the middle; marginal plates 23; breastplate moveable only in front; tail tipped with a claw.

*T. odorante*, Daud i. 189.

3. *T. glutinata*. *T. a batans soudées*, Daud. i. 194. This, which is marked by Daudin as a distinct species, seems to be only a variety of the preceding, differing in the immobility of the breastplate.

32. *T. subnigra*. Blackish T. Shield rounded, convex; plates streaked at the margin, smooth in the middle; vertebral plates carinated; plates of breast plate 13.

*T. noiratre*, Daud. i. 197. Lacep. i. art. 28.

33. *T. virgulata*. Striped T. Shell dark brown, with numerous yellow spots; vertebral plates longitudinally carinated.

*T. a goutellettes*, Daud. i. 201.

34. *T. clausa*. Close T. Shell brownish, striped on the back with yellow; vertebral plates longitudinally subcarinated; middle of the breastplate a little compressed.

*T. a baite*, Daud. i. 207.

*Close tortoise*, Shaw, iii. p. 36. pl. vii.

35. *T. carolineana*. Carolina T. Shell brown bay, marked above with yellow lines and spots; dorsal plates striated; vertebral plates longitudinally carinated, lateral subgibbous.

*T. courte-queue*, Daud. i. 207. Lacep. i. art. xxv.

*T. carolina*, Linn. a Gmel. 1041, 1042.

*T. clausa*, Schoepff, p. 32. pl. vii.

36. *T. squamata*. Scaly T. Shell ovate; body, neck, tail and feet scaly above, smooth and soft below.

*T. ecailleuse de Bontius*, Daud. i. 216.

*T. squamata*, Linn. a Gmel. 1040. No. 2.

### Sect. II. *Land Tortoises.*

In the species that belong to this section, the toes are not distinct from each other, but are united below the skin into one broad expansion, from the margin of which appear the claws. They however walk, though with a very slow pace, on the ground; and live chiefly on worms and insects. There are 16 species, viz.

*Species* 37. *T. græca*. Common land T. Shield hemispherical; plates of the disc subconvex, vertebral plates subgibbous; marginal 25, obtuse at the sides; the whole shield black and yellow. See Plate CCXCVI. Fig. 2.

*La T. grecque*, Daud. i. 218. Lacepede, v. i. p. 1. art. xvi. pl. 8.

*Testudo græca*, Linn. a Gmelin, p. 1043. Schoepff, p. 38. pl. viii.

*Common tortoise*, Shaw, iii. p. 9.

38. *T. marginata*. Bordered T. Shield oblong, convex, gibbous; dorsal plates blackish-brown, with a shade of

yellow in the middle; marginal 23 or 24, obliquely marked with black and yellow.

*T. bordée*, Daud. i. 233.

*T. marginata*, Schoepff, p. 52. pl. ii.

*Marginated tortoise*, Shaw, iii. p. 17.

39. *T. tabulata*. Inlaid T. Shield oblong, gibbous; plates of the disc rectangular, subgibbous, furrowed, black, with yellow lines; marginal plates 23, black with yellow below.

*T a masqueterie*, Daud. i. 242.

*T. tabulata*. Linn. a Gmel. 1045.

*Tabular tortoise*, Shaw, iii. p. 41. pl. viii.

40. *T. punctularia*. Spotted T. Shell a little flattened, broad, subcarinated; breast plate nearly of the same length with the shield; head black above, spotted with yellow, entirely yellow below. Daud. i. 249.

41. *T. polyphemus*. Gopher T. Snout slender and sharp; plates thin, of a greyish ash colour; claws flat and roundish. Daud. i. 256.

*T. gopher*, Bartram's *Travels*.

42. *T. geometrica*. Geometrical T. Shell ovate; all the plates elevated, but flat on the top, marked with yellow streaks radiating from a centre in each plate.

*T. geometrique*, Daud. i. 260 Lacepede, i. art. xvii.

*T. geometrica*, Linn. a Gmelin. p. 1044. Schoepff, p. 49. pl. x.

*Geometrical tortoise*, Shaw, iii. p. 20.

43. *T. elegans*. Elegant T. Shell hemispherical; plates furrowed, convex, four-striped, with flat areolæ broader than long.

*T. elegante*, Daud. i. 266.

*T. elegans*, Shoepff, p. 111. pl. xxv.

44. *T. coui*. Shield round, highly convex; plates furrowed, flattened, with prominent red areolæ; three middle vertebral plates radiated of a deep yellow laterally; lateral plates radiated below.

*La tortue coui*, Daud. i. 271. pl. xxvi

45. *T. luteola*. Yellowish T. Shield rounded, gibbous, yellow, with subgibbous plates.

*T. luteole*, Daud. i. 277.

46. *T. indica*. Indian T. Shield convex; anterior marginal plates reflected upwards.

*La tortue indienne*, Daud. i. 280.

*T. indica*, Linn. a Gmelin. Schoepff, p. 101. pl. xxii.

*Indian tortoise*, Shaw, iii. p. 25.

47. *T. areolata*. Areolated T. Shield ovato-oblong, moderately convex; plates nearly square, elevated, deeply furrowed, with rough depressed areolæ.

*La T. areolée*, Daud. i 287.

*T. areolata*, Schoepff, p. 104. pl. xxiii.

48. *T. cafra*. Cafre T. Shield flattish, broad; plates flat, except the last vertebral, which is gibbous; yellow, elegantly sprinkled with black dots; marginal plates of the shield 27.

*La T cafre*, Daud. i. 291.

49. *T. juvencula*. Juvencula T. Shield square, oblong, little gibbous, with concave grained areolæ: plates of the disc 13, yellow, with black radiated points; marginal plates 26.

*La T. juvencule*, Daud. viii. p. 348.

50. *T. fasciata*. Banded T. Shield brown-bay, with a white transverse band in the plates of the disc; first vertebral plate carinated; marginal plates 27.

*La T. a fasciés blanches a Ceilon*, Daud. i. p. 294.

51. *T. pusilla*. Dwarf T. Plates of the shield variegated with black, white, purple, green, and yellow; breast-plate white; a red tubercle on the neck.

*La T. vermillon*, Daud. i. 299. Lacepede i. art. xxii.

*T. pusilla*. Linn. a Gmelin, p. 1044.

*African land tortoise*, Edwards' *Gleanings*.

52. *T. denticulata*. Denticulated T. Shield orbiculate cordate, denticulated at the margin; plates hexagonal; feet four-clawed.

*La T. dentilé*. Daud. i. p. 303. Lacepede, i. art. xix.

*T. denticulata* Linn. a Gmelin, p. 1043.

*Denticulated T.* Shaw, p. 59. pl. xiii.

Species I. *Testudo ferox* Fierce tortoise.

There are several species of the Chelonian order which have the shield softer than the ordinary shell of most species. This is the case with the 6th species of the former tribe, and with at least four of the present. The coriaceous turtle, or *Luth* of the French writers, and the soft-shelled tortoise of Pennant, though agreeing in the comparative softness of their external covering, differ very materially in general form, habitation and manners. The coriaceous turtle has an oblong body, covered immediately with a bony shell: but that shell is invested with a tough membranous coat resembling leather, plaited longitudinally, and the shield terminates behind in an acute point, overhanging the tail. The body of the fierce tortoise is rounder and more convex, and the middle part of the shield is hard; but its margin, especially towards the tail, is soft and pliable, resembling thin sole-leather, and the hind part is rounded. The tail of the first species is long, and very thick at the root; that of the second very short and small. The head of the former is small, round, and terminates in a beak, resembling the bill of a bird; that of the latter is proportionally larger and longer, with a long tapering cylindrical snout, having some resemblance to that of the mole. The coriaceous turtle is an inhabitant of the sea, is frequently found in the Mediterranean, and has been seen even on the coast of Britain. The fierce tortoise has yet been found only in the rivers and fresh water lakes of America, especially in Florida and Carolina. The former is a large species, often measuring above seven feet in length; the latter seldom weighs above seventy pounds.

The fierce tortoise frequents lakes and muddy rivers, and hides itself among the water plants that grow at the bottom, from which it is said to spring suddenly on its prey. This consists of small water animals, and, in some places, more particularly of young crocodiles, of which this species is extremely fond. They seize their prey by suddenly darting forward their long and strong neck, which they do with great celerity.

This species is among the strongest and most active of its tribe, and, as its trivial name implies, is possessed of ferocity and courage. When attacked, it boldly defends itself, rising on its hind legs, and leaping forward to seize on its assailant; and if once it fixes with its jaws on any part, it is scarcely made to let go its hold without cutting off its head.

The fierce tortoise forms an excellent article of food, at least not inferior to the green turtle.

Sp. 11. *T. lutaria*. The mud tortoise.

This is one of the smallest of the fresh water tortoises; its whole length, from the snout to the tip of the tail, seldom exceeding eight inches, while in breadth it is not more than three or four. It is of a blackish or dark brown colour. Its tail is nearly half the length of the shield, and is stretched out when the animal walks. Hence the mud tortoise has been sometimes called by the ancients, *mus aquatilis*, or water rat.

This is a very frequent inhabitant of lakes and muddy rivers in the south of Europe, and in many parts of Asia. It is very plentiful in France, especially in the provinces of Languedoc and Provence. It lives almost entirely in the water, only going on land to lay its eggs, which it covers with mould. It moves with a quicker pace on land than many of this tribe; when disturbed, it utters a kind of interrupted hissing sound. It feeds on fish, snails, and worms, and often proves a troublesome inmate in fish-ponds, killing many of the fish, and biting others till they are nearly exhausted from loss of blood.

It has been proposed to employ the mud tortoise for destroying vermin in gardens; but it is necessary to have a pond or large vessel of water for its ordinary residence. With such a convenience, it may be rendered tame and domestic.

The young of this species, when first hatched, are not an inch in diameter. They continue to grow for a long time, and are known to live for at least twenty-four years.

Sp. 36. *T. Græca.* Common land tortoise.

Several varieties of tortoise, known both to ancient and modern naturalists, have been described under the name of *Greek;* and, according to Daudin, Schoepff was the first to remedy this confusion, and to mark each by its distinctive characters. The species of which we are now treating seldom exceeds ten inches in length; is of an oval form, with a very convex shield, broader behind than before. The breastplate is nearly of equal size with the shield, and is of a pale yellow colour, with a broad dark stripe down each side, while the middle part of the shield is of a blackish brown, mixed with yellow. The head is small, and covered on its upper part with irregular scales; the mouth is small, the legs short, and the feet pretty broad, and covered with strong ovate scales. The tail is very short, scaly, and terminated at its extremity with a curved horny process. It seldom weighs above three pounds.

This species is entirely confined to the land, and prefers elevated woody situations. It is found in Europe, Asia, and Africa, and is very common on all the coasts of the Mediterranean Sea, especially in Sardinia, Barbary, and probably in Egypt. It is not a little curious, that, even in the warmer climates, this species regularly retires to its subterranean quarters during the winter months; thus proving what we have before remarked, that the hybernation of these animals does not depend solely on the degree of cold. It begins to bury itself in October, and usually makes a hole about two feet below the surface, where it continues till April.

The males of this species are in summer tolerably active, and very fierce towards each other. The female lays her eggs towards the end of June, depositing them in a hole, and covering them with sand or mould. They seldom exceed five in number at one time, and are of a white colour, and about the size of those of a pigeon. They are hatched towards the end of September; and the young, when first extruded, are scarcely bigger than walnut-shells.

The individuals of this species live on roots, fruits, worms, and insects, the shells of which latter they easily break with their strong jaws.*

The land tortoise is often domesticated, especially in gardens. We shall select the account of a tame tortoise, given by the Rev. Mr. White of Selborne, as a pleasing specimen of the manners of these animals in a state of captivity. This individual had been in possessien of a lady for upwards of thirty years. It regularly retired below ground about the middle of November, and did not emerge till the middle of April. Its appetite was voracious in the middle of summer, but it ate very little in spring and autumn. It seemed greatly alarmed if surprised by a shower of rain during its peregrinations in search of food; and though its shell was so thick that it could scarcely have been injured by the wheel of a loaded cart, it discovered as much solicitude to avoid rain, as a fine lady in her gayest attire, shuffling away on the first sprinklings, and making for some shelter. Whenever the old lady, its mistress, who usually waited on it, came in sight, it always hobbled, with awkward alacrity, towards its benefactress, though to strangers it appeared quite inattentive. It never stirred out after dark; often appeared abroad only for a few hours in the middle of the day; and in wet days never came from its retreat. Though it loved warm weather, it carefully avoided the hot sun, and passed the more sultry hours under the shelter of a large cabbage leaf, or amid the friendly shades of an asparagus bed. Towards autumn, however, he appeared anxious to improve the effect of the faint sunbeams, by getting under the reflection of a wall, and inclining its shell towards the sun. In scraping the ground to form its winter retreat, it dug with its fore feet, and threw up the earth over its back with its hinder feet; but the motion of its legs was so slow, as scarcely to be observed; and though it worked with the greatest assiduity both night and day, it was more than a fortnight before it had completed its inhumation.

How long an animal of this species may live, we cannot determine; but it is known at least, that their age may exceed a century. One of them was introduced into the garden of Lambeth palace in the time of Archbishop Laud, was living a hundred and twenty years afterwards, and died at last rather from the neglect of the gardener than from excessive age.

The land tortoise forms an excellent article of food, though it is scarcely employed for that purpose except in Greece. The eggs, however, are eaten very commonly in Italy.

Daudin enumerates eight varieties of the Greek tortoise, all of which are of a very diminutive size, and differ chiefly in the surface and variegations of the shield.

Among the numerous fossil remains of an ancient world that have lately been discovered, are several that belong to the tortoise tribes. These have been found at Malta; in the environs of Berlin; in the forest of Leipsic; at Aix in the south of France; in the neighbourhood of Brussels; in the mountains of St Pierre near Maestricht; and in the plaster quarries near Paris. These remains have been described by Faujas de St Fond, in his account of the mountain of St Pierre, and by Cuvier in the 14th vol. of the *Annales de Muscum*, p. 229. From these accounts we gather, that, besides many species either now extinct, or to us unknown, remains have been found of the *green turtle*, of the *imbricated*, *caretta*, and *coriaceous* turtles; and of at least one species (*T. flava*, or *Europea*) of fresh water tortoises.

* We do not remember to have seen, in any author with which we are acquainted, that land tortoises are accustomed to drink. The writer of this article has lately, however, ascertained the fact, that although they can live without drink for years, they swallow liquids with pleasure and avidity when offered to them in the spring. A land tortoise, which has been in the possession of a carpenter at Portobello, near Edinburgh, for above six years, was never known to drink of its own accord till the spring of this year (1816), when it has repeatedly drunk water set before it. Its mode of drinking is peculiar. It puts down its head deep into the fluid, so as to cover even its eyes, and then gradually, and almost imperceptibly, sucks it up, so as to drink some ounces in the course of a quarter of an hour.

## Order II. SAURIAN REPTILES.

Besides what we have said respecting this order, in our general arrangement, p. 5. we may remark, that, in most of the species, there is no sensible neck, or remarkable contraction between the head and body; that they have all a lengthened thorax, protected by the ribs; that their tail is most commonly rounded, though in some tribes it is compressed laterally, then serving the purpose of a fin, being very seldom prehensile. The limbs, which are always short, are in a few instances only two in number. The number of the toes and of their component joints, as well as their form and respective situation, differ considerably. All the species change their skin every spring. Their jaws, though they commonly expand very considerably, never separate from each other at the articulation, as we shall hereafter find to be the case with serpents. They all feed on living animals. Their voice is weak, and resembles a dull hiss or whistle. They copulate, lay eggs covered with a calcareous or membranous shell, which they deposit in the earth or sand, but do not assist in hatching them. They are in general very active and voracious. Most of the species are inhabitants of the warmer climates, few of them being found in the northern countries. It has been remarked, that in this order are found nearly the largest and the smallest of the perfect animals.

### Family I. *Sauri Planicaudati.* Flat-tailed Saurians.

### Genus I. Crocodilus. CROCODILES.

In this tribe, the back and belly are covered with large plates; the head is broad and flat; the tongue short, fleshy, and adhering to the lower jaw; the tail very much compressed, and armed above with a serrated crest, at first double, but single towards the tip. They have four strong feet, of which the hinder have five toes, more or less palmated, only three being furnished with nails. All the species are capable of living both in water and on land; they generally inhabit the former, but move with ease upon the latter.

Daudin has enumerated seven species, which he arranges under three Sections, as follows:

#### Sect. I. *Crocodiles properly so called.*

Snout long and flat; one tooth on each side of the lower jaw, prolonged outwards, and shutting into a groove in the upper jaw.

Species 1. *Crocodilus niloticus.* Nilotic crocodile. Muzzle flat and oblong; fourth tooth of the lower jaw resting against the edge of the upper jaw; six large carinated plates upon the neck. Plate CCXCVI. Fig. 3.

*Le crocodile de Nil*, Daud. ii. p. 367, pl. xxvii. fig. 1.

*Le crocodile*, Lacepede, i. part ii. art. 1.

*Lacerta crocodilus*, Linn. a Gmelin, p. 1057.

*Common crocodile*, Shaw iii. pl. lv. lvi. lvii.

Under this species, Daudin ranks, as varieties, the crocodile of Senegal, the black crocodile, and the Indian crocodile.

#### Sect. II. *Gavials.*

Muzzle lengthened, narrow, nearly cylindrical; two teeth at least on each side of the lower jaw, prolonged upwards beside the upper jaw.

*Sp.* 2. *C. longirostris.* Long-beaked crocodile. Muzzle double the length of the head; both jaws furnished with 27 teeth on each side; four carinated plates, disposed in a square upon the neck.

*Le crocodile à long bec*, ou *le petit gavial*, Daud. i. 389.

*Sp.* 3. *C. Arctirostris.* Narrow-beaked C. Gangetic C. Muzzle narrow, as long as the head; upper jaw furnished with 28 teeth on each side; lower jaw with only 25 on each side; two carinated plates upon the neck.

*Le crocodile à bec etroit*, ou *le grand gavial*, Daud. i. 393. pl. xxvii. fig. 2.

*Le gavial*, Lacepede, vol. i. part ii. art. 3. pl. xii. fig. 2.

*Lacerta gangetica*, Linn. a Gmel. p. 1057.

*Long-nosed crocodile*, Edwards, *Phil. Trans.* xlix. p. 639. pl. xix.

*Gangetic crocodile*, Shaw, iii. p. 197. pl. lx.

#### Sect. III. *Caïmans.*

Muzzle broad, flat, and obtuse; the fourth tooth of the lower jaw received into a particular cavity of the upper jaw, by which it is concealed.

*Sp.* 4. *C. caïman.* Caïman crocodile. Beak flat, a little narrower than the head; jaws furnished with 19 teeth on each side; 14 carinated plates, disposed in five rows upon the neck.

*Le crocodile caïman*, Daud. i. p. 399.

*Lacerta alligator*, Linn. a Gmel. p. 1058. No. li.

*Alligator*, Shaw, iii. p. 192. pl. lix.

*Sp.* 5. *C. yacare.* Yacare C. Muzzle blunt, a little elevated; jaws furnished with 19 teeth on each side; two fore teeth of the lower jaw elongated, and passing through the upper jaw. Daud. i. p. 407.

*Sp.* 6. *C. Mississippiensis.* Mississippi C. or alligator. Muzzle broad and flattened; four carinated scales, disposed in a square upon the neck.

*Le crocodile du Mississippi*, Daud. i. p. 412.

*Alligator*, or *Florida crocodile*, Bartram's *Travels in South America.*

*Sp.* 7. *C. latirostris.* Broad-beaked crocodile. Muzzle broad and flattened; jaws furnished with 19 teeth on each side; eight scales, disposed in four pairs upon the neck.

*Le crocodile a large museau*, Daud. i. p. 417.

Perhaps this may be considered as a variety of the alligator, from which it appears to differ only in the number and disposition of the plates on the neck.

Such is the arrangement of Daudin. We must now notice the classification of Cuvier, as given in the 10th volume of the *Annales de Museum.*

#### *Essential Characters of the Genus.*

Tail flattened at the sides; hind feet palmated or semipalmated; tongue fleshy, attached to the floor of the mouth, except at its edge; teeth sharp, simple, ranged in a single row; penis single.

#### *Subgenera and Species, with their essential Characters.*

#### Subgenus I. *Alligators.* (Sect. III. Daudin.)

Species 1. *Cr. lucius.* Muzzle parabolic, depressed; scales on the neck four. Native of North America.

2. *Cr. sclerops.* A transverse ridge between the orbits;

neck furnished with four bony bands. Native of Guiana and Brasil.

3. *Cr. palpebrosus.* Bony palpebræ; neck furnished with four bony bands.

4. *Cr. trigonatus.* Bony palpebræ; neck furnished with irregular triangular carinated scales.

SUBGENUS II. *Crocodiles.* (Sect. I. Daudin.)

5. *Cr. vulgaris.* Muzzle equal; scales of the neck six; those of the back in sixes, square. Native of Africa.

6. *Cr. biporcatus.* Muzzle furnished with two ridges nearly parallel; plates of the neck six; scales of the back in eights, oval. Native of the Indian islands.

7. *Cr. rhombifer.* Muzzle sub-convex, with two converging ridges; plates of the neck six; scales of the back in sixes, square, those of the limbs thick and carinated.

8. *Cr. galeatus.* Top of the head furnished with a two-toothed elevated crest; plates of the neck six. Native of India beyond the Ganges.

9. *Cr. biscutatus.* Intermediate scales of the back square; outer ones irregular both in form and situation; plates of the neck two.

10. *Cr. acutus.* Intermediate scales of the back square; outer ones irregular; plates of the neck six; muzzle elongated and convex at the base. Native of the Antilles.

SUBGENUS III. *Longirostres, or Gavials.* (Sect. II. Daud.)

11. *Cr. gangeticus.* Top of the head and orbits transverse; two small plates on the neck.

12. *Cr. tenuirostris.* Top of the head and orbits contracted; four small plates on the neck.

M. Geoffroy St Hilaire, in a second Memoir on Crocodiles, in the tenth volume of the *Annales de Museum*, has formed another species of Nilotic crocodile, under the trivial name *Suchos*; but his account of it is not sufficiently precise to determine its specific differences.

As we have already, under the article CROCODILE, given a comprehensive account of the three principal species of this tribe, viz. the crocodile of the Nile, the alligator, and the Gangetic crocodile, or *caïman*, we shall at present dispense with any thing more on the natural history of these animals.

GENUS II. DRACÆNA. DRAGON.

In this genus the body is covered with large rounded scales, (those upon the back being carinated,) disposed in transverse bands, and separated by numerous other very small scales that are round and carinated. The head is thick, compressed laterally, and covered at the top with several smooth scales. Some of the teeth in the fore part of the jaws are sharp-pointed, and those behind are broad and flat like the molares of quadrupeds. The tongue is forked at its distal extremity; and the tympanum of the ear is apparent externally of a round form. The lower part of the body is covered with smooth scales, disposed in transverse bands. The tail is covered on that half next the body with plates, which form on its upper part first four, and then two toothed ridges, while the remaining half is covered with rough rhomboidal scales, carinated and imbricated. The four feet are each furnished with five long toes, completely separated from each other, and terminated by claws.

There is only one species, viz.

SPECIES 1. *Dracæna guianensis.* Guiana dragon.

*La Dragone de la Guian*, Daud. i. p. 423. pl. xxviii.

*La Dragone*, Lacepede, vol. i. part. ii. art. 5. pl. xiii.

*Lacerta dracæna*, Linn. a Gmelin, p. 1059.

*Dracæna lizard.* Shaw, iii. p. 218. pl. 67.

See Plate CCXCVI. Fig. 4.

This animal in many respects resembles the smaller crocodiles, differing from them chiefly in its forked tongue and distinct toes. It is of a reddish-brown colour, shaded with green. It is from two to four feet in length, of which the tail is about one half. This latter organ is very thick at its proximal extremity, tapering gradually towards the point, and is strong and flexible.

The dragon has hitherto been found only in South America, and chiefly in Guiana. It is a land animal, frequents the savannahs and marshy plains; readily climbs trees, and hides itself when in danger from crocodiles or other enemies. Both its flesh and eggs are used as articles of food.

GENUS III. BASILISCUS. BASILISK.

The body in this tribe is thicker in proportion to its length than many of the order; and its whole surface, as well as that of the head, neck, tail, and limbs, is covered with small scales, that are generally rhomboidal and a little carinated. The head is short and pretty thick, especially towards the back part; the tongue broad, thick, flat, rounded at its tip, not extensile, and almost wholly attached within the lower jaw. The throat is susceptible of inflation. The tail is long, very much compressed laterally, and surmounted, at least along its anterior half, with a high vertical crest that is radiated, capable of being folded together, and scaly. The feet are rather thick and long, and furnished each with five toes, terminating in claws.

There are two species, viz.

*Species* 1. *Basiliscus mitratus.* Mitred basilisk. Tail long and pointed; back of the head surmounted with a very high mitre-shaped membrane. See Plate CCXCVI. Fig. 5.

*Le Basilic proprement dit*, ou *a capuchon*, Daud. iii. p. 310. pl. xlii.

*Le Basilic*, Lacepede, vol. i. part ii. art. 14.

*Lacerta basiliscus*, Linn. a Gmelin, 1062.

2. *B. amboinensis.* Amboina B. Tail long; head naked, dorsal crest pectinated.

*Le B. porte-crète d'Amboine*, Daud. iii. p. 322.

*Le porte-crète*, Lacepede, vol. i. part ii. art. 15.

*Lacerta amboinensis*, Linn. a Gmelin, p. 1064.

The animals above characterised, though singular in their external appearance, have nothing of the terrible aspect and deadly properties of the basilisk, so renowned among the writers of antiquity. See BASILISK. They are harmless inoffensive creatures, enlivening the woods of America and Asia with their active motions. Assisted by the crest on their back and tail, they leap with agility from branch to branch, though they have no pretensions to flying, as was supposed by Seba. It is not certain whether they frequent the water, but if they do, their crested membranes must act as fins.

GENUS IV. TUPINAMBIS.

The animals of this tribe have the back and belly covered with small scales disposed in transverse lines. The head is covered with numerous small scales, and, as well as the neck, is long and thin. The tongue is long, extensile, and forked. The body is long and slender, but of a robust make. The tail is very long, and taper; rounded at its base, slightly verticillated, or ringed, furnished with a very small double ridge in some species, but smooth in others. The feet are strong, and have each five toes separated and furnished with claws.

The tupinambes are very active, live both on land and in the water, feed on insects, snails, and worms, and sometimes on wood mice, fruits, and fishes. The larger species seek greedily after the eggs of crocodiles, although they carefully avoid the young of those animals, which, in their turn, prey on the tupinambes. They are all natives of warm climates, and are found chiefly in South America, Egypt, and the East Indies.

Daudin has characterised fourteen species, which he distributes under two Sections as follows:

Sect. I. *Tupinambes with the Tail compressed and simple.*

*Species* 1. *Tupinambis monitor.* Safeguard tupinambis. Head covered with pretty large scales; back black, with four longitudinal lines and transverse white bands, irregularly disposed; belly whitish, with black shades; tail very little compressed.

*Le Tupinambis proprement dit*, ou *Sauvegard*, Daud. iii. p. 20.

*Le Tupinambis*, Lacep. i. part ii. art. 6. pl. xiii. fig. 2.

*Lacerta monitor*, Linn. a Gmelin, p. 1059.

*Monitory lizard*, Shaw, iii. p. 214. pl. lxvi.

2. *T. elegans.* Elegant T. Brownish with white concentric lines above the head and neck, nine transverse bands of round white spots upon the back; the belly white with interrupted transverse brown lines; tail very much compressed.

*Le T. elegans*, Daud. iii. p. 36.

3. *T. cepedianus.* Cepedian T. Brownish above, with from 23 to 24 transverse rows of spots; white on the fore part of the body, and black on the hinder; whitish below, with interrupted transverse brown lines.

*Le T. cepedian*, Daud. iii. p. 43. pl. xxix.

4. *T. indicus.* Indian T. Black above, with confusedly scattered white dots.

*Le T. indien*, Daud. iii. p. 46. pl. xxx.

5. *T. maculatus.* Spotted T. Black above, irregularly marked with transverse bands, and seven longitudinal rows of greenish spots on the upper part; neck plaited below; tail half the length of the body.

*Le T. a taches vertes*, Daud. iii. p. 48.

6. *T. griseus.* Gray T. Yellowish-gray without spots, paler below; scales nearly hexagonal, granulated on their margin; tail nearly cylindrical, and as long as the body.

*Le T. gris d'Egypte*, Daud. viii. p. 352.

Sect. II. *Tupinambes having the Tail surmounted with a small double Crest, slightly serrated.*

7. *T. stellatus.* Stellated T. Blackish-brown above, with transverse bands of small whitish circular spots, interspersed with whitish dots; tail long.

*Le T. etoilé d'Afrique*, Daud. iii. p. 59. pl. xxxi.

8. *T. niloticus.* T. of the Nile. Differs from the former in having the acellated spots and dots irregularly disposed. Probably a variety. See Daud. viii. p. 353.

9. *T. bengalensis.* Bengal T. Ash-coloured above, spotted with white and black; black bands across the cheeks; throat dotted with black; whitish below; tail long.

*Le T. piqueté de Bengale*, Daud. iii. p. 67.

10. *T. ornatus.* Ornamented T. Body black; throat white, radiated with nine transverse black bands; with seven transverse rows of round white spots upon the back; and from twelve to eighteen whitish rings round the tail. See Plate CCXCVI. Fig. 6.

*Le T. orné*, Daud. viii. p. 307. *Ann. de Mus. de Hist. Natur.* tom. ii. p. 240. pl. xlviii.

11. *T. albigularis.* White-throated T. Lower part and sides of the head and neck whitish, spotted with brown; two whitish lines extending from the eyes to the neck; tail long.

*Le T. a gorge blanche*, Daud. iii. p. 72. pl. xxxii.

12. *T. variegatus.* Variegated T. Blackish above, variegated with double transverse rows of round yellow lines and shades; tail twice as long as the body.

*Le T bigarré*, Daud. iii. p. 76.

*Variegated lizard*, White, *Voyage to N. S. Wales*, p. 253.

13. *T. exanthematicus.* Pimply T. Black-coloured, with roundish white spots irregularly disposed; belly marked with brown bands; two black lines behind the eyes; head scaly above; tail of moderate length.

*Le T. exanthematique de Senegal*, Daud. iii. p. 80.

14. *T. lacertinus.* Lizard T. Some carinated scales along the back; eight longitudinal rows of smooth plates below the belly; tail long, with a small double crest at its base.

*Le T. lizardet*, Daud. iii. p. 85.

*Le Silonné.* Lacepede, i. part ii. art. 11.

*Lacerta bicarinata*, Linn. a Gmelin, p. 1060.

Genus V. Iguana. GUANAS.

The individuals of this tribe resemble those of the last, in having the body and tail surrounded with numerous small rings of minute scales that are nearly of a square figure, and in sometimes having the tail a little compressed at the sides, though this is in a small degree. A high crest composed of numerous pointed scales, resembling the teeth of a comb, extends along the *vertebræ* from the neck to near the tip of the tail. The head is somewhat pyramidal, and has four sides; the tongue is broad, flat, fleshy, but little extensile, and a little notched at its tip; and below the throat is a pendulous inflated skin, compressed laterally, and furnished at its fore part with a crest resembling that on the back and tail. The feet are strong, each having five toes ending in claws, and under each thigh is a row of small porous tubercles. The Guanas are found both in the E. and W. Indies; and chiefly inhabit the woods, sporting among the trees. There are three species. viz.

*Species* 1. *Iguana delicatissima.* Common guana. Swelling of the throat pectinated anteriorly; dorsal and caudal crest pectinated; forehead and muzzle covered with smooth plates. Plate CCXCVI. Fig. 7.

*L'Iguane ordinaire*, Daud. iii. 263. pl. xl.

*L'Iguane*, Lacepede, vol. i. part ii. art. 12.

*Lacerta iguana*, Linn. a Gmelin. p. 1062.

*Common guana*, Shaw, iii. pl. lxi.

2. *I. cornuta.* Horned G. Swelling of the throat anteriorly pectinated; forehead beset with tubercles, especially one resembling a horn.

*L'Iguane cornu*, Daud. iii. 282.

*Le lezard cornu*, Lacepede, vol. i. part ii. art. 13.

3. *I. cærulea.* Blue G. Bluish-black, without spots; a longitudinal row of pointed scales on each side of the neck.

*L'Iguane ardoisé.* Daud. iii. p. 286.

*Species* 1. *Iguana delicatissima.* Common guana.

This animal, after the crocodile and the dragon, is one of the largest of the Saurian order, being not unfrequently found from four to six feet long from the muzzle to the tip of the tail. In its general appearance, exclusive of its colours, it is clumsy and unsightly, and occasionally even assumes a terrific aspect. Its head is large and thick; its belly protuberant; its tail very long, thick at its commencement, and tapering gradually towards a sharp point. Its serrated back, tail, and throat, its long toes armed with sharp crooked claws, and its jaws with numerous sharp teeth, are sufficient to alarm an observer who is unacquainted with its history. To counterbalance these deformities, however, its whole surface is covered with numerous shining scales, of the most brilliant appearance, reflecting various colours when viewed in the sunshine, though the prevailing tint is a brownish green.

The guana is found both in South America and the West Indies, where it inhabits the forests, especially near the borders of lakes or the banks of rivers. It sometimes ascends the highest trees in quest of insects; at others, seeks its prey among the grass and underwood. It is a harmless, inoffensive animal, and soon becomes familiar with mankind. Its flesh forms a delicious article of food, and is either roasted fresh, or salted and barrelled up for exportation, by the inhabitants of those islands where it is most frequent. It is said that the negroes are very expert in catching this animal, amusing it by whistling, and, when it suffers them to approach, tickling it with the end of a rod, having attached to it a cord with a running noose, which they gradually slip over the head of the animal, and thus secure their prey.

### Genus VI. Draco. FLYING DRAGONS.

The extraordinary reptiles comprehended under this name, differ from all the other oviparous quadrupeds, in having a membranous expansion resembling a wing, supported by bony rays, and capable of being folded and unfolded, extending from the flanks along each side of the body to the shoulders. In other respects they resemble the guanas, having, like them, a crest along the back and part of the tail, and an inflated membrane below the throat. Their tail is, however, proportionally longer, smaller, and more cylindrical, and their limbs more delicately formed. Naturalists of the present day reckon three species, which Daudin has distinguished by the following names and characters:

*Species* 1. *Draco lineatus.* Radiated flying dragon. Body beautifully variegated with blue and grey above; wings brown, longitudinally streaked with white.

*Le Dragon rayé*, Daud. iii. p. 298.

2. *D. viridis.* Green flying D. Body green, rather scaly; wings grey, transversely marked with four brown bands, and connected with the thighs. See Plate CCXCVI. Fig. 8.

*Le D. verd*, Daud. iii. p. 301. pl. xli.

*Draco volans*, Linn. a Gmel. p. 1056.

*Le Dragon*, Lacepede, vol. ii. part ii. art. 53.

3. *D. fuscus.* Brown dragon. Body brown, paler beneath, scarcely scaly; wings brown.

*Le D. brun*, Daud. iii. p. 307.

These animals so far resemble each other in habits, manners, and habitation, that it is unnecessary to describe each species. They are usually of small size, seldom exceeding eight inches in length.

From this small size, and the membranous wings with which they are furnished, they readily support themselves for some time in the air, though their flight seldom extends beyond thirty paces, darting from tree to tree in the manner of the flying squirrels; animals which they much resemble, as well in their motions as in their manner of life. They are supported chiefly by insects, which they sometimes take while on their flight. Flying dragons are found in Asia, Africa, and America, especially in the island of Java.

We need scarcely remark, that the fantastic animals described by the older writers of natural history, under the name of dragons, are mere creatures of the imagination; though it may be proper to observe, that specimens are not unfrequently met with, in cabinets of animals, that nearly resemble the figures given by those writers. It is now known that these specimens are artificial, and are formed by designing people, who make a trade of selling natural curiosities, by dressing up small ray fish, so as to resemble the fabulous dragons.

### Genus VII. Agama. AGAMAS.

The species now ranked under this name had generally been regarded as guanas, or stellios, from which Daudin distinguishes them by the following characters: Body oblong, more or less thick, entirely covered with small rhomboidal scales, that are almost always carinated and reticulated together; tail in most instances cylindrical, but in a few compressed; throat capable of being inflated; tongue short, thick, a little cleft at its tip; head thick, callous, generally set with spines at the back part, and covered with numerous small rhomboidal scales; feet long and thin, having each five slender toes furnished with claws. There are twenty-five species, arranged under five Sections.

#### Sect. 1. *Agamas having a compressed Tail.*

*Species* 1. *Agama superciliosa.* Supercilious Agama. Body of a pitchy black; back and tail crested above; occiput callous and spinous; scales of the body rhomboid and carinated.

*L'Agame sourcilleux*, Daud. iii. p. 336.

*Lacerta superciliosa*, Linn. a Gmel. p. 1063.

*Le Sourcilleux*, Lacepede, vol. i. part ii. art. 7.

*Fringed lizard*, Shaw.

2. *A scutata.* Fork-headed A. Tail a little compressed, of the length of the body; a serrated crest on the back and tail; occiput callous and two forked.

*L'A. occiput fourchu*, Daud. iii. p. 345.

*Lacerta scutata*, Linn. a Gmel. p. 1063.

*Shielded lizard*, Shaw.

*La tete fourchue*, Lacepede, vol. i. part ii. art. 8.

3. *A. atra.* Black A. Occiput very spinous; body of a blackish squalid brown above, with a longitudinal yellowish band along the back; belly and throat bluish; tail a little compressed.

*L'Agame sombre*, Daud. iii. p. 349.

4. *A. fasciata.* Banded A. Tail compressed, thrice as long as the body; colour blue, paler below, with pale spots on the neck, and four transverse pale blue bands, of which the second is the shortest, on the back.

*L'A. à bandes de l'Inde*, Daud. iii. p. 352.

#### Section II. *Agamas properly so called.*

Body slender, without tubercles; tail cylindrical.

5 *A. colonorum.* Common Agama. Tail long; upper part of the neck and back part of the head spinous, with the scales of the occiput reversed; a small dorsal pectinated crest; colour a pale greenish blue.

*L'A. des colons*, Daud. iii. p. 356.

*Lacerta agama*, Linn. a Gmel. p. 1064.

*L'Agame*, Lacep. i. part ii. art. 17.

6. *A. calotes.* Galeot A. Blue; tail long; fore part

of the back and back part of the head furnished with a small crest. See Plate CCXCVII. Fig. 9.

*L'A. galeote*, Daud. iii. p. 361. pl. xliii.
*Lacerta calotes*, Linn. a Gmelin, p. 1063.
*Galeot lizard*, Shaw.
*L'A. galeote*, Lacepede, i. part ii. art. 15.

7. *A. Umbra.* Clouded A. Tail long; occiput callous and spinous; back five streaked; a black spot on the throat.

*L'A. umbre*, Daud. iii. p. 375.
*Lacerta umbra*, Linn. a Gmel. p. 1064.
*Clouded lizard*, Shaw.
*L'Umbre*, Lacepede, ii. part ii. art. 30.

8. *A. undulata.* Undulated A. Ash brown above, irregularly marked with transverse bands or waves; bluish below, with a large whitish cross.

*L'A. ondulé*, Daud. p. 384.

9. *A. angulata.* Angled A. Head wrinkled above, and almost naked; scales of the back rhomboidal and carinated, those of the belly smooth; two large round scales below the throat; tail long and hexagonal.

*L'A. hexagone*, Daud. iii. p. 389.
*Lacerta angulata*, Linn. a Gmel. 1061.
*Angulated lizard*, Shaw.
*L'Hexagone*, Lacepede, i. part ii. art. 22.

10. *A. muricata.* Muricated A. Body longitudinally streaked with pointed carinated scales; tail striated, barred, twice as long as the body; occiput callous and spinous.

*L'A. hérissé de la Nouvelle Hollande*, Daud. iii. p. 391.
*Muricated lizard.* White's *Voyage to New South Wales*, p. 244.

11. *A. versicolor.* Harlequin A. Back marked on each side with a longitudinal white line; body of a clear blue, with transverse brown bands upon the back; tail twice as long as the body.

*L'A. Arlequiné*, Daud. iii. p. 395, plate xliv.

12. *A. flavigularis.* Yellow-throated A. Grey, reddish above, with a yellow throat; tail once and a half as long as the body, a short longitudinal white line upon each flank.

*L'A. a gorge safranée*, Daud. iii. p. 398.

13. *A. rosacauda.* Rose-tailed A. Grey, pale below; tail of a rose colour, $1\frac{1}{2}$ the length of the body.

*L'A. rose-queue*, Daud. iii. p. 400.

14. *A. aspera.* Rough A. Head smooth and reddish above; body and tail beset with pointed scales, marbled with transverse shades of reddish-brown and white.

*L'A. rude*, Daud. iii. p. 402.

15. *A. stellaris.* Starred A. Body and tail furnished above with a toothed crest, with numerous white starry points on the back and on each side.

*L'A. etoilé*, Daud. iii. p. 404.

### Section III. *Orbicular Agamas or Tapays.*

Body a little depressed, and beset here and there with small rounded or pointed tubercles.

16. *A. orbicularis.* Orbicular A. Body orbicular and rough, variegated above with brown; head like that of a toad; feet yellow below; tail of moderate length.

*L'A. orbiculaire*, Daud. iii. p. 406. plate xlv. fig. 1.
*Lacerta orbicularis*, Linn. a Gmel. p. 1061.
*Le Tapaye*, Lacepede, vol. ii. part ii. art. 37.
*Orbicular lizard*, Shaw.

17. *A. Gemmata.* Gemmed A. Body marked with six longitudinal rows of four-sided pointed scales, with brownish transverse angular bands upon the back.

*L'A. à pierreries*, Daud. iii. p. 410.

18. *A. plica.* Plated A. Tail long; occiput callous, palpebræ excoriated above; neck tuberculated at the sides, and plated below.

*L'A. plissé*, Daud. iii. p. 412.
*Lacerta plica*, Linn. a Gmel. p. 1074.
*Le plissé*, Lacepede, ii. part ii. art 31.

19. *A. paraguensis.* Paraguay A. Tongue round and thick; head obtuse; a longitudinal brown band upon the back, with a triangular brown spot on each side of the tail.

*L'A. du Paraguay*, Daud. iii. p. 414.

20. *A. helioscopa.* Stargazing A. Tail imbricated, thick at the base, and sharp at the tip; head thick and callous, spinous at the back part; neck contracted, marked with a transverse fold below; tail scarlet below.

*L'A helioscopa*, Daud. iii. p. 419.
*Lacerta helioscopa*, Linn. a Gmel. p. 1074.

21. *A. uralensis.* Uralian A. Head roundish, neck plated below; back of a livid ash-colour, wrinkled, and a little rough; tail the length of the body, black at the tip, and six-banded.

*L'A. raboteux de l'oural.* Daud. iii. p. 422.
*Lacerta uralensis*, Linn. a Gmel. p. 1073.

22. *A. guttata.* Dotted A. Head roundish; body smooth, blue above, with round white dots; belly whitish; tail longer than the body, black at its tip, with four black opposite spots towards its base.

*L'A. a goutelettes*, Daud. iii. p. 426.
*Lacerta guttata*, Linn. a Gmel. p. 1078.

23. *A. aurita.* Eared A. Angles of the mouth dilated on each side into a semi-orbicular dentated crest.

*L'A. a oreilles*, Daud. iii. p. 429. plate xlv. fig. 2.
*Lacerta aurita*, Linn. a Gmel. p. 1073.

### Sect. IV. *Lizard Agamas.*

Plates on the head, and a row of granular pores under each thigh.

24. *A. marmorata.* Marbled A. Throat inflated; head covered with numerous plates, colour brownish-bay, with transverse dark bands and green shades; tail very long.

*L'A. marbré de Surinam*, Daud. iii. p. 433.
*Lacerta marmorata*, Linn. a Gmel. p. 1065.
*Marbled lizard*, Shaw.
*Le marbré*, Lacepede, ii. part ii. art. 39. plate ii.

### Sect. V. *Agamas with prehensile Tails.*

25. *A. prehensilis.* Prehensile A. Four transverse black bands on each flank; belly brown, with black and white shades; three black bands upon the cheeks; tail prehensile, scarcely longer than the body.

*L'A. a queue prenante*, Daud. iii. p. 440.

## Genus VIII. Stellio. STELLIOS.

Body oblong, thick, entirely covered with small scales, regularly disposed transversely; tongue thick, short, and a little cleft at the tip; head broad, rather short, covered above with numerous scales or plates; throat capable of slight inflation; tail compressed, surrounded with transverse rows of large carinated pointed scales; feet strong, furnished each with five separate toes, tipt with claws.

This singular tribe of reptiles, which, in the form of their bodies and the tubercles with which they are often covered, bear some resemblance to the toads. are found only in the hottest parts of Africa and America. They hide themselves during the day below stones, and in the crevices of old buildings, and leave these retreats at the approach of night. They prefer dry situations, and live chiefly on insects.

Daudin has characterised nine species, which he arranges under three Sections, as follows.

Sect. I. *Cordyli.*

Plates upon the head, body, and tail, versicillated and spinous.

*Species* 1. *Stellio cordylus.* Cordyle S. Head plated above, body and tail covered with pointed carinated scales, disposed in whirls.

*Le Stellion Cordyle*, Daud. iv. p. 8.

*Lacerta Cordylus*, Linn. a Gmel. p. 1060.

*Le Cordyle*, Lacepede, i. part ii. art. 21.

Sect. II. *True Stellios.*

Head covered above with small scales, with some scattered transverse bands of large scales upon the body.

2. *S. Vulgaris.* Common S. Body covered with small scales, with a few transverse bands of larger scales upon the back; scales of the tail a little elongated.

*Le S. proprement dit*, Daud. iv. p. 16.

*Lacerta Stellio*, Linn. a Gmel. p. 1060.

*Le Stellion*, Lacepede, ii. part ii. art. 33.

*Rough lizard*, Shaw.

3. *S. Platurus.* Broad tailed S. Tail flat, broadest in the middle, spinous at its edges; occiput and back tuberculated and spinous; muzzle slender; colour brownish-grey.

*Le S. a queue plate de la Nouvelle Hollande*, Daud. iv. p. 24.

*Broad tailed lizard.* White's *Voy. to New South Wales*, p. 246.

Sect. III. *Bastard Stellios.*

Numerous very small scales on the upper part of the head and body.

4. *S. quetz-paleo.* Quetz-paleo S. Pale grey; body a little scaly and granulated; tail the length of the body, with elongated scales, each thigh furnished below with a row of fifteen pores.

*Le S. quetz-paleo.* Daud. iv. p. 26.

5. *S. Spinipes.* Spinefooted S. Body of a bright green, covered with minute scales, spinous at the sides; upper part of the feet covered with round sharp scales; pores below the thighs; tail a little elongated.

*Le S. Spinipède*, Daud. iv. p. 31.

6. *S. azureus.* Azure S. Body of a light azure colour, without spots, and slender; tail elongated, and surrounded with 35 or 36 spinous whirls.

*Le S. Azuré de l'Amérique meridionale*, Daud. iv. p. 36. pl. xlvi.

7. *S. brevicauda.* Short tailed S. Colour light blue, with transverse bands of a darker blue, and a star-like spot upon the forehead; tail a little depressed and short. See Plate CCXCVII. Fig. 10.

*Le S. courte queue*, Daud. iv. p. 40. pl. xlvii.

8. *S. Pelluma.* Pelluma S. Upper part of the body variegated with green, yellow, blue, and black; lower part with green and yellow; tail the length of the body.

*Le S. pelluma du Chili*, Daud. iv. p. 46.

*Lacerta pelluma*, Linn. a Gmel. p. 1060.

*Pelluma lizard.* Shaw.

9. *S. niger.* Black S. Colour black, with a double broad white spot on each side of the neck.

*Le S. négre*, Daud. iv. p. 48.

Genus IX. Chameleo. CHAMELEONS.

The head short and pretty thick, covered on its surface with smooth five-sided or six-sided scales; nose generally obtuse; eyes covered with a granular membrane perforated in the middle; tongue long and cylindrical, terminating in a glutinous tubercle, and very extensile; tympanum of the ear very apparent; throat capable of inflation into a compressed pouch; body elongated, compressed, capable of considerable inflation, covered with small scaly tubercles, irregularly disposed at a distance from each other; back sharp, and often furnished with a crest formed by small prominent or pointed scales; tail at least as long as the body, covered with a granular scaly skin, capable of being rolled in a spiral form round an object; feet furnished each with five toes, terminating in claws, and united two together and three together.

*Species* 1. *Chameleo vulgaris.* Common chameleon, brownish-grey, with a spiny crest upon the back and throat; occiput pyramidal, four-sided, with prominent tubercles under the skin of the back. See Plate CCXCVII. Fig. 11.

*Le Chaméléon ordinaire*, Daud. iv. p. 181.

*Lacerta chamæleon.* Linn. a Gmel. p. 1069. See Shaw's *Gen. Zool.* iii. pl. lxxvi.

*Le Caméléon*, Lacepede, ii. part ii. art. 26.

2. *C. Senegalensis.* Senegal C. Yellowish ash colour, shaded above with blackish; an acute slender crest upon the back, and a serrated crest upon the belly; occiput furnished with a triangular eminence.

*Le C. à ventre dentelée en scie du Senegal*, Daud. iv. p. 203.

3. *C. pumilus.* Dwarf C. Light blue, with two yellowish longitudinal lines on each side of the body; throat fringed below.

*Le C. nain du Cap de bonne Esperance*, Daud. iv. p. 212. pl. liii.

*Lacerta pumila.* Linn. a Gmel. p. 1069.

4. *C. bifidus.* Two-forked C. Fore part of the muzzle prominent and two-forked, with each division long and compressed.

*Le C. nez fourchu de l'Inde*, Daud. iv. p. 217. pl. liv. See *Phil. Trans.* vol. lviii.

The chameleons are remarkable both for peculiarity of structure and singularity of manners; and the first and best known species has long been celebrated, both in ancient and modern times, for the variety of colours which it assumes on different occasions. Their skin is remarkably thin and delicate, and is so loose and dilatable, especially about the belly, as to admit of considerable inflation when the animals expand their ample lungs by a long and deep inspiration. Their eyes are remarkable, both for the membrane that covers them, and for the ease with which they are directed at the same time towards different objects. The peculiar structure of their feet, and their prehensile tails, serve to give them a surer hold of the branches of trees in which they generally live, and thus secure them against the attacks of serpents, by whom they are eagerly sought after, while their long extensile and glutinous tongue enables them more easily to catch the insects which form their natural food. From the smallness of these insects, and the long abstinence which the chameleons are able to sustain, it was long believed that these animals lived upon air: a vulgar error, which has given birth to many a pretty expression among our poets. It has also been supposed, that chameleons assume the colour of any object on which they are laid. This is so far true, that if the object be green of any shade, as green is the prevailing colour of the chameleon, and as it passes through various shades of this colour, when pleased or angry, hungry or satiated, it acquires, in the course of the experiment, a shade very near that of the grass or cloth on which it is laid. It never becomes quite blue or quite white, though it often verges upon these colours; and sometimes the shade of green is so dark, that a hasty observer might call it black.

Attempts have been made to account for the changes of colour in the chameleon, by the remark, that the blood of this animal is of a violet blue, while the natural colour of the skin is yellow; hence, when the skin is most transparent, and the animal in greatest vigour, the shade of green is darkest, or assumes most of the blue tinge, while, when the skin is least stretched, and the circulation languid, the colour becomes paler, and verges towards yellow-white, or even brown.

Chameleons are found chiefly in the tropical climates of the old continent, especially in Egypt and other parts of Africa. They are generally of diminutive size, the largest not exceeding two feet, from the muzzle to the tip of the tail; of which the tail occupies one-half.

### Genus X. Gecko. GECKOS.

The animals of this tribe are not so unsightly in their external appearance as they are disgusting in their manners, and the noxious fluid which they secrete. Their head is pretty thick, especially at the articulation of the jaws, where it is bordered with small plates, while the surface of the head is covered with small rounded prominent scales; the muzzle is taper; the tongue thick, flat, slightly cleft at its tip, and glutinous, but not extensile; the eyes resemble those of the chameleons, but the external opening of the ears is less apparent, and the throat is susceptible of slight inflation. The body is long and thin, a little depressed, and covered with very small prominent scales; the tail is generally cylindrical, but in a few species flattened; the feet have each five broad toes, flattened along their margins, covered on their inferior surface with small transverse imbricated scales, concealing glandular pores, from which exudes a very corrosive fluid. Each toe is tipped with a small crooked claw.

The geckos are found in South America, in Africa, and the East Indies. They live about walls and in trees, feed chiefly on insects, and have so little dread of mankind, as familiarly to enter their houses.

There are 15 species, arranged under three Sections.

#### Section I. *Geckos.*

Geckos, properly so called, having the five toes distinct, or a little palmated at their base, the tail cylindrical, and the body smooth.

*Species* 1. *Gecko Ægyptiacus.* Egyptian or common gecko. Light ash-grey; tail for the most part having six broad rings at its base; body rather swollen, and a little flattened. See Plate CCXCVII. Fig. 12.

*Le Gecko ordinaire*, Daud. iv. p. 107.

*Lacerta gecko*, Linn. a Gmel. p. 1068.

*Common gecko, lizard*, Shaw.

*Le Gecko*, Lacepede, ii. part ii. art. 48.

A very curious structure has lately been detected in the foot of this animal by Sir Everard Home, Bart. Sir Joseph Banks had often observed at Batavia, that the Gecko comes out in the evening from the roofs of the houses, and walks down the smooth hard polished chunam walls in search of flies; and it occurred to Sir Everard Home, that this must be done by a contrivance like that of the *Echineis remora*, or sucking fish. Having procured from Sir Joseph a large specimen weighing 5¾ oz. he was enabled to ascertain the peculiar mechanism by which the feet of the animal can keep hold of a smooth surface. Plate CCXCV. Figs. 18, 19. The Gecko has five toes, and at the end of each, except the thumb, is a very sharp curved claw. On the under surface of each toe are 16 transverse slits, leading to as many cavities, or pockets, whose depth is nearly equal to the length of the slit which forms the orifice: they all open forwards, and the external edge of each opening is serrated like a small-toothed comb. The cavities, pockets, and serrated edges, are covered with a cuticle. A large oval muscle moves the claw of each toe; and from the tendons of these large muscles, two sets of smaller muscles originate, one pair of which is lost upon the posterior surface of each of the cavities that lie immediately over them. The large muscles draw down the claws, and necessarily stretch the small muscles. When the small muscles contract, they open the orifices of the cavities, and turn down their serrated edge upon the surface on which the animal stands. By this means vacua are formed, and the animal adheres to the surface by the pressure of the atmosphere. See *Phil. Trans.* 1816, p. 149. and page 404, col. 2. of this article.

2. *G. lævis.* Smooth G. Ash grey, all the scales very minute, inside of the thighs not porous; tail of moderate length, simple at the base; tips of the toes triangular.

*Le G. lisse d'Amérique*, Daud. iv. p. 112.

3. *G. spinicauda.* Spine-tailed G. Body smooth; tail nearly the same length as the body, thick, and ringed at the base; rings beset with spines on each side.

*Le G. a queue épineuse*, Daud. iv. p. 115.

4. *G. guttatus.* Dotted G. Pale red above, with small round whitish spots disposed in rows; numerous square scales upon the tail.

*Le G. a gouttelettes blanches*, Daud. iv. p. 122. pl. xlix.

5. *G. Surinamensis.* Surinam G. Tail as long as the body, with brown bands, a yellowish band bordered with brown running from the eyes to the thighs; back marbled with little brown spots.

*Le G. de Surinam*, Daud. iv. p. 126.

6. *G. porphyreus.* Porphyry G. Pale red-brownish above, with numerous small round spots of a paler hue.

*Le G. porphyré*, Daud. iv. p. 130.

7. *G. squalidus.* Squalid G. Tail short; toes carinated above, lamellated below; scales very minute, unequal, and dotted.

*Le G. chagriné*, Daud. iv. p. 134.

8. *G. vittatus.* Banded G. Reddish, with a longitudinal white band running from the occiput, where it is forked, along the back; tail long, marked with white bands.

*Le G. a bandeblanche de l'Inde*, Daud. iv. p. 136. plate l.

*Lacerta vittata*, Linn. a Gmel. p. 1067.

*Forked lizard*, Shaw.

9. *G. rapicauda.* Turnip-tailed G. Dirty brown, with a whitish band, bordered with brown, behind the eyes; tail short, thick, and turbinated at the base, constricted at the anus, pointed at the tip.

*Le G. a queue turbinée*, Daud. iv. p. 141. plate li.

*Lacerta rapicauda*, Linn. a Gmel. p. 1068.

*Turnip-tailed lizard*, Shaw.

#### Sect. II. *Geckots.*

Tail cylindrical; body covered with pointed scales.

10. *G. fascicularis.* Common geckot. Twelve longitudinal rows of acute fasciculated scales on the body; tail short, with two broad rings at its base.

*Le G. fasciculaire*, Daud. iv. p. 144.

*Lacerta mauritanica*, Linn. a Gmel. p. 160.
*Moorish lizard*, Shaw.
*Le Geckotte*, Lacepede, ii. part ii. art. 49.

11. *G. triedrus.* Triangular G. Body covered above with eighteen longitudinal rows of triangular pointed scales; lower part of the tail covered with small transverse plates.
*Le G. a ecailles triédres*, Daud. iv. p. 155.

12. *G. Tuberculosus.* Tuberculated G. Brownish, covered above with scattered, sharp, tuberculated scales, with brown spots upon the back, disposed in pairs.
*Le G. tuberculeux*, Daud. iv. p. 158.

Sect. III. *Flat-tailed Geckots.*

13. *G. fimbriatus.* Fimbriated G. Head, body, and legs flattened at the sides, and bordered with a membranous fringe; tail broad and compressed, with a simple membrane on each side.
*Le G. a tete plâte*, Daud. iv. p. 160. pl. lii.
*La tete plâte*, Lacepede, ii. part ii. art. 50.

14. *G. cristatus.* Crested G. Tail furnished with a pinnatifid membranous crest; feet palmated.
*Le G. a queue cretée*, Daud. iv. p. 167.
*Lacerta caudiverbera*, Linn. a Gmel. p. 1058.
*Flat-tailed lizard*, Shaw.
*Le fouette queue*, Lacepede, i. part ii. art. 4.

15. *G. sarroubea.* Sarroube G. Yellow, spotted with green; fore feet four-toed.
*Le G sarroubé de Madagascar*, Daud. iv. p. 176.
*Le salamandre sarroubé*, Lacep. ii. part ii. art. 58.

## Genus XI. Anolis. ANOLES.

The animals of this genus are nearly allied to those of the last, in the form of their bodies and the structure of their feet, except that, in the latter, only the first joint of the toes are scaly below. The body is covered with fine granular scales; the tongue is not cleft, and is attached to the floor of the mouth; the tail is cylindrical in some species, and compressed in others.

The anoles are inhabitants of America, where they live in dry places much exposed to the sun. Daudin reckons eight species, arranged under two Sections.

Sect. I. *Anoles having the Tail compressed, carinated, and serrated.*

*Species* 1. *Anolis bimaculatus.* Two-spotted A. Bluish green, with a black spot upon each shoulder; back flattened and serrated. See Plate CCXCVII. Fig. 13.
*L'Anolis bimaculé*, Daud. iv. p. 55.
*Lacerta bimaculata*, Linn. a Gmel. p. 1059.
*Le Bimaculé*, Lacepede, i. part ii. art. 10.
*Pennsylvanian lizard*, Shaw.

2. *A. carbonarius.* Charcoal coloured A. Deep black, with shades of blue; throat yellow; toes broadest at their tips.
*L'A. charbonnier*, Daud. iv. p. 64.

3. *A. lineatus.* Striped A. Body marked on each side with two longitudinal rows of oblong black linear spots.
*L'A. rayé*, Daud. iv. p. 66. plate. xlviii. fig. 1.

Sect. II. *Anoles having a cylindrical Tail, articulated, but not carinated.*

4. *A. Bullaris.* Red-throated A. Greenish or reddish, with a black spot on the temple.
*L'A. roquet*, Daud. iv. p. 69.
*Lacerta bullaris*, Linn. a Gmel. p. 1075.
*Le roquet*, Lacepede, ii. part ii. art. 40. pl. iv. fig. 1.

5. *A. punctatus.* Dotted A. Blue above, with white dots, and a black longitudinal line upon the back; sides dotted with black.
*L'A. a points blancs de l'Amerique meridionale*, Daud. iv. p. 84. pl. xlviii. fig. 2.
*Lacerta punctata*, Linn. a Gmel. p. 1076.
*Dotted lizard*, Shaw, *Gen. Zool.* vol. iii.

6. *A. podagricus.* Gouty A. Greenish above, yellowish below, with marginated nostrils, and the joints of the toes flattened.
*L'A. goutteux*, Daud. iv. p. 87.

7. *A. auratus.* Gilded A. A longitudinal white line edged with brown, running from the eyes along each side of the body; toes slender.
*L'A doré*, Daud. iv. p. 89.

8. *A. sputator.* Spitting A. Tail round, and of moderate length, covered below with a longitudinal row of plates; toes truncated; body ash colour, with transverse white bands, bordered with liver colour.
*L'A. sputateur*, Daud. iv. p. 99.
*Lacerta sputator*, Linn. a Gmel. p. 1076.
*Spitting lizard*, Shaw, *Gen. Zool.* vol. iii.

## Genus XII. Lacerta. LIZARDS.

In the numerous tribe of lizards, properly so called, the body is covered on its upper part with very small hexagonal or rounded scales, disposed in numerous transverse bands, and below with small smooth square plates, disposed in longitudinal rows. The head resembles an oblong pyramid, with four sides covered above and on the sides with smooth plates. The tongue is forked, and capable of being thrust far out of the mouth. The opening to the ear is oval or oblong, and very apparent. The tail is at least as long as the body, quite cylindrical, composed of jointed rings, and has no upper crest. All the feet are nearly of equal length, and under each thigh there is a row of small, rough, porous, scaly tubercles. Each foot has five toes, completely separate, thin, and terminated by small crooked claws. Many of the species inhabit woody situations, and seek their food among the foliage, or in the underwood. This food consists chiefly of insects. Others live about ruinous buildings, or even approach the dwellings of mankind, and feed partly on insects, and partly on fruits and vegetables. A few have their natural habitation in marshes, ponds, or lakes, and prey upon the small animals which inhabit them.

The lizards are in general lively and active, and, on the whole, form the most pleasing of all the Saurian tribes. They are innocent in their manners; cheerful in their movements; and many of them, from their agreeable form and variety of colour, constitute very pleasing features in a group of natural objects.

Most of them are natives of the warmer climates; but more of this tribe than of any other of the Saurian order, are indigenous in the temperate countries of Europe. There are about 32 species, which Daudin distributes under seven Sections.

Sect. I. *Ameiva Lizards.*

No scaly collar on the neck; tail entirely cylindrical and verticillated.

*Species* 1. *Lacerta ameiva.* Ameiva lizard. Of a bright blue colour, with four longitudinal rows of round whitish spots on each side; neck transversely plaited below.

*Le lezard ameiva*, Daud. iii. p. 96.
*L'Ameiva*, Lacepede, vol. i. part ii. art 23.
*Lacerta ameiva*. Linn. a Gmelin, p. 1070.
*Blue lizard*, Shaw, *Gen. Zool.* vol. iii.

2. *L. litterata*. Lettered L. Bluish green, variegated above with oblong black spots, and transverse black bands, dotted with white on each side; neck transversely plaited below.
*Le L. verd a traites noires d'Allemagne*, Daud. iii. p. 106.

3. *L. graphica*. Graphic L. Bluish-green, marked with black points and characters, with a longitudinal fold on each side of the body, without white eye-like spots; neck transversely plaited below.
*Le L. graphique*, Daud. iii. p. 112.

4. *L. argus*. Argus L. Blue; back marked with blue, eyes disposed in transverse rows, with a longitudinal fold on each side of the body; tail transversely plaited below.
*Le L. argus d'Amerique*, Daud. iii. p. 117.

5. *L. gutturosa*. Swollen throated L. Sea-green, throat and neck swollen; red spots scattered over the body, especially on each side.
*Le L. verd u points rouges*, Daud. iii. p. 119.

6. *L. erythrocephala*. Red-headed L. Back dark green, with transverse undulated brown bands; throat white; breast black; sides marked with brown bands; belly striped longitudinally with black, blue, and white; head red; tail short.
*Le L. á tête rouge*, Daud. iii. p. 122.
*La tete rouge*, Lacepede, vol. i. part ii. art. 20.

SECT. II. *Green Lizards.*

Green lizards, having a scaly collar round the neck, and a verticillated tail.

7. *L. oscellata*. Eyed L. Black above, with lines and eye-like spots of a light green; light yellow below, without spots.
*Le grand L. verd ocellé du midi de l'Europe*, Daud. iii. p. 125. pl. xxxiii.
*Le L. verd*, Lacepede, i. part ii. art. 19. pl. xv. fig. 1.

8. *L. viridis*. Green L. Bright green, marked above with very numerous black or brown points; light green below without spots.
*Le L. piqueté d'Europe*, Daud. iii. p. 144. pl. xxxix.

9. *L. jamaicensis*. Jamaica L. Back reticulated with pale brown, with yellow dots; a double longitudinal row of ovate blue spots along each side; tail long.
*Le L. verd de la Jamaique*, Daud. iii. p. 149.

10. *L. bilineata*. Two-lined L. Back marked with two longitudinal white lines, edged above with brown; a longitudinal row of brown spots, and white points on each side of the body, and a long tail.
*Le L. verd a deux raies*, Daud. iii. p. 151. pl. xxxv. fig. 1.

11. *L. stirpium*. Copse L. Bright green, spotted with black; back and tail grey, with a brown interrupted line along the back; a double row of black eye-like spots along each side, and a dotted belly.
*Le L. de souches*, Daud. iii. p. 155. pl. xxiv. fig. 2.

12. *L. viridula*. Greenish L. Bright green above; yellow below; tail three times the length of the body, and black at the tip, with an orange-coloured spot on the occiput and neck.
*Le L. verdelet de Panama*, Daud. iii. p. 165.

13. *L. tiliguerta*. Tiligurta L. Tail double the length of the body; belly marked with eighty plates.
*Le L. tiligurta*, Daud. iii. p. 167.
*Lacerta tiligurta*, Linn. a Gmelin, p. 1070.

14. *L. dumetorum*. Wood L. Bright green, with the neck and belly of a bright steel colour; feet black, and the collar of the neck serrated, and of a violet colour.
*Le L. des boissons de Surinam*, Daud. iii. p. 172.

SECT. III. *Ribbon Lizards.*

Having a collar on the neck, and several longitudinal white parallel lines along the upper part of the body.

15. *L. lemniscata*. Laced L. Nine white longitudinal lines upon the back and sides; long tail, blue on the upper part; thighs spotted with white, and the middle dorsal line two-forked next the head. See Plate CCXCVII. Fig. 14.
*Le L. Galonné*, Daud. iii. p. 175. pl. xxxvi. fig. 1. Lacepede, i. part ii. art. 25.
*Lacerta lemniscata*. Linn. a Gmelin, p. 1075.

16. *L. sexlineata*. Six-striped L. Blackish brown above, with six longitudinal white lines upon the back, with another short white line extending from the eyes over the shoulders; tail twice as long as the body, and thighs without spots.
*Le L. a six raies*, Daud. iii. p. 183.
*Lacerta sexlineata*, Linn. a Gmelin. p. 1074.
*Le lion*. Lacepede, i. part ii. art. 24.

17. *L. bosquiana*. Bosquian L. Bright blue above, with nine white longitudinal lines, with intermediate dots upon the back and sides, the middle line being short and undivided; tail twice as long as the body; thighs spotted with white.
*Le L bosquien*, Daud. iii. p. 188. pl. xxxvi. fig. 2.

18. *L. cæruleocephala*. Blue-headed L. Head blue, with a white longitudinal line along the middle of the back; two yellow parallel lines on each side; white dots upon the thighs, and tail twice the length of the body.
*Le L a tête bleue*, Daud. iii. p. 19.

19 *La teyou*. Teyou L. Upper part of the head green; back violet colour, with one green line and six white ones; throat and belly of a silvery white.
*Le L. teyou verd*, Daud. iii. p. 195.

20. *L. deserti*. Desert L. Tail the length of the body; back black, with six white interrupted longitudinal lines; belly white without spots.
*Le L. du désert*, Daud. iii. p. 199.
*Lacerta deserti*, Linn. a Gmelin, p. 1076.

21. *L. velox*. Swift L. Body ash-coloured above, variegated with brown dots, and five longitudinal streaks of a lighter colour; sides spotted with black and blue.
*Le L. veloce*, Daud. iii. p. 202.
*Lacerta velox*, Linn. a Gmelin. p. 1072.

SECT. IV. *Spotted Lizards.*

22. *L. lepida*. Languedoc L. Body greenish blue above, with nine or ten transverse black bands, spotted with small round white eyes; belly whitish; tail scarcely longer than the body.
*Le L. gentil du Languedoc*, Daud. iii. p. 204. pl. xxxvii. fig. 1.

23. *L. maculata*. Spotted L. Blackish blue above, with a few round spots of a pale violet; belly whitish; tail once and a half as long again as the body.
*Le L. tacheté d'Espagne*, Daud. iii. p. 208. pl. xxxvii. fig. 2.

SECT. V. *Grey Lizards.*

24. *L. agilis*. Agile L. Ash coloured above, whitish

below; back marked with a longitudinal dotted brown line, and a subreticulated brown longitudinal stroke, edged with paler colour, on each side of the body.

*Le L. gris des murailles*, Daud. iii. p. 211. pl. xxxviii. fig. 1.

25. *L. brongniardi.* Brongniardian L. Bluish grey, irregularly marbled on the back with black spots, and with three longitudinal lines of black spots and dots on each side.

*Le L. brongniardien*, Daud. iii. p. 221.

26. *L. Sericea.* Silky L. Brownish above, shaded with glossy green and blue; pale green below; tail twice as long as the body, and a little streaked.

*Le L. soyeux*, Daud. iii. p. 224.

27. *L. laurentii.* Laurentian L. Ash brown above, every where spotted, with the spots upon the back obscure, those on the sides disposed in a triple longitudinal row.

*Le L. de Laurenti*, Daud. iii. p. 227.

28. *L. arenicola.* Sand L. Brownish grey, paler, without spots below, with a row of brown spots upon the back, and a double series of brown eyes dotted with white, and another single row of white dots on each side.

*Le L. arénicole*, Daud. iii. p. 230. pl. xxxviii. fig. 2.

29. *L. fusca.* Brown L. Dark brown, with a longitudinal row of obscure spots on each side; belly paler.

*Le L. brun*, Daud. iii. p. 237.

30. *L. arguta.* Sharp-snouted L. Tail short and verticillated, thick at the base. and very sharp at the tip; a remarkable double plate under the neck; general colour sea green, with numerous transverse black bands; belly white.

*Le L. a museau pointue*, Daud. iii p. 240.

*Lacerta arguta*, Linn. a Gmel. p. 1072.

### Sect. VI. *Dracenoid Lizards.*

Having two scaly folds under the neck, and a cylindrical tail verticillated at its proximal, and reticulated at its distal, half.

31. *L. quinquelineata.* Five-streaked L. Bluish, with five longitudinal black lines upon the back, and white spots on each side.

*Le L. a cinq raies*, Daud. iii. p. 243.

### Sect. VI. *Striated Lizards.*

32. *L. striata.* Striated L. Grey, bluish at the sides, with two longitudinal brown lines; scales of the back and belly carinated, and forming longitudinal streaks.

*Le L. strié*, Daud. iii. p. 247.

A considerable degree of uncertainty and ambiguity prevails among writers, respecting the animals called *Lizards*. If, with Linnæus and his followers, we comprehend under this name not only the species just enumerated, but the Tupinambes, the Stellios, the Basilisks, the Guanas, the Geckos, the Chameleons, the Scinks, and the other tribes of the Saurian order, we shall find it comprehend above 150 species; and even curtailed as it is by the modern French naturalists, we see that it is pretty numerous. As it is impossible for us, within the circumscribed limits of an article like the present, to describe even all the most important species, we shall here confine ourselves entirely to a general account of those which are found in the British islands.

Mr Pennant, in the 3d vol. of his *British Zoology*, has described only three species of lizard as belonging to Britain, viz. the *Scaly lizard*, (a variety of *Lacerta agilis*, Linn.) the *Warty lizard*, (*Lacerta palustris*, Linn.) and the *Brown lizard*, (*Lacerta vulgaris*, Linn.) He indeed mentions two more, the *Little brown lizard*, and the *Snake-shaped lizard*, from Ray, but gives nothing on these species from his own observation.

Mr Revett Sheppard, in a paper published in the 7th vol. of the *Linnean Transactions*, has particularized six species as being indigenous in this country, viz. *Lacerta agilis*, scaly or swift lizard; *L. ædura*, swell-tailed L.; *L. anguiformis*, viperine L.; *L. vulgaris*, brown L; *L. palustris*, warty lizard; and *L. maculata*, spotted L. Of these he seems to consider the 2d, 6th, and perhaps the 3d, as new species. His descriptions of these species are sufficiently minute, but he adds nothing respecting their habits or manner of life.

The species most common in this country are the *Warty lizard*, or water newt, and the *Brown lizard*, or common land newt; and of these the former has been most minutely examined. The warty lizard is extremely common in ponds and other stagnant waters. The young lizards continue for some time in an imperfect or larva state, and the perfect animals annually change their skin.*

### Genus XIII. Takydromus. TAKYDROME.

This genus has been formed by Daudin for the purpose of including two species, which differ from the lizards, properly so called, in having a very slender body, which, as well as the extremely long tail, is verticillated, or formed of scaly carinated rings. They have also two small vesicles at the base of each thigh, a long extensile forked tongue, and a remarkable contraction between the head and body. There are two species, viz.

*Species* 1. *Takydromus quadrilineatus.* Four-streaked Takydrome. Brown above, whitish below, with two longitudinal white lines on each side.

*Le Takydrome brun a quatre raies*, Daud. iii. p. 252.

2. *T. sexlineatus.* Six-streaked T. Bright shining blue, with three longitudinal black lines on each side of the body. See Plate CCXCVII. fig. 15.

*Le T. nacre a six raies*, Daud. iii. p. 256. pl. xxxix.

These animals inhabit dry places, and, as their generic name imports, run with great swiftness.

### Genus XIV. Scincus. SCINKS.

Body long and rather thick, entirely covered with elliptical or rounded imbricated scales. Head oblong, covered above with a few plates; tongue rather thick, short, and slightly cleft at its tip. Tail longer or shorter in the different species, covered with scales similar to those of the body. Feet strong, rather short and thin, furnished each with five long, thin, separate toes, terminating in claws.

This is a numerous tribe, comprehending 21 species, which are all natives of warm climates. They are brisk in their motions, and fond of basking in the sunshine. They live in dry stony places, and feed on insects. The species are arranged by Daudin in four sections, as follows.

### Sect. I. *Common Scinks.*

Tail short and conical; colour grey, having generally transverse bands of a deeper colour.

* We have said (p. 393.) that the lizards are innocent reptiles, a position now generally maintained by modern naturalists. We are, however, assured, by an intelligent friend, a clergyman, that when a boy, he had one of his fingers so much affected, in consequence of handling a brown lizard, as to be very nearly in a state of gangrene.

*Species* 1. *Scincus officinalis.* Officinal Scink. Grey, begirt with transverse blackish zones; back a little angular; muzzle short and acute; tail compressed at the tip; margin of the toes serrated.

*Le scinque ordinaire d'Egypt*, Daud. iv. p. 130.

*Lacerta scincus*, Linn. a Gmel. p. 1077.

*Officinal scink*, Shaw, iii. pl. lxxix.

*Le scinque*, Lacep. ii. part ii. art. 34. pl. i. fig 2.

2. *S. galliwasp.* Galley-wasp S. Thick, brown above, with large rounded imbricated scales; muzzle taper, with plates on its upper part; tail thick and short. See Plate CCXCVII. Fig. 16.

*Le gros S. gally wasp de la Jamaique*, Daud. iv. p. 239.

3. *S. gigas.* Giant S. White, with nineteen transverse bands; tail of moderate length.

*Le S. géant*, Daud. iv. p. 244.

4. *S. mabouya.* Mabouya S. Shining ash-brown, with numerous small black spots above each side; sides and belly pale; tail elongated; muzzle prominent.

*Le S. mabouya*, Daud. iv. p. 246. Lacepede, ii. part ii. art. 24. pl. ii. fig. 1.

5. *S. tiligugu.* Tiligugu S. Tail of moderate length, round, and conical; body thick, brown above, thickly set with black dots, whitish below

*Le S. teligugu*, Daud. iv. p. 251.

*Lacerta tiligugu*, Linn. a Gmel. p. 1073.

*Sardinian lizard*, Shaw.

Sect. II. *White-streaked Scinks.*

6. *S. Æneus.* Bronze S. Body slender, of a bronze colour, with a broad longitudinal pale streak upon the back; tail once and a half the length of the body.

*Le S. bronze*, Daud. iv. p. 254.

7. *S. bilineatus.* Two-streaked S. Brownish, with two white longitudinal lines upon the back, with brown spots disposed in rows.

*Le S. a deux raies*, Daud. iv. p. 256.

*Lacerta interpunctata*, Linn. a Gmel. p. 1075.

8. *S. trilineatus.* Three-streaked S. Brown above, with three longitudinal white lines; tail a little longer than the body, with the scales on its back part hexagonal.

*Le S. a trois raies*, Daud. iv. p. 263.

9. *S. quadrilineatus.* Four-streaked S. Tail long and round; fore feet four-toed; hind feet five-toed; with two longitudinal white lines on each side of the body.

*Le S. a quatre raies*, Daud. iv. p. 266.

*Lacerta quadrilineata*, Linn. a Gmel. p. 1076.

*Le quatre raies*, Lacepede, ii. part ii. art. 57.

10. *S. Algira.* Algerine S Scales of the back carinated; two yellow longitudinal lines on each side of the body; tail long and round.

*Le S. Algire*, Daud. iv. p. 269.

*Lacerta Algira*, Linn. a Gmel. p. 1073.

*L'Algire*, Lacep. ii. part ii. art. 32.

11. *S. quinquelineatus.* Five-streaked S. Blackish above, with five longitudinal yellow or white lines upon the back; whitish below; tail of moderate length.

*Le S. a cinq raies*, Daud. iv. p. 272. pl. lv. fig. 1.

*Lacerta quinquelineata*, Linn. a Gmel. p. 1075.

*Le S. strié*, Lacepede, ii. part ii. art. 38.

12. *S. cruentatus.* Bloody S. Tail a little verticillated; ash colour above, scarlet below, with a whitish tip; seven white streaks upon the neck, four of which reach to the tail.

*Le S. ensanglanté de la Siberie*, Daud. iv. p. 278.

*Lacerta cruenta*, Linn. a Gmel. p. 1072.

*Red-tailed lizard*, Shaw.

13. *S. melanurus.* Black-tailed S. Pale ash colour above, marked with seven longitudinal yellowish lines; yellowish below; tail round and black, twice as long as the body.

*Le S. a sept raies et a queue noire de l'Inde*, Daud. iv. p. 280.

14. *S. octolineatus.* Eight-streaked S. Black above, with eight longitudinal whitish lines; whitish below; tail ferruginous, and twice as long as the body.

*Le S. a huit raies de la Nouvelle Hollande*, Daud. iv. p. 285.

*The ribboned lizard*, White's *Voyage to New South Wales*, p. 245.

Sect. III. *Black-streaked Scinks.*

15. *S. sloanii.* Slonian S. Brown above, with four black longitudinal lines, of which the intermediate are shortest; tail a little longer than the body, with rounded imbricated scales on its proximal, and hexagonal verticillated scales on its distal half.

*Le S. sloanien*, Daud. iv. p. 287. pl. lv. fig. 2.

16. *S. schneiderii.* Schneiderian S. Bright brownish above, with a pale longitudinal line on each side, whitish below; tail twice as long as the body.

*Le S. schneidérien*, Daud. iv. p. 291.

*Le Dore*, Lacepede, ii. part ii. art. 36.

17. *S. tristatus.* Sallow S. Back pale brown; sides of a deeper colour, marked with a double pale longitudinal band; tail long and cylindrical.

*Le S. rembruni*, Daud. iv. p. 296.

18. *S. laticeps.* Broad headed S. Head behind the eyes, broad, colour brownish, spotted with black; tail as long as the body, having its distal part covered both above and below with transverse plates.

*Le S. a large tête*, Daud. iv. p. 301.

19. *S. carinatus.* Ridged S. Scales carinated; tail twice as long as the body, covered with scales as in the last species.

*Le S. Caréné*, Daud. iv. p. 304.

Sect. IV. *Ocellated Scinks.*

20. *S. ocellatus.* Eye-spotted S. Ash coloured above, with numerous transverse lines of black scales; yellow in the middle; tail about the length of the body.

*Le S. Ocelle de Chypre et d'Egypt*, Daud. iv. p. 308, pl. lvi.

*Lacerta ocellata.* Linn. a Gmel. 1077.

21. *S. lateralis.* Variegated S. Ash-coloured above, with transverse rows of black spots, with oblong white dots in the middle; black longitudinal lines, dotted below with white upon the sides; tail shorter than the body, and ending suddenly in a point.

*Le S. a bandes laterales*, Daud. iv. p. 314.

Of all these species, the first or Egyptian scink is the most celebrated, both from the high estimation in which it is held by the natives, and for its having been once employed in Europe as a medicine. It is a small animal, seldom exceeding six or seven inches in length, and is of a pale yellowish brown colour. In its manners it is perfectly harmless; and so active in its motions, that it hides itself in the sand in an instant. This species is so numerous in some parts of the East, that several thousands of them have been seen at once in the great court of the temple of the Sun at Balbec. The ground, the walls, and scattered stones of these ruinous buildings, were covered with them, exhibiting a beautiful appearance from their glittering colours, as they lay basking in the sun. See Bruce's *Travels.*

### Genus XV. Seps. EFTS.

Body, neck, and tail very long, thin, cylindrical, and covered with imbricated scales of a roundish or elliptical form. Head thin, oblong, covered above with few scales; tongue rather thick, short, and slightly cleft at its tip. Either four or two feet extremely short, simple, very slender, scaly, furnished with one, two, three, four, or five toes, indistinct, sometimes with claws, sometimes without.

The animals which compose this genus so nearly resemble some of the serpents, as scarcely to be distinguished from them by a casual observer. Indeed, if we except the short and often indistinct feet, and the marks of an external auditory orifice, they possess almost all the other characters of serpents; and accordingly several of them have been ranked among the Ophidian reptiles. In their habitudes and manners, they nearly resemble the scinks, though, from the shortness of their feet, their motions are rather those of snakes than lizards. Daudin enumerates six species, arranged under the two following sections.

#### Sect. I. *Four-footed Efts.*

Species 1. *Seps pentadactylus.* Five-toed Eft. Five toes on each foot, furnished with claws; bay or ash coloured above, with numerous longitudinal brown streaks; whitish below. See Plate CCXCVIII. Fig. 17.

*Le Seps quadrupède pentadactyle*, Daud. iv. p. 325.

*Lacerta serpens*, Linn. a Gmel. p. 1078.

2. *S. tridactylus.* Three-toed E. Feet furnished with three extremely short toes without nails; bay or ash colour above, with four longitudinal brown streaks; paler below.

*Le S. quadrupède tridactyle*, Daud. iv. p. 333. pl. lvii.

3. *S. monodactylus.* One-toed E. Feet extremely thin and short, composed of one toe without claw; tail three times as long as the body; scales subimbricate, and slightly carinated.

*Le S. quadrupède monodactyle*, Daud. iv. p. 342, plate lviii. fig. 1.

*Lacerta anguina*, Linn. a Gmel. p. 1079.

#### Sect. II. *Two-footed Efts.*

4. *S. schneiderii.* Schneiderian S. Whitish above, with a brown line; brown below; feet remote from the *anus*, extremely short, either two or three-toed; toes without claws, and as if arising from a common pedicle.

*Le S. schneiderien*, Daud. iv. p. 348.

5. *S sheltopusik.* Sheltopusik S. Head and body without distinct separation; tail long and round, as well as the body, covered with pale imbricated scales; rudiments of hinder feet only, two-toed, and without claws, at the *anus*.

*Le S. bipède sheltopusik*, Daud. iv. p. 351.

*Lacerta apoda*, Linn. a Gmel. p. 1079.

6. *S. gronovii.* Gronovian E. Dorsal scales dotted with brown; tail smooth at the tip; hinder feet only, very short, with one toe and no claw.

*Le S. gronovien*, Daud. iv. p. 354, pl. lviii. fig. 2.

*Lacerta bipes*, Linn. a Gmel. p. 1079.

### Genus XVI. Chalcides. CHALCIDES.

These reptiles differ from those of the last genus only in the disposition of the scales that cover the body and tail, which, instead of being imbricated as in the seps, are arranged in rings, or verticillated. They inhabit similar situations, and have similar manners. There are four species, of which three are four-footed, and one two-footed.

#### Sect. I. *Four-footed Chalcides.*

*Species* 1. *Chalcides tetradactylus.* Four-toed Chalcides. Scales of the belly hexagonal, with a longitudinal furrow on each side of the body; feet four-toed.

*Le chalcide quadrupède tetradactyle*, Daud. iv. p. 362.

2. *C. tridactylus.* Three-toed C. Feet three-toed, very short, and without claws; tail a little longer than the body. See Plate CCXCVIII. Fig. 18.

*Le Chalcide quadrupède tridactyle*, Daud. iv. p. 367. pl. lviii. fig. 3.

*Le Chalcide*, Lacepede, ii. part. ii. art. 52.

3. *C. monodactylus.* One-toed C. Feet short and very slender, with one toe without claw; tail once and a half the length of the body, and cylindrical.

*Le C. quadrupède monodactyle*, Daud. iv. p. 370.

#### Sect. II. *Two-footed Chalcides.*

4. *C. propus.* Grooved C. Fore feet only with five toes, of which four are clawed and one naked; each side of the body longitudinally furrowed.

*Le C. bipède cannelé*, Daud. iv. p. 372. pl. lviii. fig. 4.

*Bipède cannelé*, Lacepede, ii. p. 325.

Several remains of Saurian reptiles, in a fossil state, have been discovered in the bowels of the earth, particularly the bones of two species or varieties of crocodile, nearly allied to the gavial, but considered by Cuvier as distinct from that species. These remains of crocodiles have been found near Honfleur, Mons, Angers, and Havre in France; at Altorf in Bavaria; at Elston near Newark, in the English county of Nottingham; and on the coast of Whitby in Yorkshire. See *Annales de Museum*, tom. xii. p. 73, and *Phil. Trans.* vol. xxx. p. 963, and vol. l. p. 688, and 786. There have besides been found in the mountains of St Pierre, near Maestricht, some enormous bones of a Saurian reptile, which have occasioned some dispute between MM. St Fond and Cuvier; the former alleging them to be the remains of a gavial crocodile, and the latter arguing, with much plausibility, that although so large, they resemble parts of a Tupinambis rather than of a crocodile.

Parts of a winged reptile, resembling the flying dragon, have also been found in a rock near Manheim. See Daud. in *Hist. Nat. des Reptiles*, tom viii. p. 294.

## Order III. BATRACIAN REPTILE.

The animals of this order resemble those of the two preceding in several respects. Like them, they have all feet, and jaws not formed, of two branches, moveable on each other; and in one part at least of their progress towards maturity, they have all tails. Like the Saurians, their jaws are furnished with teeth, and their larynx is capable of producing sound. On the other hand, they differ from the Chelonians and Saurians, in having a naked body in many instances covered with warts or tubercles; in having the bones soft; in having no external copulative organ in the male, nor any real internal one in the female. Some of them have a sternum, but no ribs; others ribs, but no sternum. Most of the species have four feet in their perfect state. All of them swim, some crawl, and others leap; and the species of one genus attach themselves to objects by round tubercles, terminating their toes. The other characteristic marks have been already mentioned in the first part of this article.

Modern naturalists reckon six genera as belonging to this order, which Dumeril arranges under two subdivisions, as follows:

FAMILY I. *Batracians without Tails.*

GENUS I. HYLA. HYLÆ, or TREE FROGS.

Body slightly compressed, elongated, and smooth. Tongue short and thick; the two fore feet furnished with four toes; the hinder with five; all of them without claws, but terminated by lenticular tubercles.

The tree-frogs, as their name imports, have their habitation in trees, to the leaves of which they adhere by the tubercles on their toes, and where they are often seen leaping from branch to branch, or from leaf to leaf, in search of worms and insects. During winter and early spring they seek the bottom of lakes and rivulets, where, after their hybernation is over, they pair, and where the female lays her eggs. Most of the species are natives of America; but some are common in France, Italy, and other warm European countries.

At the pairing season the male makes a loud shrill croaking noise, and inflates his throat in a remarkable manner. The croaking is said to be particularly loud in the evenings on the approach of rain. It has also been remarked of these animals, that their skin has the power of absorbing water.

There are twenty-eight species, distinguished by the following names and characters.

Species 1. *Hyla viridis*. Green H. Bright green above, with a yellow line on each side, bordered with a blackish shade extending from the nostrils to each flank, and forming a sinuosity above each loin; whitish below.

*La rainette verte*, Daud. viii. p. 23. Lacepede, ii. part iii. art. 14.

*Rana arborea*, Linn. a Gmel. p. 1054.

*Tree-frog*, Shaw.

2. *H. lateralis*. Flank-striped H. Bright green, lighter below, with a straight yellow line upon the sides of the upper lip, body, and limbs.

*La R. flanc-rayée*, Daud. viii. p. 27.

3. *H. bilineata*. Two striped H. Obscure green, with two parallel longitudinal white lines a little arched upon the back.

*La R. bi-rayée*, Daud. viii. p. 30.

4. *H. femoralis*. Thigh-spotted H. Green, with seven or more yellow spots on the upper part of the thighs.

*La R. fémorale*, Daud. viii. p. 32. pl. xciii. fig. 1.

5. *H. squirella*. Yellow-rumped H. Obscure green, with brown spots upon the back, and yellow rump.

*La R. squirelle*, Daud. viii. p. 34. pl. xciii. fig. 2.

6. *H. variegata*. Variegated H. Brown above, with green denticulated spots; limbs marked with transverse green bands; toes flattened.

*La R. bigarré*, Daud. viii. p. 36.

7. *H. intermixta*. Mixed coloured H. Greenish grey above, interspersed with red spots and dots; pale red below.

*La R. mélangée*, Daud. viii. p. 38.

8. *H. bicolor*. Two coloured H. Blue above, yellowish below, with white spots surrounded with violet. See Plate CCXCVIII. Fig. 19.

*La R bicolore*, Daud. viii. p. 40.

*Rana bicolor*. Linn. a Gmel. 1052.

9. *H. cyanea* Blue H. Blue above, reddish clouded ash-colour below; hinder feet palmated.

*La R. bleue de la Nouvelle Hollande*, Daud. viii. p. 43.

*Blue frog*, White's *Voyage to New South Wales*, p. 248. pl. iv.

10. *H. frontalis*. Banded H. Body and legs reddish brown above, with ovate oblong white spots.

*La R. bandeau*, Daud. viii. p. 45.

*Rana leucophylla*, Linn. a Gmel. p. 1055.

11. *H. tinctoria*. Stained H. Body smooth, with two longitudinal and one transverse yellowish lines upon the back.

*La R. a tapirer*, Daud. viii. p. 45.

12. *H. fusca*. Brown H. Brown above; whitish ash-coloured below; entirely without spots.

*La R. brune*, Daud. viii. p. 51.

*La Brune*, Lacepede, ii. part iii. art. 16.

13. *H. rubra*. Red H. Brownish red above, with a double pale line on each side, and rounded spots above the thighs.

*La R. rouge*, Daud. viii. p. 53.

*La rouge*, Lacepede, ii. part iii. art. 20.

14. *H. quadrilineata*. Four-streaked H. Blue or sulphur-yellow above, with a double yellow or whitish line on each side.

*La R. a quatre raies*, Daud. viii. p. 55.

15. *H. aurantiaca*. Orange H. Orange-yellow, with a stain of reddish upon the back.

*La R. orangée*, Daud. viii. p. 57.

*L'Orange squelette*, Lacep. ii. part iii. art. 19.

16. *H. hypochondrialis*. Hypochondrial H. Bluish-grey above, with the sides of the body and limbs yellowish, marked with transverse brown bands; toes cleft.

*La R. hypochondriale*, Daud. viii. p. 60.

17. *H. lactea*. Milky H. Milky white, with a brownish line extending from the nostrils to the eyes; fore-feet semipalmated, hinder palmated.

*La R. lactée*, Daud. viii. p. 62.

18. *H. boans*. Croaking H. Whitish ash-coloured, with broad transverse red and brown streaks; head and mouth broad; hinder-feet semipalmated.

*La R. beuglante*, Daud. viii. p. 64.

*Rana boans*, Linn. a Gmel. p. 1055.

*Croaking frog*. Shaw.

*La Couleur-de-lait*, Lacepede, ii. part iii. art. 17.

19. *H. ocularis*. Eye-streaked H. Silvery-grey, with a lateral brown band extending from each eye to the side; limbs marked with transverse brown bands.

*La R. oculaire*, Daud. viii. p. 68.

20. *H. verrucosa*. Warty H. Uniformly brownish, with a warty back.

*La R. a verrues*. Daud. viii. p. 70.

21. *H. marmorata*. Marbled H. Yellow-ash, marbled with reddish above, dotted with black below; all the feet flat and palmated.

*L. R. marbre*, Daud. viii. p. 71. pl. xciv.

*Le Marbre*, Lacepede, ii. part iii. art. 33.

22. *H. venulosa*. Veined H. Pale reddish, marbled with irregular red streaks or spots, dotted with brown; hinder feet semipalmated.

*La R. réticulaire*, Daud. viii. p. 74.

*Rana venulosa*, Linn. a Gmel. p. 1053.

*La réticulaire*, Lacepede, ii. part iii. art 6.

23. *H. tibiatrix*. Flute H. Yellowish white, interspersed above with reddish dots; hinder feet semipalmated.

*La R. fluteuse*, Daud. viii. p. 76.

24. *H. palmata*. Palmated H. Pale reddish, marbled with reddish brown, with two streaks above the limbs; all the feet palmated.

*La R. patte d'oie*, Daud. viii. p. 80; Lacepede, ii. part iii. art. 7.

25. *H. punctata.* Dotted H. Whitish grey or brownish above, with scattered white dots, and a white line on each side; belly white.

*La R. ponctuée*, Daud. viii. p. 81.

26. *H. blochiana.* Blochian H. Ash-coloured above; whitish below, with an obscure line extending from the nostrils to the ear, and obscure transverse bands upon the thighs.

*La R. blochienne*, Daud. viii. p. 83.

27. *H. melanorabdota.* Black spotted H. Green above, with transverse black spots.

*La R. a taches noires*, Daud. viii. p. 85.

28. *H. surinamensis.* Surinam H. Ash-coloured; marked with ovate red spots above, dotted with black below; all the toes separate.

*La R. de Surinam*, Daud. viii. p. 86.

### Genus II. Rana. COMMON FROGS.

Body thick, a little compressed, elongated, moist, covered with a few small tubercles; generally granulated below, except at the thorax, which is smooth; on each side of the back, above the loins, there is in some species a longitudinal angular fold; tongue short and thick; the fore feet have four separate toes, with the thumb a little larger than the rest in the male; the hinder feet are almost always palmated, and are much longer than the body; the toes are pointed, and have usually a small tubercle under each articulation.

Common frogs cannot climb like the tree-frogs, nor can they be said to walk, their proper motion being that of leaping. They inhabit marshy and boggy places, and the borders of lakes and ponds, into which they frequently leap and swim about, either in search of insects, worms, and the fry of fishes, or for amusement. Here too they pair and lay their eggs.

About the time when the young frogs are come to maturity, it often happens that migrations take place among them from a crowded pond or stream, to one where they are less numerous. On these occasions, it is astonishing what numbers have been seen at once crossing a field or road in their way to their new habitation. According to Mr Rae, two or three acres of ground have been seen nearly covered with them. Frogs arrive at full maturity in about five years, and are supposed to live about twelve or fifteen. The croaking of some species, especially of that called the bull-frog, is remarkably loud; and in some parts of America, where the species abounds, the noise made by their united croaking is heard at a very considerable distance.

Frogs are capable of being rendered familiar, and have become so tame as to eat out of the hand. Some of the species serve for food to man, and most of them become the prey of the larger animals that inhabit marshy situations.

Daudin enumerates sixteen species of Rana, viz.

*Sp.* 1. *Rana esculenta.* Esculent Frog. Green, with black spots, and three longitudinal yellow lines upon the back; belly whitish.

*La Grenouille verte*, Daud. viii. p. 90.

*Rana esculenta*, Linn. a Gmel. p. 1053.

*La Grenouille commune*, Lacepede, ii. part iii. art. 1.

*Gibbous frog*, Pennant, *Brit. Zool.* iii. p. 7.

*Esculent*, or *green frog*, Shaw, iii. pl. xxxi.

2. *R. temporaria.* Common F. Red or brown above, or greenish, with a blackish spot extending from the eye through the opening of the ear.

*La G. rousse a tempes noires*, Daud. viii. p. 94.

*Rana temporaria*, Linn. a Gmel. p. 1053.

*La Rousse*, Lacepede, ii. part iii. art. 2.

*Common frog*, *Brit. Zool.* iii. p. 3. Shaw, iii. pl. xxxix.

3. *R. punctata.* Dotted F. Ash-coloured, dotted with green above; feet marked with transverse bands; toes separate.

*La G. ponctuée*, Daud. viii. p. 100.

4. *R. plicata.* Plaited F. Brown, with the sides double plaited; breast and arms marked with four brown spots; feet separate.

*La G. plissee*, Daud. viii. p. 102.

5. *R. clamata.* Noisy F. Dull ash-coloured, interspersed with black dots; upper lip green; hind feet palmated.

*La G. criarde*, Daud. viii. p. 104.

6. *R. typhonia.* Typhon F. Ash-coloured or reddish, with a few brown spots, and either five or three longitudinal yellow lines upon the back; belly whitish.

*La G. galonnée*, Daud. viii. p. 106. pl. xcv. Lacepede, ii. part iii. art. xii.

*Rana marginata*, Linn. a Gmel. p. 1053.

*Hurricane frog*, Shaw.

7. *R. rubella.* Reddish F. Rusty colour above, with three longitudinal black lines upon the back, and a triangular white spot upon the forehead.

*La G. rougette*, Daud. viii. p. 109.

8. *R. maculata.* Spotted F. Grey, with a square green spot upon the head, and another round one on each shoulder; whitish below, marbled with black.

*La G. tachetée*, Daud. viii. p. 111.

9. *R. pipiens.* Bull F. Very large; dark green above, whitish grey below, interspersed every where with blackish spots.

*La G. mugissante*, Daud. viii. p. 113. Lacepede, ii. part iii. art. 9.

*Rana ocellata*, Linn. a Gmel. p. 1052.

*Bull frog*, Catesby's *Carolina.*

*Rana catesbiana*, Shaw, iii. pl. xxxiii.

10. *R. ocellata.* Eye-spotted F. Very large; reddish brown above, with round brown spots, eyed with yellow on the sides and buttocks.

*La G. ocellée*, Daud. viii. p. 118.

11. *R. halecina.* Pitpit F. Green above, with brown spots eyed with yellow; three longitudinal lines shaded with yellow upon the back; white below.

*La G. hallécine*, Daud. viii. p. 122.

12. *R. tigurina.* Tigrine F. Large; greyish-brown, with a longitudinal yellow line extending from the nose to the rump; dark brown spots edged with yellow above the limbs, and yellow buttocks.

*La G. tigrée*, Daud. viii. p. 125.

13. *R. grunniens.* Grunting F. Brown or reddish, with oblong yellow spots behind the eyes.

*La G. grognante*, Daud. viii. p. 127.

14. *R. paradoxa.* Paradoxical F. Greenish-ash or reddish above, marbled with reddish brown; thighs marked below with oblique reddish lines. See Plate CCXCVIII. Fig. 20.

*La G Jackie*, Daud. viii. p. 130; Lacep. ii. part iii. art. 11.

*Rana paradoxa*, Linn. a Gmel. p. 1055.

*Paradoxical frog*, Shaw.

*Surinam frog* or *Jackie.*

The natural history of this extraordinary animal is but imperfectly understood. It has long been supposed, that it is first a frog, and afterwards changes into a fish; in which latter state it is eaten by the natives of Surinam, under the names of Jackie and Frog-fish.

Considerable light has been lately thrown on the economy of the Surinam frog by Mr W. M. Ireland and Sir E. Home, in a paper just published in *The Journal of Science* *and the Arts*, 1816, vol. i. p. 55. edited at the Royal Institution by Mr Brande. Mr Ireland has had the good fortune to witness the changes which the animal undergoes from the tadpole to the perfect state; and the following is an abstract of his observations, with those of Sir E. Home, on the internal structure of the tadpole in two of its stages.

When first seen by Mr Ireland, the tadpole was about four inches and a half long by about an inch broad, had a large head and small mouth, very much resembling those of a fish, though the rudiments of two legs were evident just behind the head. In about a fortnight, the length of the animal had increased to eight inches, and its breadth to about two and a half; and the rudiments of the legs were developed into nearly perfect members, with five clawed toes, united by a membrane, evidently the future hind legs of the animal.

On examining its internal structure during this fortnight, the intestinal canal appears very long, and coiled up, and the rudiments of the lungs are seen in the posterior part of the belly.

In about three weeks the fore legs make their appearance, the head and mouth assume their ordinary figure, the former being considerably smaller, and the latter larger than before; and the animal, which till now had lain at the bottom of the vessel in a torpid state, becomes more active and lively, and usually remains suspended in the water, with its mouth above the surface. By this time the intestinal canal is wonderfully altered in extent and appearance, being contracted apparently to less than half its length, and having but very few short convolutions, and nearly the whole of the cavity of the belly is filled with fat.

In about six weeks, the animal is greatly contracted in size, being little more than three inches long by about an inch in breadth, and has become a perfect frog, except some small remains of the tail, which has been gradually sloughing off or absorbed, and the disappearance of which has so greatly contracted the animal's length.

The appearance of the tadpole, in the state usually called the Frog-fish, is shewn in Plate CCXCV. Fig. 17. which is reduced to one-fourth of its natural length, and the animal, nearly in its perfect state, and one-half its natural size, is represented in Plate CCXCVIII. Fig. 20.

15. *R. arunco.* Arunco F. Body warty; feet palmated.

*La G. arunco*, Daud. viii. p. 134.

16. *R. thaul.* Yellow F. Body warty; yellow feet, semipalmated.

*La G. thaul*, Daud. viii. p. 136.

*Rana lutea*, Linn. a Gmel. p. 1050.

### Genus III. Bufo. TOADS.

Body thick, short, and broad, more or less warty on the upper surface; head thick and short; eyes large and protuberant, with a vertical pupil; tongue short and thick; skin dilatable by inflation; belly often granulated; fore feet with four separate toes, the thumb larger in the male; hinder feet comparatively short, and generally palmated with five toes; all the toes pointed, but without claws.

From the construction of their legs and feet, toads do not leap so well as frogs, but they walk better, and swim with facility. In their other habits and modes of life they resemble frogs, except that, when irritated or terrified, they emit from the pores of their warty skin a sort of frothy fluid, which, though not venomous, as was formerly supposed, is sufficiently irritating to affect delicate parts of the skin of an animal that touches it. It is scarcely now necessary to remark, that the stone in the toad's head, which has given rise to Shakespeare's beautiful simile, is only a poetical fiction, those substances which have received that name appearing only to be the fossil teeth of a species of fish.

Toads feed on worms and insects, and in their turn become the prey of the larger birds and snakes; and it is said, that their flesh, so far from being venomous, affords as wholesome nutriment as that of the frog. Some of these animals are also capable of being domesticated. We are informed by Mr Pennant, that an individual of the common toad was known to frequent the steps of a gentleman's house in Devonshire for thirty-six years, where it was accustomed to be fed every evening by the family and their visitors.

The accounts that have been published in various works, respecting living toads found in hollow trees and blocks of stone, however extraordinary, seem so well authenticated, that we can scarcely doubt the reality of such occurrences, though we cannot satisfactorily account for them.

There are about thirty-two species of toad, which are thus distinguished.

*Species* 1. *Bufo vulgaris.* Common Toad. Pale reddish-ash coloured, with red pustules above, reddish-white below.

*Le crapaud cendre a pustules rouses*, Daud. viii. p. 139.

2. *B cinereus.* Cinereous T. Uniformly ash coloured, pustular.

*Le C. cendré*, Daud. viii. p. 141.

3. *B. flaviventris.* Yellow-bellied T. Ash coloured and pustular above, sulphur-yellow below.

*Le C. a ventre jaune*, Daud. viii. p. 143.

4. *B. panamensis.* Panama T. Ash coloured; pustules tipt with violet, yellowish below; feet semipalmated.

*Le C. de panama*, Daud. viii. p. 145.

5. *B. bombinus.* Natter-jack T. Olive-brown above, orange-yellow below, with bluish spots and a fold below the throat.

*Le C. sonnant ou pluviale*, Daud. viii. p. 146.

Among other synonymes under this species, Daudin refers to

*Rana bombina*, Linn. a Gmel. p. 1048; *Rana rubita*, ibid. p. 1047; *Rana salsa*, ibid. p. 1049.

*La sonnante*, Lacepede, ii. part iii. art. 4; *La pluviale*, ibid. art. 3.

*Natterjack*, Pennant, *Brit. Zool.* iii. p. 12.

6. *B. roeselli.* Roesellian T. Greenish above, with elevated dark brown spots; greenish-ash coloured below; feet palmated.

*Le C. de roesel*, Daud. viii. p. 150. plate xcvi.

*Rana bufo*, Linn. a Gmel. p. 1047.

*Toad*, Pennant, *Brit. Zool.* iii. p. 7; Shaw's *Gen. Zool.* iii. plate xl.

*Le Crapaud commun*, Lacepede, ii. part iii. art. 21.

7. *B. calamita.* Calamite T. Olive above, with dark spots, reddish pustules, and a longitudinal yellow line along the middle of the back.

*Le C. calamite*, Daud. viii. p. 153; Lacep. ii. part ii. art. 25.

8. *B. viridis.* Green T. Marked above with contiguous green spots, and irregular whitish-livid lines dotted with red; feet semipalmated.

*Le C. verd*, Daud. viii. p. 156; Lacep. ii. part. iii. art. 22.

9. *B. gibbosus.* Gibbous T. The body ovate, smooth, convex, brownish above, with a longitudinal yellow indented band along the middle of the back; toes separate.

*Le C. bossu*, Daud. viii. p. 158; Lacep. ii. part iii. art. 29.

*Rana gibbosa*, Linn. a Gmel. p. 1047.
*Gibbous toad*, Shaw.

10. *B. fuscus*. Brown T. Marked above with broad brown spots, interspersed with livid ash-coloured lines, and one pale longitudinal line; hind feet palmated.
*L. C. brun*, Daud. viii. p. 161; Lacep. ii. part iii. art. 24.

11. *B. cursor*. Courier T. Smoothish above, spotted with reddish and black, with warty sides, yellowish below, with three black spots upon the breast; toes separate.
*Le C. courier*, Daud. viii. p. 164.

12. *B. gutterrosus*. Swelled throated T. Grey, spotted with brown, warts sharp, and reddish at the tip; throat swoln.
*Le C. goitreux*, Daud. viii. p. 166; Lacep. ii. part iii. art. 28.

13. *B. ventricosus*. Inflated T. Mouth narrow, arms and thighs surrounded with a lax skin, capable of inflation.
*Le C. ventru*. Daud. viii. p. 168.
*Rana ventricosa*, Linn. a Gmel. p. 1049.
*Humid toad*, Shaw.

14. *B. lævis*. Smooth T. Pale yellow, with a smooth, rather flattened body, and a longitudinal row of small pointed tubercles above each side.
*Le C. lisse*. Daud. viii. p. 171.

15. *B. dorsiger*. Surinam T. Dark brown, head flat and triangular; eyes minute, situated at the top of the head; toes of the fore feet separate, and three or four forked at their tips; hind feet palmated; cells on the back in the female.
*Le C. pipa*, Daud. viii. p. 172; Lacep. ii. part iii. art. 30.
*Rana pipa*, Linn. a Gmel. p. 1046.
*Surinam toad*, Shaw, iii. plate xxxi.

16. *B. obstetricans*. Accoucheur T. Dirty green, with small irregular brown spots above; whitish below.
*Le C. accoucheur*, Daud. viii. p. 176.

17. *B. Margaritifer*. Pearly T. A coriaceous auricular lobe above each side of the head; numerous warts upon the body, bearing some resemblance to pearls; hinder feet semipalmated.
*Le C. perlé*, Daud. viii. p. 179.
*Rana margaritifera*, Linn. a Gmel. p. 1050.
*Pearled toad* Shaw.
*La perle* Lacep. ii. part iii. art. 10.

18. *B. Surinamensis*. Dwarf Surinam toad. Bright brown above; belly dotted with grey, with a white line on the hips; all the toes separate.
*Le C. de Surinam*. Daud. viii. p. 184.

19. *B albonotatus*. White spotted T. Brown; slight-warted, with a white line extending from each nostril to each thigh; upper part of the limbs spotted with white.
*Le C. a taches blanches*, Daud. viii. p. 185.

20. *B. ovalis* Oval T. Head short; muzzle long; body ovate, nearly globular; brownish or bluish above, yellowish below; feet palmated.
*Le C. ovale*, Daud. viii. p. 187.

21. *B. lineatus*. Striped T. Warty, brownish red, with a white line drawn from each nostril through the eyelids to the hind feet, another on each arm; white bands upon the limbs, and all the toes separate.
*La C. rayé* Daud. viii. p. 188.

22. *B. musicus*. Musical T. Brown above, with blackish spots; head furrowed above; limbs marked with blackish bands.
*Le C. criard*, Daud. viii. p. 190.
*Rana musica*. Linn. a Gmel. p. 1046.
*Musical toad*, Shaw.

23. *B. Scaber*. Rough T. Yellowish, with black lips; body a little spinous, especially about the legs; head furrowed above; hind feet slightly palmated.
*Le. C. rude*, Daud. viii. p. 194.
*Le pustuleux*, Lacepede, ii. part iii. art. 27.

24. *B. bengalensis*. Bengal T. Body thickly covered with warts; yellowish grey; head slightly furrowed above; black sharpish pointed warts below the feet; hind feet semipalmated.
*Le C. du Bengale*, Daud. viii. p. 197.

25. *B. spinosus*. Spinous T. Dark brown above, with broad spots of a paler hue; pale grey below, with tubercles tipt with a black spine.
*Le C. epineux*, Daud. viii. p. 199.

26. *B. horridus*. Horrid T. Dark green above; warty, with numerous small black spines on each tubercle, marbled below with green and paler shades; all the toes separate.
*Le C. hérissé*, Daud. viii. p. 201.
*Australian frog*, Shaw.

27. *B. spinipes*. Spine-footed T. Brown above, bluish below; sides marked with ochry colour; fore feet spinous above.
*Le C. spinépede*. Daud. viii. p. 203.

28. *B. humeralis*. Shoulder-knot T. Very large; ash-grey, irregularly spotted with brownish; parotid glands large and gibbous.
*Le C. epaule armée*, Daud. viii. p. 205.
*Rana marina*, Linn. a Gmel. p. 1049.
*La grenouille epaule armée*, Lacep. ii. part iii. art. 8.
*Marine toad*, Shaw.

29. *B. semilunatus*. Semilunated T. Blackish, with a white spot behind each ear; head slightly furrowed above; hinder feet semipalmated.
*Le C. demi-lune*, Daud. viii. p. 208.

30. *B. agua*. Brazilian T. Very large; beautifully marbled with yellow, brown, and grey, and rough with tubercles; large parotid glands; hinder feet very slightly palmated.
*Le C. ague*, Daud. viii. p. 209.—Lacep. ii. part iii. art. 32.
*Rana braziliensis*, Linn. a Gmel. p. 1049.

31. *B cyanophlytis*. Blue-warted T. Bluish brown above, with blue pustules on each side, extending from the eyes to the lower part of the breast and sides, and thence to the rump.
*Le C. a pustules bleues*. Daud. viii. p. 212.

32. *B. cornutus*. Horned T. Head large, with a long conical protuberance, or horn, upon each upper eye-lid.
*Le C. cornu*, Daud. viii. p. 214.—Lacepede, ii. part iii. art. 31.
*Rana cornuta*, Linn. a Gmel. p. 1050.
*Horned frog*, Shaw.

### FAMILY II. *Tailed Batracians.*

### GENUS IV. SALAMANDRA. SALAMANDERS.

Body elongated, cylindrical, naked, sometimes warty, and terminated by a tail that is either cylindrical or flattened, so as to form a fin, and persistent. No external ears; tongue short, thick, and entirely fixed within the lower jaw. Fore feet having either three or four toes; hinder furnished with five toes, all blunt, and without claws.

Till within these few years, the salamanders had been ranked among the lizards, to which they are allied only from their having a tail, and from the similar position and structure of their legs. In their internal organization and their general habits, they are entirely distinct from all the Saurian order, and more nearly resemble the frogs and toads. They have no true ribs; they respire in the same manner as the Batracians already described, and in most of them the fecundation of the ova takes place in a similar manner. In a few of them, indeed, the young are extruded from the ova while still within the oviduct of the female; and the species in which this takes place are called *ovoviviparous*. In their metamorphoses, the young salamanders pass through the early stages of existence with much the same appearances as we have described in the tadpole of the frog, except that the number of stages is rather less. The tadpole of the salamander bursts the ovum within ten days after it is dropped from the mother, and takes about four months to arrive at its perfect state, during which time it subsists entirely on vegetables; while in their perfect state, they feed on snails, worms, and insects. The number of young produced by one female salamander sometimes amounts to thirty or forty.

These animals are found in most warm climates; and at least six of them are natives of the south of Europe. They inhabit the banks of unfrequented streams, moist shady woods, and high grounds; but are seldom seen except during wet weather. They appear to live equally well in the water and on land, and they swim with great facility. During winter they lie concealed about the roots of old trees, in the cavities of old walls, or in subterranean recesses, where they are sometimes found twisted together. In their general habits, they are very sluggish, and their pace is slow.

It was believed by the ancients, and is still a popular superstition among the vulgar in most countries, that salamanders are not only capable of existing with impunity in fire, but have the power of putting a stop to a considerable conflagration when thrown among the flames. This absurd idea has perhaps arisen from the fact which has been observed by Maupertuis, that when one of these animals is placed upon a fire, its whole body soon becomes covered with drops of a milky fluid, which oozes through the pores of the skin, and quickly dries upon its surface.

There are about fourteen species, which are thus distinguished.

*Species* 1. *Salamandra terrestris.* Common salamander. Blackish, variegated with irregular blackish spots; tail cylindrical, and a little obtuse.

*La Salamandrie terrestre*, Daud. viii. p. 221. pl. xcvii. fig. 1.—Lacepede, ii. part ii. art. 54. pl. viii. fig. 1.

*Lacerta salamandra*, Linn. a Gmel. p. 1066.

*Salamander*, Shaw, iii. pl. lxxxii.

2. *S. atra.* Black S. Uniformly black without spots; tail cylindrical and a little obtuse.

*La S. noire*, Daud. viii. p. 225.

3. *S. rubra.* Red S. Red interspersed with numerous black points, with a blackish streak upon the belly: hinder feet semipalmated.

*La S. rouge*, Daud. viii. p. 227.

4. *S. venenosa.* Venemous S. Ground black, with round yellow spots, arranged in a double row along the back.

*La S. venimeuse*, Daud. p. 229.

*Lacerta punctata*, Linn. a Gmel. p. 1076.

*La ponctuée*, Lacepede, ii. part ii. art. 56.

5. *S. alleganiensis.* Alleghany S. Large, brown, paler below, with a shortish compressed tail, slightly crested.

*La S. des monts alleganis*, Daud. viii. p. 231.

6. *S. cristata.* Crested S. Blackish above, marked below with large rounded orange-coloured dots; sides granulated with white, and dotted with black; tail compressed; back of the male furnished with a fimbriated crest.

*La S. crêtée*, Daud. viii. p. 233.

7. *S. rubriventris.* Orange bellied S. Black above, with brownish spots; orange below without spots, except a few black dots under the neck.

*La S. a ventre orangé* Daud. viii. p. 239. pl. xcviii. fig. 1.

8. *S. marmorata.* Marbled S. Olive green above, marbled with brown; brownish below, with white granular dots; tail compressed.

*La S. marbrée*, Daud. viii. p. 241.

9. *S. abdominalis.* Abdominal S. Olive green above, dotted with yellow below, with a longitudinal yellowish line on each side of the back; all the toes separate.

*La S. abdominale*, Daud. viii. p. 250

10. *S. palmipes.* Webfooted S. Head and arms yellow, slightly dotted with black; back olive brown; belly yellowish; hind feet palmated.

*La S. palmipéde*, Daud. viii. p. 253. pl. xcviii. fig. 2.

11. *S. elegans.* Elegant S. Head and feet yellow, slightly dotted with black; back olive; belly yellowish; all the toes separate, but those of the hind feet lobated.

*La S. elegante*, Daud. viii. p. 255.

12. *S. punctata.* Dotted S. Olive ash above, yellow below, every where interspersed with black bots; tail very much compressed; all the toes separate.

*La S. ponctuée*, Daud. viii. p. 257.

13. *S. cincta.* Girded S. Yellowish olive above, dotted yellow below with a white streak; edged below with black dots; all the toes separate.

*La. S. ceinturée*, Daud. viii. p. 259.

14. *S. Trydactyla.* Three-toed S. Fore feet three-toed; hind feet four-toed.

*La S. tridactyle*, Daud. viii. p. 261.—Lacep.

*Le Lizard tridactyle*, Lacep. ii. part. ii. art. 59.

### Genus V. Proteus. PROTEUS.

Body elongated, cylindrical, terminated by a compressed tail forming a fin; tongue short, thick, adhering within the lower jaw; fore feet furnished with three toes, and the hinder with two; all without claws; branchiæ persistent.

*Species. Proteus Anguinus.* Serpentine Proteus. Fore feet three-toed; hind feet two-toed.

*Le proté anguillard*, Daud. viii. p. 266. pl. xcix. fig. 1.

*Proteus anguinus*, Laurenti, *Synops. Reptil.* p. 37. pl. ii. fig. 3.—Scopoli, *Annales Hist. Nat.* vol. v. p. 70.—Linn. a Gmel. p. 1056, note.—Herman, *Tab. Affinitat. Animal.*—Schneider, *Hist. Amphib. fascic.* i. p. 45.—Schreiber, *Phil. Trans.* 1801.

The curious animal for which the present genus has been constituted, was first observed at the bottom of a lake in Carniola in Germany, and described in 1768, by Laurenti, in the work referred to above. It was afterwards described by Scopoli, and was briefly noticed by Linnæus in his *Systema Naturæ*, who, however, considered it as the tadpole of a salamander; but the most complete account of the animal has been given by Schreiber, a German naturalist, in a memoir of his, published in the Transactions of the Royal Society of London for 1801. From this account it is now generally allowed, that the Proteus is to be considered as a perfect animal, differing from all the other reptiles with which we are acquainted.

Its general length is about thirteen inches by about one inch of medium breadth, and the head is nearly two inches long. It has no external nostrils; and its eyes, which are black, and situated towards the base of the muzzle, are so small as with difficulty to be distinguished. The colour of the living animal is a flesh red, and the gills are scarlet;

but when immersed in spirits after death, it becomes white. It appears to walk with difficulty, but swims with great ease. One that was kept by Baron Zois lived for about ten days, and during that time refused all nourishment, and appeared in a torpid state.

The Proteus undergoes three degrees of metamorphosis before arriving at its perfect state. In the two former, it is blind and without feet.

It is said on certain occasions to utter a sound resembling that made by forcing down the piston of a syringe.

Two reptiles have lately been noticed by the French naturalists, bearing a near relation to the Proteus above described. One has been described by Cuvier, under the name of *Axolote Mexicaine*, and has four toes on each fore foot, and five on each hinder. This we might call *Proteus mexicanus*. The other is described and figured by Lacepede, in the tenth volume of the *Annales de Museum*, p. 230. pl. xvii. by the name of *Protée tetradactyle*, (*Proteus tetradactylus*,) with four short pointed toes on each of the fore feet. It differs from the Proteus anguinus in having a thicker and shorter body, a much broader tail, and the legs larger and shorter.

### Genus VI. Siren. SIREN.

Body elongated, cylindrical, and terminated by a compressed tail, forming a fin; tongue short, thick, and adherent; fore feet digitated; no hind feet; branchiæ persistent.

*Species. Siren lacertina.* Lacertine Siren. Feet four-toed.

*La Siren lacertine*, Daud. viii. p. 272, pl. xcix. fig. 2.

*Siren lacertina*, Linn. *Amœnit. Academ.* vii. p. 311.

*Muræna siren*, Linn. a Gmel. p. 1136.

*Siren lacertina*, Shaw's *Naturalist's Miscellany*, N°. 20, pl. lxi.—Schneider, *Hist. Amphib.* fascic. i. pl. 48.

The extraordinary reptile which constitutes this last genus of Batracians, was first observed in 1765, by Dr Alexander Garden, in a fresh water lake near Charlestown in Carolina, and was described by Linnæus in the Memoirs of the Academy of Upsal for that year. He considered it either as the tadpole of a species of lizard or salamander, or as a new genus of his order Nantes, to which he gave the name of Siren. Soon after, Linnæus placed the Siren in the order Amphibia, which he denominated Meantes, from which Gmelin, in his edition of the *Systema Naturæ*, injudiciously removed it to the class of Fishes, and considered it as a species of *muræna*.

The Siren very much resembles an eel in the general form of the body and tail. Its mouth is small, and furnished with small sharp teeth, set partly in the palate, and partly in the lower jaw. Its eyes are very small, but more evident than those of the Proteus. Its skin is of a blackish colour, slightly grained and porous, with a longitudinal white line, extending on each side from the feet to the tail, and a shorter one along the middle of the back. The whole length of the animal sometimes exceeds three feet; and the feet, which are small, and composed of a *humerus*, a fore arm, and four small pointed toes, furnished with claws, are about an inch long.

Its tongue is bony, and formed like that of fishes; the gills are composed of three fimbriated plates on each side, are very apparent, and are above half an inch long. It has a real larynx, and its lungs resemble those of salamanders. In its metamorphosis from the ovum to the perfect state, it seems to follow the same degrees with the *Proteus*, except that its eyes are sooner open.

This animal appears to reside entirely in the water, where it must swim with great facility. It was supposed by Linnæus, from the form of its feet, that it can also move with tolerable ease upon the land; but we believe it has never yet been seen in that situation.

## EXPLANATION OF PLATES.

### PLATE CCXCV.

Fig. 1. Skeleton of a species of Tupinambis.

Fig. 2. The head of the same animal. *a*, the intermaxillary bone; *b*, *b*, the two superior, or coronal maxillary bones; *c*, the nasal bone; *d*, one of the zygomatic arches; *e*, a supernumerary bone; *f*, *f*, the two sides of the frontal bone; *g*, the parietal; *h*, *h*, two bony arches forming the interior border of the temporal fossa; *i*, a small portion of the left basilar jaw; *k*, the bone with which this is articulated; *l*, *l*, the occipital bone; *m*, its condyle.

Fig. 3. The jaws of the Nilotic crocodile extended, shewing the mode of their articulation.

Fig. 4. Stomach of the common land tortoise.

Fig. 5. Stomach of the Gavial crocodile, with a portion of the intestinal canal commencing at *a*, the pylorus.

Fig. 6. Stomach of the Nilotic crocodile partly laid open; *a*, a pouch into which the aliments pass before proceeding out at *b*, the pylorus.

Fig. 7. Stomach and intestines of the Chameleon; *a*, the *pylorus;* from *a* to *b*, the small intestine; *b*, the commencement of the large intestine.

Fig. 8. Part of the intestines of the land tortoise; *a b*, a part of the small intestine; *b*, the commencement of the large intestine.

Fig. 9. The *rectum* of the Nilotic crocodile insensibly commencing from the small intestine; *a a*, a valve between the two.

Fig. 10. *Rectum* of the Gavial; *a*, the termination of the small intestine; *b*, the rectum; *c*, a projection from the small intestine into the large for acting as a valve.

Fig. 11. Stomach and intestines of the Siren; *a* the *pylorus;* *b*, the termination of the hepatic duct.

Fig. 12. The heart of the crocodile seen on its lower surface; *a a*, the right auricle; *c*, the common trunk of the right carotid and right brachial arteries; *d*, the common trunk of the same arteries on the left side; *e e*, the continuation of the right posterior *aorta;* *f f*, the left posterior aorta: *g h*, the left and right pulmonary arteries; *i k*, the pulmonary veins; *o*, the opening by which the right auricle communicates with the inferior compartment of the ventricle; *p*, an orifice by which this compartment communicates with the pulmonary cavity of the ventricle; *q r*, two valves at the commencement of the left aorta; *s*, *t*, the trunks of the two arteries *c* and *d* laid open; *v*, the trachea; *x x*, its sub-divisions into bronchi; *y y*, situation of the lungs.

Fig. 13. The heart of the crocodile viewed on its inferior surface, but a little more to the left side.

Here the letters *a*, *c*, *d*, *e*, *f*, *g*, *h*, refer to the same parts as in the preceding figure. *b*, the left or pulmonary auricle; *m*, a row of tubercles behind; *x*, *y*, the valves guarding the entrance of the left pulmonary artery; *z*, the communication between the inferior and pulmonary compartments of the ventricle.

Fig. 14. The crocodile's heart seen on its upper surface; where the letters *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, *k*, refer to the same parts as in the former figures. *l*, the upper compartment of the ventricle laid open.

Fig. 15. The general appearance of the ova of frogs, as extruded from the oviduct.

Fig. 16. The tadpole of the frog, when only a few days old.

Fig. 17. The tadpole of the Surinam frog in that stage called *frog fish*.

Fig. 18. Is the under surface of one of the toes of the *Gecko Egyptiacus*, of the natural size. See p. 29.

Fig. 19. Is a toe dissected to shew the appearance of the pockets on its under surface, their serrated cuticular edges, the depth of the pockets, and the small muscles by which they are drawn open, the parts being highly magnified: *a a* are the two muscles which lie on the sides of the bones of the toe, with their tendons inserted into the last bone, close to the root of the claw. The muscles belonging to the pocket go off from these tendons.

PLATE CCXCVI.

Fig. 1. *Chelonia mydas.* Green turtle.
Fig. 2. *Testudo Græca.* Common land tortoise.
Fig. 3. *Crocodilus Niloticus.* Crocodile of the Nile.
Fig. 4. *Dracæna.* Dragon lizard.
Fig. 5. *Tupinambis ornatus.* Ornamented tupinambis.
Fig. 6. *Basiliscus mitratus.* Mitred basilisk.
Fig. 7. *Iguana delicatissima.* Common guana.
Fig. 8. *Draco volans.* Flying dragon.

PLATE CCXCVII.

HERTFORD TOWN, in the hundred of Hertford, in Hertfordshire, is pleasantly situated 21 miles north from London, on the river Lea, which is navigable for barges to the town. The streets are chiefly neat and clean, and the houses well built. It contains two parish churches; a handsome sessions house, in which the assizes for the county are held; a market house and town hall, in which are kept the quarter sessions and county courts; and a county gaol and penitentiary house, built on Mr Howard's plan. The most important public seminaries for education consist of the East India College, for the education of youth destined to fill the various offices in the civil departments in India; and a large school belonging to Christ's Hospital in London, where about 500 of the younger children are kept prior to their being sent to the metropolis. Hertford returns two members to parliament. The right of election is vested in the inhabitants who do not receive alms; and in such freemen only as, at the time of their being made free, were inhabitants of the borough. Their number is about 700. The only article of consequence manufactured here is malt, by which, and the large quantities of corn and wool sent down the river to London, the inhabitants are principally supported.

In 673, a synod was held at Hertford, and King Alfred here built a castle, by means of which the Danes, who had come up the Lea from the Thames, were destroyed. On the site of the ancient castle the present one, now the East India College, was erected in the time of Charles I. The manor of Hertford belonged to the Crown from 1345 till the sixth year of Charles I., when it was granted to William Earl of Salisbury, whose descendant, the present marquis, is now owner of it. In the 25th year of the reign of Elizabeth, and afterwards, in the 34th and 35th of the same reign, the Michaelmas term was adjourned from London to this town, on account of the plague then raging in the metropolis.

At Haileybury, in the parish of Amwell, in the vicinity of the town of Hertford, and about 19 miles from London, is situated the East India College. This site was chosen by the directors of the East India Company, when they formed the determination of abandoning the grand and extensive plan of a college at Calcutta, sketched out and partly begun by the Marquis of Wellesley, during his administration of India. The object of both institutions is to give a suitable education to those persons who are meant to occupy civil employments under the company in India.

The college near Hertford was instituted in April, 1805, and the foundation stone of the building was laid on the 12th of May, 1806. The beauty of the building, the fineness of the situation, the salubrity of the air, and the object of the institution, render it an object of considerable interest. The college is capable of accommodating above 100 students, and rather more than thirty, on an average, are annually sent from it to India. According to the plan of the institution, young men are received when they have completed their 15th year, and they continue at the college till they are 18, or till the court of directors shall deem it proper to send them to their respective destinations. A nomination to the college, on the part of the court, is equivalent to an immediate appointment. The students are instructed by courses of lectures, nearly on the plan pursued at the universities of Oxford and Cambridge. The college council, under whose direction and authority the institution is more immediately placed, consists of a principal and several professors. Besides the general superintendance of the college, it is the duty and office of the principal more especially to watch over the moral and religious conduct of the students, to instruct them in the principles of ethics and natural theology, and in the evidences, doctrines, and duties of revealed religion. Besides, he, as well as such of the professors as are in holy orders, preach in the college chapel. The principal is assisted in the superintendance of the college by the dean, who is annually chosen from among the clerical members of the college council.

The lectures of the professors are arranged under four heads, viz. oriental literature: 1st, Practical instruction in the rudiments of the oriental languages, especially the Arabic, Persian, Hindostanee, Sanscrit, and Bengalee. 2d, A course of lectures to illustrate the history, customs, and manners of the people of India. In these two departments there is a professor for the languages, a professor of Hindoo literature, and of the history of Asia, two assistants who are natives of the East, and a Persian writing master. There is also a visitor and councillor in the oriental department. Under the second head are included mathematics and natural philosophy, for which there are two professors. The third head comprises classical and general literature, for which there are two professors. The fourth head comprises a course of lectures on general polity, and on the laws of England, and the principles of the British constitution; a course of lectures on general history, and on the history and statistics of the nations of modern Europe; and a course of lectures on political economy. For these subjects there are two professors. There are also attached to the college, masters for French, drawing, and fencing.

The college year is divided into two terms of twenty weeks each, with a summer vacation of eight weeks, and a winter vacation of four weeks. The principal examination takes place previous to the winter vacation, and continues three weeks. It is terminated by a visitation of the court of directors, when the result of the examination is presented by the principal, in separate lists for each department, of the respective merits of each student. These lists are inserted in the public records of the company. Other lists are also given in, exhibiting a relative view of the conduct and proficiency of each student. Prizes of books, medals, &c. and certificates of superior merit, are publicly given by the chairman. Every student going to India carries with him a certificate under the college seal, attesting what his attainments have been during his academical course.

In 1801, Hertford contained 515 houses, and 3360 inhabitants. In 1811, the population abstract gave as follows:

| | |
|---|---|
| Houses inhabited | 592 |
| Families inhabiting them | 735 |
| Males | 2038 |
| Females | 1862 |
| Total | 3900 |

See Arthur Young's *Agriculture of Hertfordshire; Beauties of England and Wales*, vol. v.; Lyson's *Environs of London*. (W. S.)

HERTFORDSHIRE is an inland county of England, bounded by Bedfordshire and Cambridgeshire towards the north and west, Buckinghamshire towards the west, Essex towards the east, and Middlesex towards the south. Its limits are principally artificial, except on the south east, where it is separated from Essex by the rivers Lea and Stort. From Bailey to Royston, the Ikenild Street, one of the four Roman highways running through the island, divides the counties of Cambridge and Hertford. It is intermixed with Buckinghamshire in a singular manner, so that its shape on the western side is rendered extremely irregular by projections and indentures. It is situated between the parallels of 51° 37′ and 52° 5′, north latitude. Its greatest length may be reckoned at 25 miles, and its breadth from north to south at 35 miles. According to Halley, it contains 451,000 acres; but according to the poor's rate returns, only 385,000. It is among the smallest counties in England. The general aspect of this county is pleasant. The northern part is the most hilly, forming a scattered part of the chalky ridge which extends across the kingdom in this direction. A range of high ground stretches out from the neighbourhood of Kings Langley, towards Berkhampstead and Tring. Another elevated ridge commences at St Albans, and proceeds in a northern direction towards Market Street. A number of streams take their rise from this side of the county.

Hertfordshire contains 1 county town, Hertford; 8 hundreds; 19 market towns; 120 parishes; returns 6 members to parliament, viz. 2 for the shire, 2 for Hertford, and 2 for St Albans; and is in the province of Canterbury, and diocese of London. There are no places of any consequence in it besides Hertford, St Albans, Royston, and Ware.

Most of the county is enclosed; and in consequence of its being very ill situated for coals, the old hedges are every where filled with oak, ash, sallow, &c. Independent of the wood thus distributed in hedge-rows, very fine timber, in considerable quantity, is spread over every part of the county. The prevailing soils are loam and clay, in general not of a very fertile quality. The vales, however, through which the rivers and brooks flow, are composed of a rich sandy loam. The most productive soil of this nature is on the west side of the river Lea. The principal clay district is on the north-east on Essex side. In the parishes of North Miny, &c. the general description of soil is extremely barren. The chalky soil prevails on the north side of the county. The basis, indeed, of the whole of Hertfordshire is chalk, intermixed with a great quantity of flints. The landed property is greatly divided, in consequence of the vicinity of the metropolis.

The principal rivers are, the Lea, the Rib, the Quin, and the Colne. The Lea enters this county near Bower-heath, and traverses it in a direction nearly from north-west to south-east, to its confluence with the Stort, after which it runs nearly south, washing the towns of Hertford and Ware, from the last of which it is navigable to the Thames. It collects, in its course, all the streams in the northern and eastern part of the county. The Rib, which rises in this county, joins the Lea between Hertford and Ware: the Quin also rises in this county, and falls into the Rib. The Colne rises near Kits-end, in Middlesex; and after uniting various streams on the south-western side, conveys them out of the county near Rickmansworth. In one part of its course, near Colney Park, it has a short underground passage, though not particularly observable, except in dry weather. The nine sister-springs of the Cam, and the springs which constitute the source of the New River, are in Hertfordshire. The grand junction canal enters this county above Berkhampstead, and leaves it following the course of the Colne. The Watford canal commences near the town of Watford, where it unites with the grand junction, and goes to St Albans.

Farms are in general small. Perhaps the size most common is from 150 to 400 acres. The principal part of the land is under tillage, and the produce in wheat, barley, and oats, is very considerable. Wheat and barley in particular are grown here, of as good a quality as in any other part of the kingdom. In the neighbourhood of Wheathampstead, great quantities of wheat have been grown for a very considerable length of time, whence this place takes its distinctive appellation. Indeed, in the opinion of many, Hertfordshire was distinguished for the excellence of its tillage husbandry, even before Norfolk. Turnips and clover are supposed to have been introduced in the time of Cromwell, who, it is said, gave 100*l.* a year on that account, to a farmer of the name of Howe. Even the judicious culture and application of tares were practised in this county upwards of 80 years ago—at a period when they were scarcely known in any other part of England. It does not seem, however, that the arable husbandry of Hertfordshire has improved much latterly; and the kind of plough still in general use will, with many, be deemed a proof of this remark. This plough, known by the name of the great Hertfordshire wheel plough, though of great merit and utility in breaking up strong flinty fallows in a dry season, ought certainly to be dispensed with in all the other operations of husbandry; and, even for that purpose, it might be constructed in such a manner as to do its work with more ease to the horses. It is excessively heavy, and so ill formed, that it will not move in its work one yard without the ploughman. The plough-shares alone weigh from 50 to 70 lbs.

The grass-lands of Hertfordshire, compared with those under tillage, are very trifling: in fact it may be said, that there is no grass district in it, except a very narrow margin in the south line, in the vicinity of Barnet, which, being near London, is made artificially productive, by means of manure brought by the hay carts. There are, however, some tolerably good meadows, especially those on the Stort, extending from Hackerell to Hertford, and those in the vicinity of the Lea, and about Rickmansworth. The many streams that flow through the county are extremely favourable to irrigation, though that system is not carried to any great extent. In the south-west corner of the county are many orchards. Apples and cherries are their principal produce.

As the land in this county is chiefly arable, and the artificial grasses are cultivated almost entirely for hay for the London market, live stock is an object of very inferior consideration. The Suffolk breed of cattle is regarded as the best. The sheep are mostly ewes of the Southdown and Wiltshire breeds. The horses are of various kinds, but the Suffolk punch appears to be preferred.

The principal roads in Hertfordshire, in consequence of its vicinity to the metropolis, are very good. Six great leading turnpikes pass through this small district. Many of the cross roads are nearly as good as the turnpikes.

The great business of the county is the traffic of corn, and the malting trade. The latter is carried on to a very great extent in the towns of Hitchin, Baldock, Royston, and Ware. Ware alone sends a greater supply of malt to London than any other place; and it always obtains the highest price, not only on account of the excellence of the barley from which it is made, but also for the excellence of the mode in which it is manufactured. The Hertfordshire malt, however, is not all made from barley grown in the county; large quantities being purchased in all the surrounding districts, which after being malted in the towns above mentioned. is sent to London chiefly by the navigation of the Lea. There are very few manufactures in Hertfordshire of any consequence; at St Albans there is a small cotton manufactory, and two silk-mills. The machinery of the latter is particularly well contrived. At Berkhampstead fringe lace is made; and also a considerable quantity of wooden shovels, bowls, spoons, &c. In this, and some other parts of the county, plaiting straw is a resource for poor women and children. At Watford there are some silk mills, one of which is worked by the waters of the Colne; the rest by horses. In 1803 the poor rates amounted to 71,291*l.*: in 1815, they had increased to 98 380*l.*

There are several antiquities of great interest in this county. The British City of Verulam, on the site of which St Albans stands, is of greater antiquity than even London itself; and, under the dominion of the Romans, acquired the dignity and privileges of a municipium. In the vicinity of this place Cæsar defeated Cassivellaunus; Boadicea conquered and massacred 70,000 Romans and Britons; and two bloody battles were fought between the rival houses of York and Lancaster, in 1455 and 1461. The field of Barnet, between St Albans and London, was also the scene of a bloody battle in the destructive wars of the two houses, which proved decisive in favour of Edward IV., his great foe, the Earl of Warwick, surnamed the king-maker, being there slain in 1471. During the Saxon Heptarchy, this county was partly in the kingdom of the East Saxons, and partly in Mercia. The king of the latter resided in a castle at Berkhampstead. At this place a parliament was held in 697, and the laws of Ina were published. William the Conqueror here swore to preserve the laws made by his predecessors. King Henry II. kept his court here, and granted it all the liberties and privileges which it had engaged under Edward the Confessor; and so lately as the reign of James I the royal nursery was established here. Upon a hill in Harborough field, near Ashwell, are evident marks of a Roman fortification, (now called Ardbury Banks,) a large square work enclosed with a trench or rampart. Here the Romans had a standing camp, so advantageously situated, that they could discover the approach even of a small body of men at a great distance. Several Roman coins and earthen vessels have been dug up here at different times.

In 1801 there were 18.172 houses in this county, and 97,577 inhabitants. In 1811, it appears, from the population abstract, that there were—

| | |
|---|---|
| Houses inhabited | 20,345 |
| Families inhabiting them | 22,744 |
| Houses building | 131 |
| ——— uninhabited | 436 |
| Families employed in agriculture | 11,998 |
| ——————— trade | 7,192 |
| ——————— other lines | 3,554 |
| Males | 55,023 |
| Females | 56,631 |
| Total inhabitants | 111,654 |

The following is the statistical state of the county in 1811:

| | |
|---|---|
| Area in square statute miles | 528 |
| English statute acres | 337,920 |
| Rental of land | *l.*342.350 |
| Amount of tithe | 45 292 |
| Annual value of a square mile | 735 |
| Number of persons in a square mile | 211 |
| Agricultural population in centesimal parts | 52 |
| Net product per family | 32 |

(W. S.)

HESIOD, one of the earliest Greek poets. Little is known of his life, and the few facts that have reached us have occasioned much controversy among the learned. It appears that his father Dius had originally resided at Cuma, a town of Æolia in Asia Minor, whence he afterwards removed to Ascra, now Zagara, situated in a valley of Mount Helicon. (See Helicon and Clarke's *Travels*, part ii. sect. iii. p. 112.) It is uncertain whether Hesiod accompanied his father from Cuma, or was born at Ascra. The latter is perhaps the more probable conclusion. In one of his poems he mentions a short voyage to the isle of Eubœa as the only occasion on which he had ever been on shipboard; but if he had come from Cuma, he must have crossed by sea into Greece. It is true, in the passage alluded to, he speaks of his nautical experience, but the affirmation is unlimited; and it may be supposed, had there been any exception, that exception would either have been noticed, or the expression modified. There is another presumption in favour of Ascra, given by Plutarch on the authority of Ephorus, the historian of Cuma, who relates that Dius had been compelled to emigrate to Ascra, on account of debt, and there married Pycimede the mother of Hesiod. What was Hesiod's occupation is uncertain. La Harpe, in his *Cours de Literature*, supposes him to have been a priest of the Temple of the Muses. Others have maintained, that, according to the Proem to his Theogony, he tended sheep in the vallies of Helicon; a mode of life, it has been thought, better suited and more congenial to the bard of husbandry; though it is evident, as the writer of the Theogony, the same reason applies with equal force in favour of his sacerdotal profession. From the picture of the Muses presenting him with a laurel branch, Mr Elton infers, with Pausanias, that he was not a minstrel or harper, but a rhapsodist, and sang or recited to the branch instead of the lyre." He is reported to have carried off the prize from Homer at a poetical contest. That he won a contested prize in Eubœa, as noticed in his poem of the *Works and Days*, cannot reasonably be doubted; but that he vanquished Homer has been justly regarded as a fiction of later times. Hesiod is noted for longevity, but it is uncertain whether he was permitted to die a natural death. There is a tradition that he was murdered at Ænoe, on a pilgrimage to the Delphic oracle, by the son of his host Ganyetor. Ganyetor having entertained Hesiod, and a Milesian, his fellow-traveller, and his daughter having been violated in the night, suspicion fell upon the aged bard, who, without further ceremony, was put to death by the brothers, and thrown into the sea. The body being cast on shore, or, as fiction will have it, conveyed to land by a dolphin, was recognised by his dog, and the murderers, upon confession, were drowned in the waves.

The era of Hesiod is still more doubtful than his birthplace. Some authors, as Quintilian, Heinsius, and Justus Lipsius, give him a greater antiquity than Homer; Cicero, Pliny, and Paterculus, place him a century later; while a third party, among whom are Plutarch and Varro, supported by the venerable authority of Herodotus, concur in making him a contemporary. The attempts to decide the question of priority, from philological criticism and astronomical calculations, are equally vague and ineffectual. The inference in favour of Homer, which has been drawn from his use of the word θεμιστας for law, when Hesiod employs νομους, alleged to be of more recent origin, is of no force, as Mr Elton justly remarks, "unless we suppose that Homer's poems contained every word in the language." The ingenious argument of Dr Samuel Clarke, on the same side, with regard to the quantity of καλος, of which in Homer the first syllable is long, while Hesiod varies it at pleasure, and of οπωρινος, the penult of which in Homer is long, and short in Hesiod, is scarcely more successful. The difference of locality, of dialect, and, more particularly, the very considerable alterations which the original poems have manifestly undergone since their collection and arrangement, do not admit of any conclusive argument being founded on such minute diversities. Paterculus places Hesiod 800 years before Christ, and Homer 920; and Herodotus, making them contemporaries, fixes their common era at 884 years before Christ. According to the Parian marbles, Hesiod flourished before Christ 944 years, and Homer 907.

Few of the poems* ascribed to Hesiod are now extant, and there is much difference of opinion respecting the small number that have reached us; these are the Theogony, the Works and Days, and the Shield of Hercules. These remains have manifestly suffered greatly from corruption and mutilation. The many spurious additions and alterations with which modern interpolators have loaded and disfigured them have so changed their original simple character, as to raise serious doubts of their antiquity.

Joseph Scaliger denies that the Shield of Hercules is the production of Hesiod, while Tanaquil Faber as confidently affirms it to be genuine. This contrariety of decision, in persons so competent to decide, can be accounted for only by the unauthentic and adulterated state of the poem. With regard to his rank as a poet, Quintilian has given him the slender praise of mediocrity. "If the Battle of the Titans," says Mr Elton, "be Hesiod's genuine composition, and if the Shield, as there is reason to believe, contain authentic extracts from his heroical genealogies, we shall decide that Hesiod, as compared with Homer, is less rapid, less fervent in action, less teeming with allusions and comparisons; but grand, energetic, occasionally vehement and daring; but more commonly proceeding with a slow and stately pace. In mental or moral sublime, I consider Hesiod as superior to Homer."

We subjoin a list of the lost poems of Hesiod.—The Catalogue of Women or Heroines, in five parts, of which the fifth appears to have been entitled "The Herogony." The Melampodia, a poem on divination. The great Astronomy, or Stellar Book. Descent of Theseus into Hades. Admonitions of Chiron to Achilles. Soothsaying and Explications of Signs. Divine Speeches. Great Actions. Of the Dactyli of Cretan Ida; discoverers of iron. Epithalamium of Peleus and Thetis. Ægemius. Elegy on Batrachus, a beloved youth. Circuit of the Earth. The Marriage of Ceyx. On Herbs.

See an ingenious dissertation on the *Life of Hesiod*, prefixed to a new translation of his *Remains*, by Charles Abraham Elton. Lond. 1815. (*v*)

HERSCHEL, is the name given by some astronomers to the Georgium Sidus. See Astronomy and Uranus.

HESSE, a principality of Germany, is bounded on the south by the bishopric of Fulda, the principalities and the counties of Irenburg, Nidda, and Solms; on the east, by Brunswick Eichsfeld and Thuringia; on the west, by Solms, Nassau, Westphalia, and Waldeck; and on the north, by Waldeck, Padenborn, and Brunswick. Its figure is irregularly oval, and it extends about 60 miles from north to south, and from 50 to 70 from west to east. It occupies 2760 square miles, and contains 750,000 inhabitants.

The greater part of this principality was annexed by Bonaparte to the new kingdom of Westphalia; and the grand duchy of Hesse, which was one of the states of the Confederation of the Rhine, was formed out of new territories. Before the peace of Presburg it contained 154 square German miles, and had a population of 319,000; after the peace of Presburg, its extent was 202 square miles, its population 478,800, its military contingent 4000, and its revenue in rixdollars 1,660,000. An account of this principality will be found in our article on the circle of the Rhine, of which it forms a part. See Cassel and Darmstadt.

HEVELIUS, or Hoevelke, John, a celebrated Polish astronomer, was born at Dantzic on the 28th January 1611, and was the son of a brewer of that city. After studying mathematics under Peter Cruger, he travelled through Holland, Germany, England, and France, between the years 1630 and 1634; and upon his return to his native place, he was principally employed in the affairs of the republic of Dantzic, of which he was made consul in 1651. About the year 1660, by the advice of his former master, he devoted himself wholly to the study of astronomy. In the year 1641, he built an observatory at his own expense, and furnished it with excellent telescopes and graduated instruments, which he constructed with his own hands. With these instruments, which consisted of a sexant, a quadrant 6¾ feet radius, and very large telescopes, he made numerous observations, the result of which appeared at Dantzic in the year 1647, in his work entitled "Selenographia, sive Lunæ descriptio, atque accurata, tam maculorum ejus, quam motuum diversorum, aliarumque omnium vicissitudinum phasiumque telescopii ope deprehensarum, delineatio: in qua simul cæterorum omnium planetarum nativa facies, variæque observationes, presertim autem macularum solarium et jovialium tubo specillo acquisitæ, figuris sub

* "The Bœotians," says Pausanias, "have a tradition that Hesiod only wrote the poem of the Works and Days."

aspectum ponuntur; necnon quam plurimæ astronomicæ, opticæ, physicæque quæstiones resolvuntur. Addita est nova ratio lentes expoliendi, telescopia construendi, et horum adminiculo varias observationes exquisite instituendi."

In 1650, he published an epistle to his friend Eichstad, on the eclipse of the sun, on Nov. 4th, 1649; and in 1652, appeared another epistle on the solar eclipse, addressed to Gassendi and Bullialdus.

About this time, Hevelius made the important discovery of the moon's libration, of which he gave an account in a letter to Riccioli, which was published in 1654, and entitled *De motu Lunæ libratorio in certas tabulas redacto.* In 1656 he published his *Dissertatio de Nativa Saturni facie, ejusque variis phasibus, certa periodo redeuntibus cui addita est Eclipsis Solis anni* 1656, *observatio et diametri solus apparentis accurata dimensio.*

In 1661, Hevelius had the good fortune to observe the transit of Mercury on the sun's disc: and in 1662, he published his observations, entitled "Mercurius in sole visus anno 1661, cum aliis quibusdam rerum cœlestium observationibus, rarisque phenomenis; cui annexa est Venus in sole pariter visa 1639, Liverpoliæ a Jeremia Horroxio, nunc primum edita, notisque illustrata. Accedit succincta historiola novæ ac miræ stellæ in collo Ceti certis anni temporibus clare admodum effulgentis, rarsus omnine evanescentis; necnon genuina delineatio paraselenarum et parheliorum* quorundam rarissimorum."

The reputation of Hevelius was now so great, that the illustrious Colbert recommended him to the notice of Louis XIV. who granted him a pension. A copy of the letter, in which Colbert announced this act of liberality to Hevelius, is preserved in the Royal Library at Paris. Hevelius shewed his gratitude by dedicating to Colbert his "Prodromus Cometicus, quo Historia Cometæ anno 1664 exorti cursum, faciesque diversas capitis ac caudæ accurate delineatas complectens, necnon dissertatio de cometarum omnium motu, generatione variisque phenomenis exhibetur," *Dantz.* 1665. A supplement to this work appeared in 1666, entitled "Descriptio Cometæ anno 1665, exorti cum genuinis observationibus tam nudis quam enodatis mense Aprili habitis; cui addita est mantissa *Prodromi Cometici*, observationes omnes prioris Cometæ 1664, ex iisque genuinum motum accurate deductum, cum notis et animadversionibus, exhibens."

In the year 1668, he published in folio, his great work on comets, under the title of "Cometographia, totam naturam Cometarum, utpote sedem, parallaxes, distantias, ortum et interitum, capitum caudarumque diversas facies, affectionesque, necnon motum eorum summe admirandum, beneficio unius, ejusque fixæ et convenientis hypotheseos, exhibens; in qua universa insuper phenomena, questionesque de cometis omnes rationibus evidentibus deducuntur, demonstrantur, ac iconibus æri incisis plurimus illustrantur; cumprimis vero Cometæ annorum 1652, 1661, 1664, 1665, ab ipso auctore summo studio observati.—Accessit omnium Cometarum, a mundo condito huc usque, ab historicis philosophis et astronomis annotatorum, historia, notis et annotationibus locupletata, cum peculiari tabula Cometarum Universali."

When this work was completed, Hevelius sent a copy of it to Dr Hooke, and to other distinguished members of the Royal Society. In return for this work, Dr Hooke presented Hevelius with a Description of the Dioptric Telescope, and the method of using it; and recommended it as preferable to the use of plain sights in astronomical instruments. In this way commenced the celebrated controversy respecting the use of plain and telescopic sights. Hooke maintained, that with an instrument of a span radius, the distances and altitudes of celestial objects could be measured to a second by telescopic sights; and Hevelius insisted, in his reply, that with a good eye, and great experience, he had obtained the same accuracy in the use of his instruments; and he sent eight distances between stars, for the purpose of being examined by Dr Hooke. Here the controversy was for the present terminated.

In the year 1673, Hevelius published in folio, the first part of his "Machina Celestis, organographiam, sive instrumentorum astronomicorum omnium quibus auctor sidera hactenus rimatus et dimensus est, accurata delineatio et descriptio pluribus iconibus æri incisis illustrata et exornata; cum aliis quibusdam tam jucundis quam scitu dignis, quæ ad mechanicam opticamque pertinent, animadversionibus, imprimis de maximorum tuborum constructione et commodissima directione, necnon nova facillima lentes quasvis ex sectionibus coni expoliendi ratione." Hevelius sent copies of this work to all his friends in England except Dr Hooke; who, in revenge of the affront, published in 1674 his "Animadversions on the First Part of the *Machina Celestis* of the honourable, learned, and famous Joannes Hevelius, together with an explication of some instruments made by R H." Lond. 4to. This work was characterised by the irritability of its author. It was written with that tone of arrogant superiority, which injured his own cause, and excited the highest resentment on the part of Hevelius. In the same year, Hevelius sent a letter to the Royal Society, containing a reply to the objections of Hook and Flamstead, and appealing to observation for the correctness of his opinions. He complained of the "bitterness and boasting" with which he had been attacked, and requested that the Royal Society would send some eminent astronomer to examine his instruments and method of using them. This reasonable demand was acceded to; and Dr Halley, who held nearly the same opinions as Hooke, was requested to repair to Dantzic. He arrived in that city on the 26th May 1679, and continued with Hevelius till the 18th of July. By means of a good instrument, furnished with telescopic sights, Halley compared his own observations with those of Hevelius; and he particularly attended to the successive observations made upon the same stars by Hevelius, with his large brass sextant. The result of this examination was highly favourable to our author. Halley left an attestation, dated July 8-18th, 1679, declaring himself "abundantly satisfied of the use and certainty of these his instruments and observations. And whereas he had before been always doubtful, that his observations by naked sights might as to some minutes be uncertain, and had therefore wondered why he declined the use of telescopic sights; he had, partly to gratulate the author's publishing of his observations, and partly to satisfy his own scruples, undertaken that journey, which he now considers as no small happiness, and declares himself abundantly pleased with it: and offers himself a voluntary witness of the almost incredible certainty of these instruments, as having seen with his own eyes, not one or two, but a multitude of observations of the fixed stars performed with his great sextant, even by divers observers, and by himself sometimes, though less expert therein, being often repeated, most accurately and almost incredibly to agree, and never to differ more than by an inconsiderable part of a minute."

In the year 1679, Hevelius published his "Machinæ Celestis Pars Posterior; rerum Uranicarum observationes, tam eclipsium luminarium quam occultationum planetarum et fixarum, necnon altitudinum meridianarum, po-

* These Paraselenæ and Parhelia are described in our article Halo, and represented in Plate CCLXXXVII. Figs. 4, 5, 6.

larium, solstitiorum et æquinoctiorum, una cum reliquorum planetarum fixarumque omnium hactenus cognitarum globisque adscriptarum, æque ac plurimarum huc usque ignotarum, observatis, pariter quoad distantias, altitudines, meridianas et declinationes, additis innumeris aliis notatu dignissimis atque ad astronomiam excolendam maxime spectantibus rebus, plurimorum annorum summis vigiliis indefessoque labore ex ipso æthere haustas, permultisque iconibus, auctoris manu æri incisis, illustratas et exornatas, tribus libris exhibens."

Hevelius had fortunately presented about 30 copies of this work to his friends; for before it was published, his property of every description was consumed by a dreadful fire, on the 26th September 1679. No fewer than seven houses, containing his money, plate, gold, silver, household goods, printing houses, great part of his library, the remaining copies of all his printed works, published at his own expence, from the year 1647 to 1679, and particularly his observatory, with all his optical and astronomical instruments, were completely reduced to ashes. Among the articles preserved were the latter part of his *Machina Celestis*, containing the observations of nearly 50 years, and his *New Catalogue of the Fixed Stars*.

A full account of this calamity, and of his dispute with Dr Hooke, were published in 1685, in his "Annus Climactericus, sive rerum Uranicarum et observationum annus quadragesimus nonus, exhibens diversas occultationes tam planetarum quam fixarum, post editam Machinam Celestem observatas, necnon plurimas altitudines meridianas solis, et distantias planetarum fixarumque, eo anno impetratas cum amicorum nonullorum epistolis ad rem istam spectantibus et continuatione historiæ novæ stellæ in Collo Ceti, ut et annotationum rerum celestium."

This work was the last which Hevelius published. Worn out with the infirmities of age, and with the labours of science, he died on the 28th January 1687, in the 76th year of his age. Hevelius left behind him the reputation of having been one of the most industrious and ingenious practical astronomers of the age in which he lived. The surprise which Halley expressed at the wonderful accuracy of his observations, must be felt by every person who examines them, and who considers that they are well made by unassisted vision, and that the instruments were constructed and graduated with his own hands.

Hevelius left behind him two complete works, and many other manuscripts. The first of these made its appearance in 1690, in folio, entitled "Prodromus astronomiæ, exhibens fundamenta quæ tam ad novum plane et correctiorem stellarum fixarum catalogum construendum quam ad omnium planetarum tabulas corrigendas omnimode spectant, necnon novas et correctiores tabulas solares, aliasque plurimas ad astronomiam pertinentes, utpote refractionum solarium, parallaxium, declinationum, angulorum eclipticæ et meridiani, ascensionum rectarum et obliquarum horizonti Gedanensi inservientium, differentiarum ascensionalium, motus item et refractionum stellarum fixarum, quibus additus est uterque catalogus stellarum fixarum, tam major ad ann. 1660, quam minor ad ann. completum 1700. Accessit Corollarii loco tabula motus lunæ libratorii, ad bina sæcula proxime ventura prolongata, brevi cum descriptione ejusque usu."

This work, which was published by his widow, contains the catalogue of 1888 stars. It was afterwards reprinted in the 3d vol. of Flamstead's *Historia Celestis*, and is incorporated in the catalogue of stars given in our article Astronomy.

In the same year appeared his other posthumous work, entitled "Firmamentum Sobiescianum sive Uranographia, totum cœlum stellatum, utpote tam quodlibet sidus quam omnes et singulas stellas, secundum genuinas earum magnitudines nudo oculo et olim jam cognitas, et nuper primum detectas, accuratissimisque organis rite observatas, exhibens; et quidem quodvis sidus in peculiari tabella, in plano descriptum, sic ut omnia conjunctim totum globum celestem exactissime referant: prout ex binis hemispheriis majoribus, boreali scilicet et australi, adhuc clarius cuique patet." This work contains 54 charts, representing the whole heavens.

Hevelius was elected a Fellow of the Royal Society of London in 1664, and contributed several papers to the *Philosophical Transactions*.

When M. Delisle passed through Dantzic on his way to Russia in 1626, he purchased all the manuscript observations of Hevelius, along with his extensive correspondence, forming seventeen folio volumes, four of which were occupied with his observations. These manuscripts contain much curious information respecting the history of astronomy. They were lodged by Delisle in the depot of of the marine at Paris. Those who wish for farther and more minute details respecting the life and writings of Hevelius, will find much information in a life of him, published at Dantzic in 1780 by Benjamin Leugnich, and entitled, *Hevelius, oder Anekdoten und Nachrichten von diesem beruehmten Manne*. Many particulars respecting our author will also be found in Bernoulli's *Travels in Prussia, Poland, and Warsovia*, 1782, p. 183. A figure of his mausoleum is given in Bernoulli's *Collection of Voyages*, tom. ii. 1781. See also the *Journal de Savans, Aout*, 1782, and Murr's *Journal Literaire, Nuremb.*

HEXACHORD *Major* of Galileo, is an interval of music, whose ratio is $\frac{16}{27}$, $= 462\,\Sigma + 9\,f + 40\,m$, or the *Comma-redundant major* SIXTH. See that article.

Hexachord *Major* of the Greeks, or hexachordon major of Holder, &c. has the ratio $\frac{3}{5}$, $= 451\,\Sigma + 9\,f + 39\,m$, or the *Major* SIXTH, which see.

Hexachord *Minor* of Didymus, has the ratio $\frac{81}{128}$, $= 404\,\Sigma + 8\,f + 35\,m$, or the *Comma-deficient minor* SIXTH, which see.

Hexachord *Minor* of Galileo, has the ratio $\frac{50}{81}$, $= 426\,\Sigma + 8\,f + 37\,m$, or the *Comma-redundant minor* SIXTH, which see.

Hexachord *Minor* of the Greeks, or hexachordon minor of Holder, &c. has the ratio $\frac{5}{8}$, $= 415\,\Sigma + 8\,\Sigma + 36\,m$, or the *Minor* SIXTH, which see. (ϱ)

HEXAGON. See Geometry.

HEXHAM, is a market-town of England, in the county of Northumberland, finely situated on the south side of the river Tyne, at the confluence of the north and south Tyne. The two long streets, of which the town consists, are narrow, and not well built; but the town contains some good houses. The road from Newcastle to Hallwhistle passes through one of the streets, and the other principal street runs at right angles to this. At the intersection of these streets stands the spacious market-place in a large square, with a convenient piazza for the butchers' market, which has moveable stalls, and which is well supplied with water from a fountain. The church of Hexham, which forms a part of its ancient monastery, founded in 1112, is highly ornamented in the inside, and contains many fine sepulchral monuments. This church was dedicated to St Andrew, and was much celebrated for its beauty and extent by ancient historians. It is in the form of a Greek cross. The tower, which is in the centre, appears low and broad, though it has a height of 102 feet. The architecture is Gothic and Saxon. A double gallery runs round the whole structure, opening with Saxon arches, each opening being composed of three arches, the middle circular, and the others pointed, with very light pillars. The nave was burnt down by the Scots in 1296, and nothing remains of it but part of its western door. The choir now forms the parish church, and is crowded with inelegant pews and galleries. The priory stood at the west end of the church; and not many years ago its cloister and chapels were to be seen. There are two ancient stone towers at Hexham, one of which is used as a session-house, and formerly belonged to the priors of Hexham. The other is situated on the top of a hill near the Tyne.

It appears from two Roman inscriptions, found in a crypt of the church, that the Romans had a station, or town, at this place; for it is obvious, that this was not the *Epiacum* of the ancients, as Horsley supposed. The crypt, where they were found, is a place fifteen feet by nine, and contains a number of carved stones, which seem to have once formed part of a Roman fortress.

The town is governed by a bailie chosen annually. The principal employment of the inhabitants consists in tanning leather, and in making shoes, hats, and gloves.

The following is a statistical abstract of the parish for 1811:

| | |
|---|---|
| Inhabited houses, | 729 |
| No. of families, | 1171 |
| Do. employed in trade and manufactures, | 639 |
| Males, | 2136 |
| Females, | 2719 |
| Total Population, | 4855 |

HEXHAM, Battle of. See England.

HEYWOOD, Jasper, D. D. a writer of the age of Queen Elizabeth, and son of the epigrammatist Heywood, whom we shall immediately have occasion to mention. He was born in London 1535, and studied at Merton College, Oxford; from whence, according to Wood, he was on the point of being expelled for his irregular life, when he resigned his fellowship. Soon after he repaired to St Omers, and entered into the Society of Jesus at that place. From thence he went to Diling in Switzerland, where he distinguished himself by his learning and zeal for disputing with heretics; so as to obtain the rank of doctor of divinity. In the year 1581, Pope Gregory the XIII. sent him at the head of the first mission of Jesuits to England, but her majesty shipped him off, with 70 of his associates, out of the kingdom; and, returning to Italy, he died at Naples, where the zealous catholic Joannes Pittseus contracted an intimacy with him, and speaks of him with great respect. He translated three of the tragedies ascribed to Seneca, viz. the *Thyestes*, *Hercules Furens*, and *Troas*, in the measure of the syllables, and from that circumstance has obtained a name in poetical biography. (*n*)

HEYWOOD, John, father of the preceding writer, was one of the earliest dramatic writers that England produced. Warton says of him, that he drew the Bible from the stage, and introduced representations of popular life, and familiar manners. He was born at North Mims, near St Albans, in Hertfordshire, and in his youth contracted an intimacy with Sir Thomas More, who introduced him to the patronage of the princess (afterwards queen) Mary. His jests, and musical talents, made him a favourite with Henry VIII. who frequently made him handsome presents. When Mary came to the throne, he was admitted to her most intimate conversation, and is said to have amused her with his diverting stories even in her last illness. On the accession of Elizabeth, being a bigoted catholic, he naturally anticipated the loss of his court favour; and, going into voluntary exile, he settled at Mechlin in Brabant, where he died in 1565.

As a poet, he was famous in his time, and his plays are still curious relics. One of them, *The Four P's*, is in Dodsley's *Collection*. His longest work is the *Spider and Fly*, of which honest Holingshed says, "that the author dealeth so profoundlie and beyond all measure of skill, that neither he himself that made it, nor any one that readeth it, can reach unto the meaning thereof." His *Dialogue of Proverbs*, and *Six Hundred Epigrams*, give us but a humble idea of the wit and conversation of our ancestors. (*n*)

HEYWOOD, Thomas. This author was an actor as as well as a writer, and flourished in the reigns of Queen Elizabeth, James I. and Charles I. The date of his birth and death, (we might almost add, the whole history of his life,) is unknown, except his profession and character as a writer. In the latter capacity he is distinguished as one of the most prolific that ever existed; for, besides his prose compositions of *The English Traveller*, *Apology for Actors*, &c. &c. he tells us, that the plays in which he had either a principal share, or wrote entirely, amounted to two hundred and twenty. Of this number, it is true, that but a few comparatively remain. Different reasons have been assigned for the loss of so many of them. It has been alleged, that they were lost from the desultory manner in which he wrote them, on the backs of play-bills and tavern bills, as he was a great frequenter of taverns; but the true reason seems to have been, that the managers, in those days, purchased the sole property of the copies of plays, and it was not their interest to let them be published till the public had been completely satiated with them; of course, when plays ceased to be attractive, the memory of them would perish, and the actors would not much trouble themselves about compositions, which, if they had been printed, might not have repaid the cost.

Of 23 of his plays that remain to us, there is one that ought especially to redeem his name from oblivion. This is, *The Woman killed with Kindness*. The interest of it is founded, like of that Kotzebue's *Stranger*, on a story of domestic infidelity, and the repentance that ensues; but it terminates more tragically, and with a severer moral lesson. Mrs. Frankland, the penitent, though forgiven by her husband, cannot forgive herself, and dies broken-hearted. In this, and in several other pieces, Heywood, though not highly fanciful nor poetical, and though he seems to have hardly possessed the common ambition of a poet—to be thought such,—is nevertheless exceedingly natural and touching. The last scene between Frankland and his wife is very touching. It concludes thus:

Acton, (*the brother of Mrs. Frankland*) How do you feel yourself?
*Mrs. Frank.* Not of this world.
*Frank.* I see you are not, and I weep to see it.
My wife, the mother to my pretty babes,
Both those lost names I do restore thee back,
And, with this kiss, I wed thee once again;
Though thou art wounded in thy honoured name,
And with that grief upon thy death-bed liest,
Honest in heart, upon my soul, thou diest.
*Mrs. Frank.* Pardoned on earth, soul, thou in heaven art free
Once more. Thy wife dies thus, embracing thee! (*n*)

HIBERNATION. See Hybernation.

HIERA. See Kammeni.

HIERES, is a town of France, in the department of the Var, about nine miles east of Toulon. It is situated in a delightful valley, about four leagues long and one broad, open on the south to the sea, and bounded on the north, east, and west, by lofty mountains. Between the northern and western chain is a narrow pass, which is the road to Toulon. At the sloping entrance of this pass, on the declivity of a mountain that defends the whole plain, is situated the town, which is built in the form of an amphitheatre. The summit of the mountain is bare, and is cleft in several places, to give it the appearance of a fortification from a distance. Towards the base of the mountain stands the modern part of the town, which contains the principal street, the square, and the inns; but it has a gloomy and dirty appearance. The old town, which stands on the highest part of the mountain, presents a heap of uninhabited ruins; but the suburbs, which skirt the mountains, are cheerful and clean, and have a neat and rural appearance.

Near the mouth of the small river Gapeau, which intersects the plain of Hieres, are the salt-pits, consisting of a number of small basins separated by canals. The houses of the superintendants, excisemen, and workmen, have the appearance of a little sea-port. The salt is sent to Toulon, Marseilles, and Genoa, and the annual revenue amounts to about 500,000 francs.

About four English miles from the town is the Etang, situated in the centre of an isthmus, running from the southern coast. It is about a league long, and half a league broad, and the three little islands in the middle of it contain a great number of aquatic birds. The eastern part of the isthmus joins the road of Hieres, and is called La Plage de la Munasse. The lower part of it is the peninsula Giens, which contains many interesting objects.

Hieres is celebrated for the mild temperature of its winters; but it is reckoned unhealthy from May to October.

At the chapel of Notre Dame, on a hill situated near the sea-shore, and about a league from the town, is a good painting of the Twelve Apostles, and a bas-relief, by Puget.

The garden of M. Fille is well worthy of being visited. Its annual revenue is about 24,000 francs. In the garden of M. Beauregard, which is excellent, a crop of artichokes sold, in 1793, for 1800 francs. The chief exports from Hieres are, oil, wine, fruit, vegetables, flowers, and salt, which are sent almost exclusively to Toulon and Marseilles. A thousand oranges are sold for 45 livres. Vessels are loaded in summer at the beach near the salt-works; but in winter, all the merchandize must be conveyed to Toulon by land. East Long. 6° 7′ 55″, and North Lat. 43° 7′ 2″. Population about 7000. See Christ. August. Fischer *Reise nach Hyeres, im Winter von* 1803 *und* 1804. Leipzic. 1806; and Millin's *Voyages dans les Departemens du Midi de la France*, tom. ii. chap. 61.

HIERES, Isles of, (the *Insulæ Arearum*,) are a cluster of three small islands in the Mediterranean, situated about four leagues from the town of Hieres. They are called Porquerolles, Porticros, and the isle of Titan. They were called Stoechades by the Marseillois, who first inhabited them. The most western of these is Porquerolles, which is the largest and best wooded, and contains 85 inhabitants. Porticros is three leagues farther to the east, and is more elevated and fertile. It has a haven, and contains about 50 inhabitants. The other island is about three quarters of a league to the east of Porticros. It has fewer inhabitants, and is less fertile than the rest. All these islands may be seen from the town of Hieres. They are defended by small forts, and are covered with lavender and strawberries. They are frequently visited by parties of pleasure from the town. See Fischer's *Reise nach Hyeres.*

HIERO. See Syracuse.

HIERO'S Crown. See Hydrodynamics.

HIEROGLYPHICS, (from ἱερος, *sacred*, and γλυφειν,) *to carve*, properly sculptures or carvings, (and hence, by an easy and obvious transition, *paintings* also,) symbolically denoting, by particular figures and collocations of external or corporeal objects, sacred, moral, and religious truths.

Hieroglyphics may be considered as a *species*, of which *symbol* is the *genus*; for hieroglyphics are a particular class of symbols, differing however from other symbols, as well by the nature of the truths of which they are the signs, as by the mysterious and recondite mode in which these truths are exhibited. The truths denoted by hieroglyphics properly relate not to common or trivial objects, but to things sacred or divine; and the mode of exhibiting these is designedly obscure and enigmatical, requiring sagacity and acuteness, as well as patient attention, to develope their meaning.

The origin of hieroglyphical writing has generally been derived from Egypt; and undoubtedly it appears to have been there that hieroglyphics first assumed the form of a regular system. But, in fact, the first steps in the formation and employment of hieroglyphic emblems may be traced as nearly coeval with the earliest attempts of mankind to communicate their thoughts by visible marks, in addition to articulate sounds. In such attempts, it seems plain, that the first, as being the most natural, way of accomplishing the end, would be by presenting a picture or delineation of the object to be denoted. To express a *man*, an *animal*, or a *tree*, the figure of the object would be drawn and exhibited. To intimate that a man had been slain by a wild beast, the figure of a man stretched on the earth, and the animal standing over him, would be formed; to indicate that a hunter had caught his prey, the picture of the man with the prey in his hands would be given. Such was probably the earliest mode of writing. It is the opinion of the best informed writers, that it prevailed among the Phœnicians, Egyptians, and other early communities; and we know with certainty, that it was in use among the Mexicans when invaded by the Spaniards,—intelligence of their arrival having been transmitted to the emperor in a picture, and even the history of the empire having been delineated by paintings upon skins, afterwards found in one of the temples.

This way of communicating thoughts, however, was, of necessity, liable to much inconvenience. It was often difficult, and generally bulky. To lessen the toil, and abridge the size of the picture, different modes of abbreviation were resorted to. The principal part of the object might first be made to stand for the whole; as the head for the man, a hand holding a weapon for a warrior. Next, the principal circumstance in a complicated action might denote the entire action; two or more hands, with weapons opposed, might denote a battle; a scaling-ladder, set against a wall, a siege. In a short time, a farther improvement would occur; to put the instrument of an action for the thing itself, as, we are informed by Hori Apollo, two feet standing in water represented the fulling of cloth. Nearly connected with this, was the practice of denoting the efficient cause by the effect produced; as harvest, by a sheaf of corn—winter, by a leafless tree—hostile incursion, by ruined buildings and dead bodies.

From these different kinds of contracted characters, the transition was easy to the third stage in the progress of writing; to make one thing represent another, where any resemblance sufficiently striking between the two objects could be perceived. To this mode of communication it became frequently necessary to have recourse. Intellectual objects of every kind; the passions and feelings of men; the moral qualities of actions admit of no direct delineation by picture, they must therefore be represented, if represented at all, by sensible objects, to which they either bear, or are supposed to bear, some resemblance. Under the view of such analogies, wisdom was signified by an eye; ingratitude, by a viper biting the hand that offered it food; courage, by a lion; cunning, by a serpent. This constitutes what may properly be termed the *symbolic* mode of writing. It is in some measure analogous to that stage in the progress of speech observed among all rude tribes, where figures, tropes, and metaphors, fill up a great portion of every harangue.

This mode of writing is founded on resemblances perceived or supposed; and as it is difficult to set limits to the power of imagination in discovering or figuring resemblances, it might be supposed that the symbolic mode of writing could be carried to an indeterminate extent. But in fact it has its limits; it must be understood, if it is to be useful at all; the resemblance, therefore, must be either obvious and discerned by mere intuition, or so generally perceived and recognised, that the persons to whom it is addressed may easily pass from the sign to the thing signified. If the resemblance be very recondite and remote, if the analogy is traced from qualities not generally observed, the symbolic writing becomes proportionally obscure, and to the uninstructed not even intelligible.

It is thus, by a natural progress, that we can trace the origin of hieroglyphics. Mere picture writing was an obvious invention; contraction of picture writing was probably taught by necessity: symbols required the exercise of imagination; at first, probably, plain and perspicuous, they soon became more complicated and obscure.

Among a people who had no mode of representing their thoughts but by means of figures or characters of this description, the very progress of knowledge, or the extension of enquiry beyond the mere objects of sense or immediate observation, could not fail both to add to the number, and augment the obscurity of the symbolic signs made use of. New discoveries, new truths, new subjects of thought, required appropriate and expressive symbols; these might either be drawn from objects not hitherto delineated, or figures previously in use might be employed, arranged in forms and collocations remote from their former delineations. In either way it would follow, that to persons unacquainted with the very subjects to which the signs related, the symbols, until explained, would present confused and unintelligible groups. It was in this manner that the universe, or universal nature, came to be denoted by a winged globe, with a serpent issuing from it; and a serpent itself was made to represent the divine nature, on account of its supposed vigour and spirit, its great age, and the reverescence ascribed to it.

Hieroglyphics then are only an extension of picture writing, adapted to remote or mysterious objects. The first use, even of the simple hieroglyphic writing, was to record the history, the laws, and civil polity of the community; not, as Bishop Warburton justly observes, to conceal knowledge, but in fact to preserve and communicate it. But afterwards hieroglyphics came to be employed for a very different use. From the very nature of such a mode of writing, it is easy to see how conveniently, in the hands of a set of men aiming at pre-eminence by the reputation of superior wisdom, it might be used either to conceal their knowledge, or veil their ignorance from the people. Enigmatic figures, explained only to the initiated, were admirably fitted for such an end; and where the situation and circumstances of the people permitted this mode of concealment, we might expect to find it introduced and carried on. The extent, however, to which it could be carried, must be determined by the character or by the peculiar institutions of a people. Where superiority in knowledge in any class of the community was small, and the separation of professions not very rigid, the opportunities of concealing knowledge would be few, and the use of enigmatic figures less frequent; but where distinctions were strongly marked, particularly where a separate class of men were set apart to the conducting of religious rites and ceremonies, there, if no counteracting circumstance occurred, the occasions and means would be numerous and readily embraced.

Upon these principles it is not difficult to discover in the situation and character of the Egyptian priesthood, the circumstances which, though they did not indeed produce the invention of hieroglyphics, certainly occasioned a more extensive use of them than prevailed elsewhere. The Egyptian priests were a separate class of men, closely united among themselves, but sacredly distinct from the people, at a time when the only mode of writing in Egypt was by pictures or symbolic signs. Their retired life, joined with the objects about which they were chiefly employed, gave them the means and inclination of carrying their researches into abstract truths farther than the rest of their countrymen; the fruits of these researches were denoted by peculiar, often by the most grotesque and capricious symbols, conveying a secret meaning only to the initiated. In no other community, probably, did the same opportunies occur. Among some communities the separation of the different classes was neither wide nor permanent, and even where they were, yet as soon as alphabetic or even character writing was introduced, the use of symbolic writing would be in a great measure superseded. Hieroglyphics from that period, cultivated only for sacred purposes by the priests from the love of mystery and concealment, would soon lose their meaning, and in time become wholly unintelligible to all but the priests and their disciples.

Such appears to have been the history of hieroglyphic writing. The nature of it has been already explained. The symbols made use of in it were formed by assemblages of various objects, plants, animals, parts of the human body, heavenly objects, terrestrial appearances; all these combined in groups, which being first probably put together upon fancied resemblances, could hardly be deciphered, after the secret of their composition was lost. Some learned men have supposed that the Egyptian hieroglyphics contained much secret knowledge; probably they contained but little, and to employ pains in deciphering them, would only be a waste of labour.

Hieroglyphics abound on the ancient monuments of Egypt; the great obelisk brought from Egypt to Rome, is full of such figures; and on almost all the obelisks now existing they are met with. Many curious hieroglyphic figures were engraved on what was termed the Isiack Table, a large black table, long preserved at Rome, and at the sacking of that city, in 1525, found by a poor tradesman, and afterwards removed to Mantua, where it disappeared at the capture of the place. It had been previously engraved, and a plate of it is given in Montfaucon's *Antiquities*. Many Egyptian hieroglyphics were also engraved on gems, and small figures, which are still to be met with in cabinets. Hieroglyphics, properly so called, seem to be almost peculiar to Egyptian antiquities; the uncouth and distorted figures of some of the Hindoo gods have been conjectured to constitute significant emblems, somewhat of the nature of hieroglyphics; but it appears to have been in Egypt alone that they were extensively employed; a circumstance that may easily be accounted for upon the principles already explained.

Sir John Marsham supposes hieroglyphics to have been the origin of the worship of animals; the figure and the thing signified being, as he supposes, so connected, that both began to be held equally sacred. This is by no means improbable, though no direct proof of it is to be had. It seems certain, however, that hieroglyphics were often engraved on gems, as a kind of magical spell; these gems were termed Abraxas; they were exhibited by certain corrupted Christians, natives of Egypt, who had mixed a great deal of Paganism with their Christianity: many of them are still to be met with in the cabinets of the curious. These abraxas were superseded among the superstitious orientals by talismans.

The subject of hieroglyphics has been frequently treated of. Among the ancients, *Horus Apollo*, or *Horapollo*, wrote a treatise expressly on the subject. In modern times, one of the most laborious writers on hieroglyphics was the learned Jesuit Kircher. His *Oedipus Ægyptiacus* contains a great collection of curious particulars; but his explanations are fanciful, and indicate little judgment. In the second book of Montfaucon's *Antiquities* is given a general account of hieroglyphics, illustrated with accurate engravings. By far the most ingenious and philosophical account, both of the history and nature of hieroglyphics, is given by Warburton in the 4th book of the *Divine Legation*. The Bishop has not, however, been careful to distinguish between emblems in general, and hieroglyphics properly so called. Dr E. D. Clarke, in his *Travels* lately published, maintains, but by no means upon certain grounds, that the hieroglyphic characters were the letters of an ancient alphabet, and the more compound forms probably a series of monograms. (δ)

HIEROGRAMMATIST, (from ιερος, *holy*, and γραμματιστης, *a writer*,) an order of priests among the ancient Egyptians. To them was committed the care of the hieroglyphics, the exposition of religious doctrines, and the superintendance of the Egyptian learning in general. They were regarded as a kind of prophets; and to establish their reputation for this, they made use of their knowledge of the heavenly bodies, or meteoric phenomena, to impose upon the people. They were always near the person of the king, to whom they were next in dignity, and were exempted from all civil employments. When Egypt became a Roman province, they fell into total neglect. (δ)

HIEROMANCY, the art of divining futurity from observing the sacrifices when in the act of being offered up. See Divination and Sacrifice. (δ)

HIGHGATE, is a village in Middlesex, about four miles north of London, delightfully situated on the top and sides of one of the highest hills in the county, commanding the most beautiful and extensive prospects over Essex, Surry, and Kent, in one direction, and Hertfordshire, Bedfordshire, and Buckinghamshire, in another. It consists principally of the villas of the opulent merchants, &c. of London, and its buildings are equal, if not superior, to any in the neighbourhood of the metropolis. In order to avoid the steep hill, it was proposed to cut a tunnel through it, which was begun in 1808. The roof of it, however, fell in after the work had made some progress, and it was found necessary to make an open cut through the hill. This great improvement is now completed; and the London road passes below an arch, which it became necessary to build for the purpose of carrying a cross road over the cut.

HIGHLANDS. See Scotland.

HILDESHEIM, is the name of a German bishopric, founded in 822 by Charlemagne. It extends about 50 or 60 miles from east to west, and about 35 from north to south, and contains about 54 square German miles. The soil of the greater part of the district is good, and produces abundance of corn, flax, hops, and vegetables. The southern districts are hilly, and covered with forests; some of the hills containing excellent quarries and iron mines. The wood is principally oak, beech, ash, and birch. The diocese contains 16 bailiwicks, 75 manors, 13 towns, 234 villages, and 85,000 inhabitants, with an annual revenue of 250,000 rix-dollars. The principal towns are Hildesheim, Peina, Rosenthal, and Marienburg. After the secularization of the diocese in 1803, it was given among the indemnities to the king of Prussia. After the peace of Tilsit, it formed part of the kingdom of Westphalia.

HILDESHEIM, or Hillesheim, the *Bennopolis* of the ancients, is a town of Germany, and the capital of the diocese of the same name. It is situated on a rugged declivity, watered by the river Innerste; about six leagues S. E. of Hanover, and 10 W. S. W. of Brunswick. The town is tolerably large, but is irregularly built, and old fashioned. It is divided into the Old and New Town, which were united in 1583. The principal public buildings are the Cathedral, Holy Cross Abbey, the Gymnasium Andreanum, about eight Protestant churches, and several monasteries. The Cathedral belongs to the Roman Catholics, and its bishop was the only catholic one in all Saxony. It is a richly ornamented Gothic building, and contains among its antiquities the celebrated Pagan monument of Irminsal, which fronts the great choir. It is a column which serves to support a chandelier of several branches. Population 12.600.

HIMALEH, or Himalaya mountains, the *Emodus*, *Himaus*, or *Imaus*, of the ancients, is a stupendous range of mountains, which bound Hindostan on the north, and separate it from the country of Great and Little Thibet. In East Long. 76°, and North Lat. 34° 30′, the Himaleh range joins the mountains of Cashmere on the west, the northern range of the latter being as it were a continuation of the former. The Himaleh mountains being supposed to commence at this point, take a S. E. direction to Bootan, and form the boundary between that country and Thibet, in about 90° E. Long. and 28° N. Lat. stretching still farther to the east they terminate to the north of Asham. The river Burram-pooter is supposed to wind round the eastern extremity of the range about 95° of East Long. It appears from Col. Crawford's observations, that one of the peaks of Himaleh, seen from Patna, is more than 20,000 feet above Nepaul, or about 25,000 feet above the level of the sea. The country declines in height from the summit of these mountains to the south, the surface being irregularly mountainous to the borders of Bengal, Oude, and Delhi, where the plains begin, which stretch to the sea. Several of the tributary streams of the Indus, and probably the Indus itself, have their origin from the western side of these mountains. It is supposed that the sources of the Sanpoo, or Burram-pooter, and its tributary streams, are separated only by a narrow range of snow clad peaks, from the sources of the streams which form the Ganges. See Rennel's *Memoir*, and *Asiatic Researches*; Hamilton's *Gazetteer*; and our articles India and Thibet.

HINCKLEY, is a town of England, in Leicestershire, situated near the borders of Warwickshire. The town is divided into the *Borough* and the *Bond* without the liberties. The limits of the borough were formerly those of the town, which has been extended by the successive addition of four streets, the Bond End, the Castle End, the Stocken Head, and the Duck Puddle. The parish church is a neat large structure, with a modern built spire, erected in 1788, on the old tower. The body of the church seems to have been built about the 13th century. Its length, from the chancel to the west door, is 66 feet, and its width near the chancel about 80 feet. There are three other places of worship, and a Roman Catholic chapel. The town-hall, school-house, and ball-house, are very curious, but in a ruinous state.

Hinckley was once of much greater extent, and was encircled with a wall and deep ditch, traces of which are still to be seen. The part called the Jewry-wall is said to have been part of the temple of Janus. There is near the river a mount, supposed to have been a Roman fortification; and near the church are the ruins of a bath, with three mineral springs. Tesselated pavements, and other Roman antiquities, have been discovered here. This town is said to form the middle of the highest ground of England, and commands a view of no fewer than fifty churches. Its principal manufacture is that of coarse stockings of cotton, thread, and worsted. A larger quantity of stockings is supposed to be made here than in any town in England. The number of frames in the town and neighbourhood is computed at 1200, which give employment to nearly 3000 persons. The town is likewise noted for the goodness of its ale.

In 1811, the parish of Hinckley, including Dadlington and Stoke Golding, contained

HIPPARCHUS. See ASTRONOMY.

HIPPIAS. See ATHENS.

HIPPOCRATES, commonly called the Father of Physic, was the most renowned physician of ancient Greece, and the oldest medical writer of whom there are any authentic works now extant. He was a native of the island of Cos, which had been long celebrated in the annals of medicine, being the seat of one of the schools founded by the Asclepiades or descendants of Æsculapius. Hippocrates himself belonged to that family, and is reckoned by his biographers the 18th in a direct line from that personage. Among the number of his ancestors was Podalirius, the son of Æsculapius, who, along with his brother Machaon, followed the Grecian army in the Trojan war. His genealogy by the mother's side was equally honourable; as, in this line, he was the 20th descendant of Hercules. These genealogies may be fabulous, but they were credited among the ancients, and tended to increase the veneration in which the character of this great physician was held. Very few details of the life of Hippocrates have been transmitted to us; but the singular eminence of his character makes the biographer dwell with pleasure on circumstances, which, in the life of another man, would appear unworthy of attention. Hence a variety of unimportant rumours are stated, and the arguments for and against their probability are studiously discussed.

He was born in the first year of the 80th Olympiad, or 458 years before Christ, in the reign of Artaxerxes Longimanus of Persia, and was the contemporary of Socrates, Herodotus, and Thucydides. His father Heraclides, and his grandfather Hippocrates the elder, who were both eminent physicians, bestowed much pains on his education in literature and general science, as well as in medicine. He studied polite literature and eloquence under Gorgias of Leontium, a celebrated rhetorician. He is said to have studied the physical sciences under Democritus; but it rather appears that he was not acquainted with that philosopher till he was more advanced in life, and already celebrated as a medical practitioner. He enjoyed, from the circumstances of his ancestors, and the spirit of the place of his nativity, great incitements to medical studies, and great advantages for the prosecution of them. Under these favourable auspices, he acquired an early relish for the medical profession, and devoted himself to it ever after, with ardour and assiduity. Besides studying in the school belonging to his native islands, he studied the gymnastic medicine under Herodicus, by whom it was invented, and he travelled much in Greece, Thessaly, and Thrace, where he made many observations on the history of epidemic diseases. The greater part of his professional life seems to have been spent at Larissa, in Thessaly. One Andreas, who wrote on the history of medicine, assigns a less honourable motive for his peregrinations. He says that he absented himself, in order to escape from the punishment due to some larcenies which he had committed in the library of the medical school of Cnidos, where he was said to have transcribed some of the books, and then burned the originals. This account, however, entirely originated in the jealousy of the Cnidian school, to which Andreas belonged, and the precepts of which were controverted by Hippocrates. It is inconsistent with the sentiments of high honour which were conspicuous in all the conduct of Hippocrates. Others said that he fled, because he had copied some inscriptions in the temple of Æsculapius, detailing the cures of sick persons, who thus recorded their acknowledgments to that deity. This report is equally groundless with the other, and does not correspond with any thing that we know of the tendencies of ancient prejudice. He seems to have also travelled in Africa and Asia; but the chief scenes of his travels were on the European continent, where he frequently visited different cities and countries, for the purpose of relieving epidemic distempers, with which they were occasionally afflicted. While a dreadful pestilence prevailed among the Illyrians, he was earnestly invited by that people to favour them with the advantages of his medical skill; but, on inquiring into various circumstances attending that epidemic, he concluded that his services would be ineffectual. He declined the journey; and finding reason of apprehension that the same disease would extend to Thessaly and Greece, he sent his sons to these countries, for the purpose of preparing them to meet the visitation with proper precautions. In a plague at Athens, he is said to have contributed much to the health of the city, by ordering large fires to be lighted for purifying the air, and by burning various perfumes in private houses, in the manner of the Egyptians. His sons, also, gave material assistance. These accounts, however, do not well correspond with historical dates. The great plague of Athens, described by Thucydides, happened when Hippocrates was only thirty years of age, and could not have sons capable of giving medical directions. The inhabitants of Abdera, observing that their fellow-citizen Democritus had contracted much singularity of manners, that he had become addicted to immoderate and ill-timed laughter, and secluded himself from society, conceived him to be insane, and invited Hippocrates to go and pronounce a judgment on his case, and take him under his medical care. Hippocrates went, and finding Democritus a man of deep research, who engaged himself with unwearied assiduity in philosphical pursuits, pronounced him the wisest man in Abdera. Ten talents were offered to him on this occasion, but he declined accepting of any recompense.

Kings and princes are said to have made different attempts to engage him in their service. We are told, that Perdicas, king of Macedon, invited him to his court to cure his son of a consumption; and that Hippocrates discovered the whole complaint to consist in the workings of a secret passion which the young man cherished for Phyla, the mistress of his father. This story, however, coincides so exactly with the accounts of the cure performed by Erasistratus on Antigonus, the son Seleucus Nicanor, that we are forced to conclude it to be fabulous; and it must be confessed, that the other anecdotes of his life do not rest on the most satisfactory evidence. They are all derived from the same source, a collection of letters and other pieces, called τα εξωτικα, sometimes published with the works of Hippocrates.

Artaxerxes offered him large sums, and a splendid establishment, to induce him to enter his service during a destructive epidemic which desolated some of the provinces, and also the armies of Persia. Hippocrates refused the offer in a haughty style, expressing his contempt of barbarians, and the indignity to which he would find himself subjected by leaving the Greeks, to devote his services to that people. This unnecessary affront, arising from an excess of national pride, highly offended Artaxerxes, who then demanded of the inhabitants of Cos, that Hippocrates should be delivered into his hands, threatening them with the extremity of his vengeance in case of refusal. The people of Cos, however, were too honourable, and too much attached to their illustrious countryman, to yield to these intimidating threats; and Hippocrates remained unmolested.

The high character of this physician gave him, on one occasion, an opportunity of performing an important political service for his native country, which he tenderly loved. The Athenians threatened the island of Cos with a formidable invasion. Hippocrates solicited the assistance of the people of Thessaly and the adjoining countries, and at the same time sent Thessalus his son to Athens, to avert the storm by negotiation, and sage remonstrances on the baneful tendency of ambition. The exertions both of the father and the son were successful. The Thessalians, the Messenians, and the states of the Peloponnesus, engaged to espouse the interests of the island of Cos; and the Athenians, partly out of regard for Hippocrates, and partly from the apprehensions which so much resistance created, abandoned their hostile designs.

Hippocrates entertained a deep sense of the importance of the duties of the professional character. He spared no pains which were necessary for his own improvement, and the successful practice of his art. He was aware that medicine requires more assiduous attention than other employments; he exacted of all his pupils an oath, binding them to certain rigid principles of duty, and, among other things, to engage, that they would enter no house whatever, except for the purpose of relieving those who needed their assistance. This rule, if taken according to the strict meaning of the words, appears somewhat fantastic, as it supposes that the number of patients and of practitioners should always be nicely accommodated to one another. It shews, however, the abhorrence which Hippocrates had of any degree of negligence and frivolity in the medical character. He was ready at all hours to attend on a call; and submitted with as much willingness to all those minute attentions which were necessary for the welfare of his patients, as to professional offices which were apparently the most dignified. It also redounded to his honour, that his attention was not less directed to the gratuitous object of preventing, than to the lucrative employment of curing disease. Of this he has left a testimony in his writings, by treating on the subject of diet and of water. These features of disinterestedness would not merit great praise in modern times, in which they are so common, and are requisite to establish a character, and are therefore often either mimicked for this express purpose, or avoided, if they interfere with false and fashionable notions of dignity. They acquire greater lustre from the consideration of the different sort of manners which prevailed in the days of Hippocrates, as well as the complete superiority to intrigue, by which, in his conduct, they were accompanied.

His zeal for science and humanity was rendered efficient by his excellent talents, and the weight of his personal character. His sagacity in observing nature was a resource to him on every emergency; and the accuracy of his judgment led him to resist the useless frivolities which superstition had introduced into medical practice. Inviolable secrecy, justice, and good faith, marked the whole of his conduct. Uniting dignity with humanity in his deportment, he employed firmness or complacency on such occasions as called for the exercise of either quality. He spoke but little; and his language was masculine and concise. His actions were never conducted with agitation; no prescription was given with precipitance; no circumstances were neglected; nor was the result ever left in any degree to accident. If at any time he failed of success, from want of previous experience adapted minutely to any individual case, he acknowledged his failure in the most ingenuous manner. In his writings, he sometimes warns his readers against mistakes and errors which he himself had committed, and which were attended with fatal consequences. He exhibited in all respects a bright example of the qualities which he himself enumerates, with so much eloquence and good sense, as contributing to the perfection of the medical character. Hence his precepts on that subject acquire a double authority.

Hippocrates lived to a great age; some say 109, others, however, make it much less. He died at Larissa, and was buried between that city and Gyrtona. He left, among numerous other disciples, his two sons, Thessalus and Draco, both eminent physicians, and his son-in-law Polybus, who had been a favourite pupil, and afterwards became a celebrated teacher, and arranged and published the works of his friend and master. In statues and paintings Hippocrates is represented with his head covered, which is different from the usual manner of the Greeks, and was probably done on account of his having been so great a traveller, as that was the only description of individuals who were uniformly thus distinguished.

Hippocrates has always been regarded as the father of his art. The honour in which he was held, both during his life and after his death, was very high. The inhabitants of Argos erected a statue of gold to him. The Athenians more than once voted him a crown of gold, and initiated him in their great religious mysteries. This last was a favour very seldom conceded to strangers. Although he did not cultivate general philosophy, except as subservient to medicine, he exemplified so ably its spirit, that Plato, Aristotle, and others, looked up to him as a master, and sometimes commented on his opinions. Aristotle even followed him as a model of style. His works have been held in high esteem in all subsequent ages; they have been translated or commented on by Galen, Celsus, and numerous other physicians of the most eminent genius, both in ancient and modern times.

The treatises which have gone under his name are 72 in number; but they are not all of equal authenticity. Doctrines so contradictory are sometimes contained in them, as shew them plainly to have been the works of distinct authors. Some are probably of much more ancient origin than Hippocrates himself. Some are thought to have been written by his grandfather, who bore the same name: and several have been either much altered and interpolated, or entirely written by subsequent authors. Those which are universally allowed to be genuine are, "The Aphorisms," "The Prognostics," the first and third book "On Epidemics;" and the book "On the Influence of Air, Water, and Local Situation." Some are regarded as supposititious, because they deviate from the character of Hippocrates, as shown in the works now enumerated, both in solidity, method, and correctness of language; while others bear only in part the character of this master, and incline the critical reader to suspend his judgment of their authenticity. These last seem to have been such as Hippocrates left in an unfinished state, or the substance of notes or copies taken from his prelections by his pupils. Such are "The Four Prognostics;" "The Predictions;" the 2d, 5th, 6th, and 7th, books "On Popular Diseases;" that "On Diet in acute Diseases;" the books "On the Parts of the Human Body;" "On Aliment;" "On the Recoveries that happen on critical Days;" and "On the Humours." There is considerable difficulty, however, in deciding in the negative respecting the works said to belong to a particular author. We may give a judgment on the positive authenticity of certain performances, which bear the stamp of the genius and manner of a masterly writer. But such writers often produce works which are not equal to their genius, works which have been written under inauspicious circumstances, which have diminished their attachment to their subject, impaired their confidence in themselves, and obstructed the full exercise of their talent. Great differences may also depend on the period of life. Juvenile performances may be comparatively lame or volatile, and old age brings along with it a decay of the mental powers, which may appear in the literary performances to which it gives origin. Differences of the time of life will sometimes also account for inconsistencies of doctrine, produced by changes of opinion, which have taken place between the times at which different works have been composed.

The principal editions of the works of Hippocrates in the original are, those of Aldus at Venice in 1526; and of Frobenius at Basle in 1538, both in folio.

The editions of Greek accompanied by Latin translations are, those of Hieronymus Mercurialis, at Venice, in 1578; of Zwinger, at Basle, in 1579; of Anutius Foësius, at Francfort, in 1595; of J. A. Vander Linden, at Leyden, in 1665; of Renatus Chartrier, with the works of Galen, at Paris; and of Stephen Mack at Vienna, in 1743, 1749, and 1759.

The editions of Latin translations, without the original, are that of Cratander at Basle, by several translators, in 1526; of M. F. Calous, at Rome, in 1525, from MSS. in the Vatican; of J. Cornarius, at Venice, in 1545; and that of Anutius Fœsius, at Francfort, in 1596, in 8vo, by Wechel.

As Hippocrates was the first author who applied philosophical reasoning to medicine, the sect of the Dogmatists looked up to him as their head. But he did not cultivate theory to the exclusion of observation and experience: he was one of the most accurate observers that any age has produced, and his reasoning has much less mixture of error than might have been expected, from his deficient knowledge of anatomy, and the want of good logical methods at the time at which he wrote.

He gave a general theory of the formation and conservation of the universe, in conformity to the doctrine of the four elements; and he applied the same doctrine to account for the formation of the human body. In explaining the doctrines of health and disease, he acknowledged a general active principle, which he called *nature*, to which he ascribed the attribute of justice. This agent he considered as the cause of nutrition in the animal economy, by attracting what is good, retaining and preparing it, and rejecting what is superfluous and hurtful. The manner in which he accounts for the formation of the brain, the bones, the membranes, and all the various parts, has that air of absurdity which is universal in the physical philosophy of the ancients. His anatomy and physiology are not very fully contained in the works which have reached our times, and are evidently imperfect and fanciful. He divides the constituent parts of the animal economy into the solids, the fluids, and the spirits. The solids are the containing parts, the fluids the parts contained, and the spirits those which give motion to the whole. On this division, followed up with various subdivisions, he establishes his doctrine of the causes of disease. He divides the humours, for example, into the blood, the phlegm, the yellow bile, and the black bile, and distinguishes these by the possession or the want of heat or of moisture. The blood is warm and moist; the phlegm cold and moist; the yellow bile warm and dry, and the black bile cold and dry. The most valuable parts of the writings of Hippocrates are his histories of diseases. In delineating these, we find him a faithful and laborious observer of facts; hence he was deeply skilled in the diagnosis and prognosis of diseases. By far the greater part of his descriptions are still recognised as accurate by all who follow him in the path of careful observation. The article in which his observations are most deficient, is the pulse, which he so much overlooked, that some have supposed him altogether unacquainted with the changes to which it is liable. It was chiefly from the degree of heat, and the difficulty of respiration, that he judged of the state of a fever.

In the treatment of diseases, he inculcated a profound respect for the progress of nature, whom he regarded as the arbiter and judge of diseases, and as having certain salutary objects in view in the greater part of those successive changes in the constitution which they implied. This doctrine is in fact the same which has been maintained by various later theorists, under a different set of terms, and with slight modifications, such as the *archæus* of Van Helmont, and the *vis medicatrix naturæ* of Dr Cullen. The opinions of Hippocrates on this general point made him unwilling to use any means for interrupting the course of nature, as exhibited in the phenomena of disease: hence his practice is culpably feeble; and those whom an admiration of his genius has led to follow him closely, have been too prone to satisfy themselves with the exercise of tracing the course of diseases, rather than to resist their progress. These have been most numerous in France, where the study of the Greek medicine is treated as a separate branch of education. The Hippocratic method is denominated the method of expectation, and is extolled as rational and sure. But it deserves, in some measure, the sarcasm of the Roman physician Asclepiades, who called it a mere meditation on death, a solicitude to observe how a disease would terminate, and what length of time it would require to destroy the patient. Hippocrates indeed recommends some practical remedies for the purpose of aiding the good intentions of nature, and gently correcting some slight deviations incident to it. His precepts in this department are delivered with some formality, in conformity to the style of the early philosophy; but they are not characterised by that emptiness and unmeaning mystery which often prevailed, and they exhibit a justness of remark which was entirely his own. His general principle was, to cure contraries by contraries, cold by heat, heat by cold, evacuation by repletion, and repletion by evacuation. In idiopathic fevers, he began with the regulation of diet, which consisted in prescribing abstinence, with a very sparing allowance even of liquids, for three or four days, that no morbid matter might be added to the system, while nature threw off that which was already present. This was succeeded by the exhibition of various liquids till the fourteenth day, and it was not till a late period that any solid food was allowed. Medicinal preparations were also long deferred, and consisted of gentle laxatives and emetics. In inflammatory complaints his practice was more active; he used fomentations, blood-letting, and purging. He also gave some weak wine and aromatics, which are, it must be confessed, less correct prescriptions in diseases requiring the strictest anti-phlogistic treatment. In empyema (a collection of pus in the cavity of the thorax) he first drew out the patient's tongue, then poured a little irritating liquid, prepared from the root of arum, from hellebore or copper, into the trachea, for the purpose of exciting a violent cough, and thus discharging the purulent matter. He was also in the practice of shaking violently the patient's body, with a view to detach the matter from the parts to which it adhered. In diseases of the head, he first applied fomentations, and then excited sneezing for bringing off the phlegm.

In pharmacy he made extensive improvements. His preparations are diversified in their composition and consistence, so as to answer minutely the various purposes of external medicine. He paid great attention to the diversities of state, and the shades of morbid sensation in diseased parts, and nicely adapted to them the forms of his remedies. In this respect he may often serve for a model to correct the gross ideas of those who exclusively venerate the agency of powerful simples. As a surgical author, Hippocrates had great merit; though the vigour of his practice in this department sometimes exceeded the bounds of moderation. He placed great reliance on the revulsion produced by powerful discharges by means of blood-letting, and which was assisted by the use of cupping instruments; and when this failed, he formed extensive and deep ulcers, by the actual cautery. A full account of the opinions, theoretical and practical, of this ancient author, would fill a large volume. In this country, an acquaintance with them is, even among medical men, reckoned an object of curiosity rather than an attainment necessary to the physician; but the perusal of the works of Hippocrates himself has an excellent tendency to cherish in the mind of a professional man, that zeal for the objects of his art, and that keen and persevering attention to his duties, which renders his life most satisfactory to himself, and most useful to society. See Le Clerc's *Histoire de la Medicine*; Fabricius; also the *Life of Hippocrates*, by Soranus; and the introduction to Pinel's *Nosographie Philosophique.* (*H. D*)

HIPPOCRENE. See Helicon.

HIPPOPOTAMUS. See Mammalia.

HIRE, Philip de la, an eminent and industrious French astronomer, was born at Paris on the 18th March, 1740. His father was painter to the king, and instructed his son in the same art, particularly in drawing, and such branches of the mathematics as related to his profession. In the year 1761, three years after he had lost his father, De la Hire went into Italy to re-establish his health, and to study those fine models of painting and sculpture which every artist was ambitious to imitate; but, during the three years which he spent in that country, he discovered that he was more fitted to excel in astronomy and geography than in the fine arts, and he henceforth devoted his whole time to these interesting studies.

Upon his return to Paris, he was nominated one of the members of the Academy of Sciences; and in 1699, he was named *Pensionnaire Geometre.* Between the years 1678 and 1718, he published no fewer than *two hundred and forty-four* memoirs on almost every branch of mathematics and natural philosophy.

When the great Colbert had resolved to make a correct map of France, De la Hire was associated with M. Picard in this important duty, which occupied him for several years. In 1683, he was employed in continuing to the north of Paris the meridian which Picard had begun in 1669, while Cassini was employed in extending it to the south. The death of Colbert having put an end to this great undertaking, De la Hire was next employed in the formation of the great water-works with which Louis XIV. embellished his palaces. De la Hire filled also the situation of royal professor of mathematics and architecture, and was much esteemed among his countrymen. His name, however, is not associated with any great invention or discovery; and we are called upon only to admire the extent of his knowledge, and the persevering industry which he exhibited, both in acquiring it for himself, and in communicating it to others. The works which he published separately were,

1. Nouveaux Elemens des Sections Coniques. Paris, 1678, 1 vol. 12mo.
2. La Gnomonique. 1682.
3. Traité du Nivellement de M. Picard, avec des additions. Paris, 1684.
4. Sectiones Conicæ in novem Libris distributæ. Paris, 1685, folio.
5. Traité du mouvement des eaux et des autres corps fluides; ouvrage Posthume de M. Mariotte. 1686.
6. Ecole des Arpenteurs. 1689.
7. Traité de Mecanique. 1695, 1 vol. 12mo.
8. Tabulæ Astronomiæ Ludovici Magni jussu et munificentia exaratæ. 1702.

De la Hire died on the 28th April, 1718, and left behind him a son, Gabriel Philip de la Hire, who was much esteemed as a physician, and who published several papers on medicine and natural philosophy in the Memoirs of the Academy from 1699 to 1720.

# HISTORY.

In this article it is proposed, in the first place, to point out and explain the various advantages of the study of history; secondly, to enumerate those branches of study which ought to be entered upon, previous to, or contemporary with the study of history; thirdly, to give a brief and rapid sketch of the order in which ancient and modern general histories may most conveniently and advantageously be read; fourthly, to point out the order in which the history of particular countries may be read, so that they may be illustrative of one another; fifthly, to notice the different species of history besides what is emphatically called History.

I. With respect to the advantages which may be derived from the study of history, they are various and important:

if the value of that department of science is to be rated highest, which combines advantages of the most obvious and beneficial nature, history possesses a very strong claim to our attention and study. It is equally attractive to the unreflecting and philosophical mind: the former it interests by the excitation of novelty; the latter by the usefulness and importance of the general principles which may be deduced from the facts which it records. But perhaps the utility and value of this branch of study cannot be placed in a more obvious and conspicuous point of view, than by stating that it combines amusement of the deepest interest; the exercise and improvement of the best faculties of man; and the acquisition of the most important species of knowledge.

History, considered merely as a source of amusement, is infinitely preferable to novels and romances, the perusal of which too frequently debilitates the intellect by inflaming the imagination, and corrupts the heart by the infusion of what may justly be regarded as moral poison. Whatever valuable impressions are made upon the mind by fictitious adventures, the same in kind, though, perhaps, generally not equal in degree, are made by the perusal of history; and while works of fiction are not in their nature capable, in general, of any other uses than the authors had in view, which must necessarily be very limited; true history, being an exhibition of the conduct of Providence, has infinite relations and uses, and may be regarded as an inexhaustible mine of the most valuable knowledge. It has been very justly remarked, that "works of fiction resemble those machines which we contrive to illustrate the principles of philosophy, such as globes and orreries, the uses of which extend no farther than the views of human ingenuity; whereas real history resembles the experiments made by the air-pump, the condensing engine, or electrical machine, which exhibit the operations of nature, and the God of nature himself, whose works are the noblest subject of contemplation to the human mind, and are the ground-work and materials of the most extensive and useful knowledge."

But a higher use of history is, to improve the understanding and strengthen the judgment: by studying history, and examining into the causes and consequences of the events which it unfolds, the penetration is sharpened, the attention of the mind is fixed, and the comprehension enlarged: hence are acquired the faculty of discovering quicker, and that flexibility and steadiness so necessary to be found in the conduct of all affairs, that depend on the concurrence or opposition of other men. It is a great, but a prevalent mistake, to imagine, that history is calculated to enlighten the judgment only on those subjects which are connected with the welfare of the community at large; it is nearly in an equal degree calculated to enlighten the judgment on those that bear on individual utility and comfort. In this respect the advantages of history are more important than those we derive from our own individual observation and experience; for though the impressions made by the latter will be more vivid, and probably more permanent, yet the knowledge we derive from history is more correct, and consequently a better guide to us, in our intercourse with the world; for the examples which it presents are generally complete; the whole is before us; whereas in real life, every scene opens very slowly, and we consequently see but a small part of a thing at a time;—hence we are liable to be deceived in our judgment of it.

The history of Great Britain will sufficiently illustrate the truth of the preceding remarks; if entered upon merely as a source of amusement and interest, it is rich and valuable in this point of view. The rude and barbarous state in which this country and its inhabitants existed, at the period of the Roman conquest, contrasted with its present situation, when it has attained an infinitely higher rank in the scale of intellect and power than Rome ever reached, cannot fail to act as a stimulus to the curiosity, to learn the various events which occurred between these two states so diametrically opposite. Besides this general source of interest and amusement, which the history of Britain holds out, there are many particular periods in it, which are almost equally calculated to excite and gratify these feelings. This is considering the history of Great Britain in its lowest character; it further illustrates our preceding remarks, by the constant exercise which it affords for our judgment and penetration; so that it may be justly affirmed, that the faculties of the human mind will derive from its perusal a great accession to their strength.

But the great advantage to be derived from history,—and this advantage flows in the most direct manner, of the highest character, and in the utmost abundance, from the history of Britain,—consists in this, that by means of it we gain our knowledge of the mechanism of society; of the reciprocal influence of national character, laws, and government; of those causes and circumstances, that have operated towards the production and advancement, or the destruction and retardation of civil and religious liberty, and the various branches of science and literature. It leads to a knowledge of man in his social relations: it exhibits the various operations of different systems of polity upon human happiness. In a country which enjoys so great a portion of civil liberty as happily falls to the lot of the inhabitants of the British empire, almost every order of the community has its influence upon the measures of the legislative and the executive powers; consequently, a knowledge of history should be diffused to as wide an extent as possible among them. A familiar acquaintance with the history of their country was, in the best times of the Roman republic, held to be essentially requisite to qualify youth for stations of dignity, power, and profit, in the administration of public affairs. Hence the bitterness of the sarcasm, uttered by Marius, when he asserted, that, in his degenerate days, men of illustrious birth did not begin to read the history of their country till they were elevated to the highest offices of the state, that is, as he said, "they first obtained the employment, and then bethought themselves of the qualifications necessary for the proper discharge of it."

In this brief enumeration of the principal uses to be derived from the study of history, it is presupposed that historical facts are made the subjects of mature reflection. He who is satisfied with merely storing his mind with a multiplicity of events, even though those events may be of the highest class in point of importance, and calculated to establish or illustrate the most useful principles, will derive little profit from a great expence of time and labour.

II. The sciences which are of the most constant and general use in the study of history, so as to have deserved to be called its two eyes, are geography and chronology. Without the former, no reader of history can have any clear and distinct idea of what he reads. Moreover, by a knowledge of this science, we are able to verify many past transactions, which, if they ever happened, must have left indelible traces on the face of the earth. Many curious examples of this nature may be seen in Addison's Maundrels, and Shaw's Travels. With respect to chronology, it is absolutely impossible to form clear and distinct notions of the intervals of time, of the rise and fall of empires, and of the successive establishment of states, without some such general comprehension of the whole current of time, as may enable us to trace out distinctly the dependence of events, and distribute them into such periods and divisions, as shall place the whole train of past transactions in a just and orderly manner before us. For a further illustration of the uses of Geography and Chronology, as applicable to history, we refer our readers to those two articles in this work.

Another branch of study, which ought to be pursued along with the study of history, is what is called statistics; or that branch which comprehends an account of the sources of the wealth and power of different states, such as their population, habits of industry, agriculture, manufactures, trade, commerce, and finances. Unless we possess information on this head, it is obvious that we shall be much perplexed, and frequently led astray, in our endeavours to account for the comparative influence and exertions of different nations. Thus, for example, a person ignorant of the advances which Britain has made in agriculture, manufactures, commerce, and what may be called the economics of the state, cannot possibly satisfactorily account for the high rank which she holds in the scale of European nations,—a rank, to which, from the mere inspection of the map of Europe, she does not seem by any means to be entitled.

Another collateral branch of study ought to be that of the governments of nations; not a minute investigation of the various parts of their government, but such a knowledge of their general and leading principles, as would enable us to ascertain, how far, and in what respects, the influence and advances of each state might justly be attributable to their respective constitutions. In this point of view, also, Great Britain may be cited as an instance peculiarly illustrative of the justice and truth of our observations. A person who had made himself acquainted with the progress of this country in agriculture, manufactures, and commerce, and who beheld in them the sources of her wealth and power, would still be desirous of learning the causes, which had enabled her to make this progress so far beyond that of other nations; and of these causes, on investigation, he would find her free constitution to be the most prominent and operative. The observations which we have now offered, respecting the connection between the history and the statistics and government of a country, will be most fully and satisfactorily confirmed and illustrated by reading the articles Britain, *History of;* England, *History and Statistics of;* and Scotland, *History and Statistics of;* in this work. It is only within these few years, that the study of statistics has been much attended to; and we think we may, without the charge of vanity, or partiality, refer to this *Encyclopædia*, as connecting the history and statistics of the various civilized countries of the world more intimately and fully together, than they had been previously done in any work of the same nature.

Whatever illustrates the manners, customs, feelings, circumstances, and condition of the inhabitants of a country, in the various periods of its history, ought also to be studied by him who wishes to derive from history its highest gratification and its full advantage. The popular ballads of a nation, in this respect, ought to be perused; collections of the laws, ordinances, and internal regulations enacted in a state, during any particular period of its history, are well calculated for the same object; they give information respecting the condition of the great mass of the community, whether they were free or slaves; and also respecting the prevalent crimes and vices of the age, and what measure of punishment was necessary to expiate or repress them.

All these are collateral branches of study, which are connected with the proper and advantageous perusal of history in general; but those who wish to enter more minutely into the history of any country, and to gain access to as many sources of evidence respecting it as possible, may derive great advantage and assistance from the records of the courts of law. These furnish a vast variety of historical facts, most minutely investigated. To refer again to the particular instance of our own country: It may with truth be affirmed, that no one can form an adequate and correct idea of the gradual amendment effected in our institutions, and of the value of those constitutional principles and efforts from which those amendments have been derived, who has not read with attention the state trials. Treaties with foreign powers should also be perused; and the despatches of ambassadors, especially the confidential communications made by diplomatic agents. In the official letters of Barillon, published by Sir John Dalrymple and Mr Fox, the impolicy of Charles II. and of his unfortunate successor, is clearly traced; and in the papers of Sir Robert Walpole, as published by Mr Cox, a striking picture is exhibited of the difficulties incident to the administration of a free government. How much history may be illustrated by the publication of such official papers, or rather how inexplicable the facts it records may often be, if not illustrated by such papers, is proved in a most striking and interesting manner in the following instance. In the years 1775 and 1776, General Washington lay encamped before the town of Boston, at the head of a force far superior to that of the British, for the period of nine months, without striking a blow. The general's official correspondence with Congress, published in the year 1795, accounts for this dilatoriness, which, till this publication, was inexplicable. From it, it appears, that, during a great part of this time, he was so scantily provided with powder, that, had the British been aware of his situation, and marched to attack him, he would have been under the necessity of abandoning his position.

Biography also may be brought to the elucidation and assistance of history. In the lives of sovereigns, eminent statesmen, generals, and lawyers, peculiarities of character, prejudices, motives, and reasons for conduct, which history cannot detect, and other circumstances, are often brought to light, which serve to elucidate what is obscure, to connect what is disjointed and abrupt, and to account for what before seemed without an adequate and appropriate cause.

The history of many nations may also be elucidated by visible monuments, such as pillars, edifices, or mere heaps of stone; and by the names given to counties, towns, &c. Of the same nature with public monuments are national customs, in commemoration of remarkable historical events; such as the Athenians sending annually a ship to Delos; the paschal supper among the Jews; the Lord's Supper among the Christians; our making bonfires on the 5th of November, and carrying oak boughs on the 29th of May.

Coins and medals are also of great use, in the illustration of history. On ancient medals, a number of events have been recorded, so that they serve to confirm such passages as are true in old authors, to ascertain what was before doubtful, and to record such as were omitted. By means of them, Vaillant has been enabled to ascertain, in a very great degree, the chronology of three important kingdoms of the ancient world, viz. Egypt, Syria, and Parthia. Of Balbec and Palmyra, whose ruins are so famous, history scarcely makes any mention, and we have little knowledge of them, but what is supplied by medals and inscriptions. In modern times, coats-of-arms have been made use of for the purpose of distinguishing families. They must, therefore, be of great use in tracing pedigrees, and consequently in ascertaining persons and events in history. See Medals.

III. One of the most important directions for facilitating the study of history, is to begin with authors who present a general view of the whole subject. This is like sketching an entire outline, before any part of the picture is finished; and learning the grand divisions of the earth, before the geography of particular countries is studied. The principal advantage of this method is, that it gives a clear idea of the comparative importance, as well as of the connection, which the history of any particular country bears to the history of the world. The same advice is applicable to a person who proposes to study any particular period of the history of any particular country. He ought, in the first place, to make himself acquainted with the history of the country in general, and then study the history of the particular period. The history of the civil wars, during the reign of Charles I. will excite comparative little interest, and afford comparatively little instruction, unless an acquaintance with the previous history of England enables us to trace the causes of those wars, and the condition, feelings, opinions, influence and views, not merely of the different parties, but also of the different classes of the community.

A general acquaintance with the whole course of history, will render it less necessary to attend to the order in which particular histories are read; for if the reader is thus previously prepared, by a general acquaintance with history, he will be able to refer any particular history he engages in to its proper place in universal history. Indeed, after a thorough introduction to a whole course of history, it is comparatively a matter of little moment, in what order and connexion particular histories are read; for they will easily, and without confusion, range themselves in the mind in their proper place, and appropriate rank in point of importance.

There are several epitomes of universal history. While the custom of giving lectures prevailed in the foreign universities, the most celebrated were Tursellius's and Le Clerc's; but the use and popularity of these Latin epitomes has very considerably diminished, since the lectures have been given in the vernacular tongues of the respective countries of Europe. Tursellius's is a judicious and elegant performance; but by no means impartial or candid, where the interests of the Catholic church interfere. That of Le Clerc's is not liable to the same objection; but at the same time it must be remarked, that it is not entitled to the same praise. With these epitomes may be mentioned, as also written in Latin. Sleidan's *Introductio ad Historiam*, or a brief account of the Babylonian, Persian, Macedonian, and the Roman monarchies.

Bossuet's *Discours sur l'Histoire Universelle*, which may be regarded as an epitome of ancient history, as it comes down only to the period of Charlemagne, acquired a reputation at its first appearance hardly warranted by its merits, and which it has by no means supported. It is an elegant, and in some parts even an eloquent performance; but these are recommendations to history of very small comparative importance, when contrasted with credulity, bigotry, and partiality, with which this performance is justly chargeable. One of the most useful epitomes, upon the whole, is that written by Baron Holberg, in Latin, and translated, with improvements and additions, into English, by Gregory Sharpe. Its most prominent and serious defect is, that too little notice is taken of the history of Greece. None of these epitomes direct the attention of the reader to any other subject than the political part of history; they seldom or ever enter into the consideration of the causes or consequences of events; and never digress, if digression it may be properly called, into the consideration of the state of the arts and sciences, religion, laws, manners, government, and literature, during the different epochs of which they treat. In fact, they will by no means satisfy the mind that wishes to attain a proper introduction to history, as it is now generally written. For this purpose, the *Elements of General History, Ancient and Modern*, by the late Alexander Fraser Tytler, Lord Woodhouselee, ought to be read: In point of arrangement, due proportion and connection of parts, perspicuity and interest of style, a philosophical spirit, and the elucidation of the state of the arts and sciences, literature, &c. this work may be justly commended in the highest terms. *The Philosophy of History*, by Logan, and a larger work said to be written by the same author, but published under the name of *Rutherford*, should also be perused, preparatory to entering upon a regular course of history. Of the larger epitomes of ancient history, that of Rollin is the most interesting and complete: it is compiled with scrupulous fidelity from the best Greek and Latin historians: its style is fluent, and even elegant: its great fault is credulity, which prevents the author from discriminating in his recital of events between the marvellous and the true. The ancient history of the Abbe Millot, which constitutes the first part of his *Histoire Generale*, is more brief than that of Rollin; but, at the same time, more full than the epitomes we have mentioned above. The arrangement of this work is judicious; the style precise and compact. In his preface he informs his readers, that his plan is to seize those topics of historical narrative, which present the greatest portion of utility. He gives a bold, and in general a faithful and impartial sketch of events and characters; but the observations with which he relieves and intermixes his narrative, are frequently more distinguished for their obvious truth, than their originality or profoundness.

The reader having been thus prepared for a regular progress in ancient history, by the perusal of such parts of the above epitomes as confine themselves to that period, (for some of these epitomes, it may be observed, embrace modern as well as ancient history,) we shall now lay down a method by which the principal authors of antiquity may be read, so as to collect from them a pretty regular series of facts, which will comprise the history of Asia, Africa, Greece, and Rome, till the dissolution of the empire of Constantinople.

Herodotus is the earliest historian extant, next to the authors of the historical books of the Old Testament. His history comprises every thing he had an opportunity of learning respecting the Lydians, Ionians, Lycians, Egyptians, Persians, Greeks, and Macedonians, from the year 713 to the year 479 before the birth of Christ. Perhaps no author of history, ancient or modern, might be appealed to, as more fully illustrating the truth of the remark made at the beginning of this article, that, even in respect to amusement, history presents claims to attention not inferior to works of fiction. The great merits of this author are, his diligence, accuracy, fidelity, and impartiality. The accuracy of the geographical knowledge which he displays, is continually receiving confirmation from the discoveries of the moderns. His style is simple and elegant. His faults and defects are his digressive method, and his intermixture of fable. A more particular account of several events in the period of Herodotus' History may be extracted from the following authors: Justin, books i. ii. iii. and vii.; the 7th book of Xenophon's *Cyropædia;* the lives of Aristides, Themistocles, Cimon, Miltiades, and Pausanius, by Plutarch and Cornelius Nepos; and those of Anaximander, Zeno, Euripides, Heraclitus, and Democritus, by Diogenes Laertius, will illustrate not only the history of Herodotus, but also the state of manners and philosophy at that period.

Thucydides must be read after Herodotus. In his introduction he connects his history with that of Herodotus, by giving a summary view of the history of Greece, from the departure of Xerxes to the commencement of the Peloponnesian war. He proposed to write the entire history of that war, but his work reaches only to the 21st year of it. The method he pursues is directly the reverse of that followed by Herodotus; for his exact and scrupulous observance of chronological order, obliges him to interrupt his narrative, in a manner that is very painful and disagreeable to his reader. His style is uncommonly compact and dense; so that his meaning is frequently not brought out with sufficient fulness and perspicuity. His reflections are acute and profound, but more interesting to the politician than the philosopher. After the first book of this author, the 11th and 12th of Diodorus Siculus ought to be read; and, after the whole of his work, the 4th and 5th books of Justin, and the lives of Alcibiades, Chabrias, Thrasybulus, and Lysias, by Plutarch.

The 1st and 2d books of Xenophon's History of Greece complete the account of the Peloponnesian war, with the contemporary affairs of the Medes and Persians. After this the expedition of Cyrus, by the same author, should be read; and, lastly, the remainder of his History of Greece, which contains an account of the affairs of the Greeks and Persians till the battle of Mantinea, in the year 363 before Christ. All the historical books of Xenophon comprise a period of about 48 years. The style of Xenophon is remarkable for its elegance; his impartiality is undoubted; and his manner and plan form a happy medium between the loose and slightly connected excursions of Herodotus, and the extreme rigour of Thucydides. His account of the retreat of the Ten Thousand, in which he bore a principal part, is perhaps as interesting a portion of history as ancient or modern times can present, and is told in the most interesting manner. To complete the history of all that period of which Xenophon treats, the lives of Lysander, Agesilaus, Artaxerxes, Conon, and Datames, by Plutarch or Cornelius Nepos, and the 13th, 14th and 15th books of Diodorus Siculus, ought to be read. The continuation of the work of Diodorus Siculus brings the history of Greece and Persia down to the commencement of the reign of Alexander the Great, in the year 336 before Christ. The history of Alexander has been written by Arrian, Plutarch, and Quintus Curtius. After these authors, may be read the 18th, 19th, and 20th books of Diodorus Siculus, together with the 13th, 14th, and 15th books of Justin;—these contain the history of Greece from the year 323 before Christ to the year 301. At this period, the course of historical narrative may be traced from the 16th to the 30th books of Justin, and all that follow till the two last, which complete the history of Greece till it mingles with that of Rome.

The object of Diodorus Siculus was, by reading and travelling, to collect materials for an universal history, from the earliest account of things to the time of Augustus, when he flourished. But only a small portion of it has come down to us. Of 40 books, of which the entire work consisted, the first five, which bring the history of the world to the Trojan war, are entire; the next five are wanting; but from the 11th to the 20th inclusive the work is complete. The work of Justin is an abridgment of an universal history, written by Tropes Pompeius, who lived in the age of Augustus. It is written in a style of considerable perspicuity and force, and a due proportion and connection is observed among its several parts. Plutarch's lives of Pyrrhus, Aratus, Agis, Cleomenes, and Philopæmon, should be read to complete this portion of history.

As these authors contain not only the history of Greece, but that of all the nations of the world that were known to the historians; so the following course of Roman history must also be regarded as comprehending all that is now to be learned of the subsequent ancient history of all other nations.

The early part of the Roman history is treated in the most full and satisfactory manner by Dionysius of Halicarnassus. His entire work consisted of 20 books, and brought down the history to the commencement of the first Punic war; but of these, only the 11 first are now extant, and they terminate in the year 341 before Christ, after the dissolution of the decemvirate, and the resumption of the chief authority by the consuls. This author pays much more particular attention to manners, customs, and laws, than the ancient historians usually did; and, on this account, is peculiarly interesting and instructive. He is, however, very credulous; and his style, though pure, is harsh. To complete the history of the period of which Dionysius treats, the 1st, 2d, and 3d books of Livy, and the lives of Romulus, Numa Pompilius, Valerius Poplicola, Coriolanus, and Camillus, by Plutarch, should be read.

After Dionysius, by reading from the 4th to the 10th books inclusive of Livy, the history of Rome will be brought down to the year 292 before Christ. The entire work of Livy consisted of 142 books; but it has come down to us in a very mutilated and imperfect state, only 35 being left. This author is entitled to the highest praise for fidelity, impartiality, and the rich and eloquent grandeur of his style. A chasm occurs between the 10th and 20th books of Livy, which may be, however, in some measure, filled up, by the perusal of the 1st and 2d books of Polybius; the 17th, 18th, 22d, and 23d books of Justin; and Appian's Punic and Illyrian wars. From Polybius we may learn many curious and important particulars respecting the art of war among the ancients. His topographical descriptions of the places which have been the site of the remarkable events he records are uncommonly accurate. His style is harsh and involved; his reflections bear evidence of a strong and reflecting mind. After Appian should be read the remainder of Livy from the 21st book to the end, which brings the history of Rome to the year 166 before Christ. The lives of Hannibal, Scipio Africanus, Quintus Flaminius, Paulus Æmilius, Cato major, the Gracchi, Marius, Sylla, Cato minor, Sertorius, Lucullus, Pompey, and Brutus, by Plutarch, will not only serve to complete the history of Livy, but will also afford some striking particulars respecting the manners and state of society of Rome during the most interesting period of its history.

The war of Jugurtha, and the conspiracy of Cataline, which happened respectively 100, and 62 years before Christ, have been narrated by Sallust. The great merit of this writer is his impartiality at a time when prejudice and party spirit must have been very common and very powerful in Rome. His style is remarkable for its conciseness; and this quality is particularly conspicuous in the characters which he draws.

Most of the transactions in which Julius Cæsar was engaged, are best illustrated by his celebrated Commentaries, and the supplement to it compiled by Hirtius and others. In the Commentaries we may gain some very authentic and interesting information respecting the early state, manners, laws, and customs of those nations which now hold the most distinguished place in modern Europe. The merit of this work of Cæsar's is very high, in respect both to matter and style; the advantage which he derived, in respect to accuracy of information, from narrating his own exploits, is not, in a single instance, counterbalanced by vanity, partiality, or the concealment of his faults: his style is remarkable for its simplicity and ease. The secret history of this important period will be most clearly understood from a perusal of Cicero's Epistles, which may also be consulted for information respecting the state of society, manners, customs, &c. The fragments of the history of Dio Cassius contain a detail of the events, which took place between the period when Lucullus flourished and the death of the Emperor Claudian. In combination with this author may be read the elegant compendium of Velleius Paterculus, from the foundation of Rome to the reign of Tiberius, at which period he lived.

The Lives of the Twelve Cæsars, written by Suetonius, will prepare the way for the study of the works of Tacitus; and, together with the Epistles of Pliny, will afford a pretty clear insight into the state of society, and manners of the Roman empire at this period.

Tacitus wrote annals of the public affairs from the death of Augustus nearly to the end of the reign of Nero; but only a small portion of them have come down to us, viz. the four first books; a small part of the 5th; all the 6th from the 11th to the 15th; and part of the 16th. There is also a history, by the same author, which extends from the beginning of the reign of Galba to the end of that of Domitian. His work on the manners of the Germans is particularly interesting and instructive, as a preparatory study to the modern history of the northern and middle states of Europe. His life of Agricola is perhaps the finest specimen of biographical writing extant. Tacitus justly deserves the name of a philosophical historian: his insight into human nature, especially into the sources and workings of the worst passions, is deep and penetrating: his style is uncommonly dense.

On the times of servility that succeeded the period in which Tacitus lived, a dim light is shed by the works of Aurelius Victor, Herodian, the six compilers who are commonly known by the name of *Scriptores Romani*, Eutropius, Zosimus, Zonaras, Jornandes, Ammianus Marcellinus, Procopius, Agathias Nicetas, Nicephorus Gregoras, and Joannes Cantacuzenus. Procopius, &c. are distinguished by the appellation of the Byzantine historians. Their works relate to the history of the Greek or Eastern Empire to the period of its destruction by the Turks. Of all these authors, the only two that possess much merit are Herodian and Ammianus Marcellinus. The former wrote the history of his own times from the death of Antonine to the reign of Balbinus and Pupienus, A D. 238. His manner of narrating events is uncommonly engaging and happy. Every scene, with its causes and effects, is presented in the clearest and best point of view. Simplicity and elegance characterise his style. Ammianus Marcellinus wrote 31 books, from the beginning of the reign of Nerva to the death of Valens, in whose court he lived; but of those, the first thirteen, a superficial epitome of 257 years, are now lost. In those which are extant, he begins with Gallus Cæsar, about the year of Christ 353, and largely describes the actions of Constantius, Cæsar, Julian, Jovian, Valentinian, and Valens—a period of 25 years, bringing down the history of Rome to the year of Christ 378. He was the last subject of Rome, who composed a profane history in the Latin language. He well deserves the character and the praise which Gibbon gives him: "It is not without the most sincere regret (says that author) that I must now take leave of an accurate and faithful guide, who has composed the history of his own times, without indulging the prejudices and the passions which usually affect the mind of a contemporary." (Gibbon's *Roman Empire*, Vol. IV. chap. xxvi. p. 426. 8vo. edition.)

A most important series of events, connecting ancient and modern history, is supplied by Gibbon's *History of the Decline and Fall of the Roman Empire*. This work commences with a view of the policy which swayed the Roman cabinet in the time of Augustus. Rapidly passing on to the age of the Antonines, A. D. 180, it exhibits the extent and military force, the union and internal prosperity, and the constitution of the empire, at that period. It then begins to assume the form of a history in detail, which is brought down to the total extinction of the Roman Empire in the west; is afterwards continued to the taking of Constantinople by the Turks, A. D. 1453; and concludes at the establishment of the Papal power in the city of Rome, and the adjacent territory. The minute and extensive learning displayed in this important work not only supports the authenticity of the facts which it records, but also enables the author to discuss many correlative or incidental subjects, which elucidate either the manners, customs, laws, and state of society, at the different periods of which he treats, or those institutions that even at present characterize and distinguish the principal nations of Europe. His style is by no means chaste; the unremitting pomp of his periods fatigues his readers; and he deserves unqualified and severe censure, for the disingenuous manner in which he has insinuated his animadversions on the Christian religion. But, after all these deductions from the merit and value of this work, it is highly useful; and indeed the only work for the reader who wishes to obtain a clear, full, and interesting view of history, and the state of society between the period of the declension of the Roman empire and the infancy of the principal European states.

Those epitomes of modern history, which are connected with ancient history, have already been mentioned. We shall now notice such epitomes as are confined to modern history. A good general epitome was a work long wanting to the republic of letters. We have omitted to notice the Ancient Universal History in the former part of this article, because it is much too voluminous to serve as an introduction to a general knowledge of ancient history. The same remark applies to the Modern Universal History. Both of them are much more useful as books of reference, or for consultation, after a tolerably accurate and extensive knowledge of history has been acquired, than as introductory works; besides, the various portions of both are executed with very unequal degrees of merit. Voltaire's *Essai sur les Mœurs et l'Esprit des Nations* is rather a commentary on facts, an acquaintance with which is presupposed, than a detail of the facts themselves. The *Histoire Moderne* of the Abbe Millot is a judicious abridgment. It deserves the character of accuracy and impartiality; but, besides being liable to the objections that have been offered to the ancient history of the same author, it is too much compressed, for the extent and importance of the topics which it embraces. Russel's History of Modern Europe is a work of a much higher character, and much more valuable and useful to the student in every respect. Its merits appear to us not sufficiently known and prized. Probably, by those who have never read it, it is supposed that no great talents could be required or exercised in drawing up a mere abridgment of history. But the contrary is the fact: to judge from this work of Russel's, he must have been a man of considerable penetration, sound judgment, a philosophical spirit, and correct taste. His work is divided into two parts; the first embracing the period from the rise of modern kingdoms to the peace of Westphalia in 1648, and the second comprehending the events of history from the peace of Westphalia to the peace of Paris in 1763. A third part, bringing the history down from the peace of Paris to the treaty of Amiens in 1802, has been added by Dr Coote, who, though he has strictly adhered to the plan, has by no means attained to the merits of the original work. The subdivision of the plan is effected with considerable skill and ingenuity in a series of letters, in which the principal transactions of the leading European states are concatenated with as rigid adherence to chronological order, as was consistent with the mixed and fluctuating interests of those states. By passing over events which derived their importance and interest merely from the period in which they occurred, or the personages who were concerned in them, he has been enabled to give more room for those of a more permanent nature. As a repository of facts, therefore, judiciously selected, methodically arranged, and authenticated with sufficient learning and diligence, this modern history of Europe may justly be regarded as a work of very great utility; but it deserves higher praise. The causes and consequences of the most important events are traced with great ingenuity and penetration, at the same time that fanciful speculations regarding them are carefully avoided. The observations on the characters of the principal personages are distinguished by the vivid and faithful pictures which they exhibit. The progress of society from the rise of modern kingdoms down to the peace of Paris in 1763, exhibiting the manners of the people in their rudest state, and in their highest polish, is given at stated periods with much ability and research. The advances made in taste and science, and the usurpations of the ecclesiastical at the expense of the civil power, are clearly developed; and, being connected with the progress of war, politics, and legislation, exhibit, in a clear and conspicuous manner, the intellectual and moral improvement of European society. The style of this work is pure, elegant, and concise; and the reflections that are interspersed always illustrate and confirm the sacred principles of public and private justice.

This work will serve to exhibit the great and leading outlines of the events of modern history; and from Gibbon's Decline and Fall may be traced the origin of those barbarous tribes, whose chiefs, at different periods, making themselves masters of the various subdivisions of the Roman empire, laid the foundations of the modern kingdoms of Europe. The student having thus gained a general knowledge of modern history, as well as a more particular insight into the origin of the European states, ought, in the next place, to peruse those works which exhibit a general view of the history of modern Europe at various periods.

Much valuable information relative to one of the most important of the early periods of modern history is to be derived from the *Histoire de Charlemagne*, published by M. Gaillard in the year 1782, in four vols. 12mo. The general state of Europe in the 11th century is described by Mr Berrington in the second edition of the Lives of Abelard and Eloise. In the Abbe Sade's *Memoires sur la Vie du Francois Petrarque*, the author, by regularly indulging in details of circumstances with which Petrarch has little or no connection, has contrived to interweave into these memoirs a minute and elaborate account of the events which took place in Italy, France, and other parts of Europe, during the greater part of the 14th century. The history of this period may still be further illustrated by the Chronicles of Froissart, which, besides a minute detail of the transactions which occurred from 1326 to 1400, give a most interesting and amusing insight into the manners, customs, habits, and feelings of that period. A succinct narrative of general history is also to be found in Shepherd's Life of Poggio, which, relating to the origin of the famous ecclesiastical feud, the schism of the West, almost touches the period of Petrarch, and traces the principal occurrences which took place in Italy, and Europe in general, beyond the middle of the 15th century. The Life of Lorenzo de Medici, by Mr Roscoe, may be next perused: as Lorenzo's political connections were very extensive, his history embraces the principal occurrences which happened in the more civilized portions of Europe during his life, from 1448 to 1492. The succeeding period of general history is illustrated by the same author in his Life of Leo X. In this work, Mr. Roscoe enters fully into the state of Italy and Europe, which had so much influence on the fortune of that people, and which was also in no small degree modified by his actions. In both these works Mr Roscoe has given a copious history of the progress of literature and the fine arts.

The History of Charles V. next becomes the most prominent in the general history of Europe; and, with this view of it, it has been most ably written by Dr Robertson. The first volume of his work contains a view of the progress of society in Europe, from the subversion of the Roman Empire to the beginning of the 16th century, embracing the several heads of government, laws, manners, military establishments, and the political constitution of the principal states of Europe. The History itself comprehends the eventful period between the years 1500 and 1559, during which events took place which materially affected the state of society, and the advancement of literature, knowledge, and liberty, in Europe. The Histories of Philip II. and III., by Drs Watson and Thompson, may also be read with reference to a general acquaintance with the history of Europe during the period of their reigns, and to a knowledge of several events, which tended materially to change the relative situation and importance of the various states of Europe. Indeed, the political alliances and wars of these monarchs involve the interests of so many kingdoms, that their history displays the general topics of the history of Europe till the year 1621, the period of the death of Philip III.

Soon afterwards the French monarchy began to assume such a rank, and to connect itself with so many states, that its history ought to be perused, as throwing more light on the general history of Europe than that of any other kingdom at this time. Harte's Life of Gustavus Adolphus, and Scheller's History of the Thirty Years' War, also illustrate, in some degree, the history and state of the north of Europe about the same period; and bring down the narrative of events nearly to the age of Louis XIV. Voltaire's life of this monarch will conduct the reader to the period when, in consequence of the alliances formed by the English nation with various continental powers, the history of the world is strictly connected with that of our native land.

IV. Under the 4th division of this article, we proposed to point out the order in which the history of particular countries may be read, so that they may be illustrative of one another. "Nature," as Mr. Gibbon justly observes, "has implanted in our breasts a lively impulse to extend the narrow span of our existence, by the knowledge of the events that have happened on the soil which we inhabit, of the characters and actions of those men from whom our descent as individuals or as a people is probably derived. The same laudable emulation will prompt us to review and to enrich our common treasure of national glory; and those who are best entitled to the esteem of posterity, are the most inclined to celebrate the merits of their ancestors. The history of Britain, therefore, naturally will and ought to claim our highest interest. Under the article Bri-

TAIN, in this *Encyclopædia*, will be found a history of the Island from its first population by the Celts, until the arrival of the Saxons in the year 449. As our constitution, our national character, the tone of our manners and feelings, and our language, are, in a great measure, derived from our northern ancestors, the articles GERMANY and SCANDINAVIA ought to be read in connexion with the early part of the history of Britain. From the arrival of the Saxons till the union of the crowns of ENGLAND and SCOTLAND in the year 1603, the histories of these two countries are treated distinctly under the respective articles; but the connexion between them during the greater part of this period, was so close, though generally of a hostile nature, that their histories are necessarily mutually illustrative of each other. The history of FRANCE, also, given under that article, ought to be read, for the purpose of illustrating the histories both of England and Scotland; while an attentive consideration of the language, the manners, and the state of society in France, will afford elucidation, and give additional interest to the English and Scotch history during the same period. Under the article BRITAIN is given the history of the island, from the union of the crowns of England and Scotland to the commencement of the year 1812; and the most interesting portion of the foreign history of Britain, from 1812 to the last peace of Paris in 1815, will be found under the article FRANCE. A more full account of the war between Great Britain and her colonies, than is to be found under the former article, is given under the article AMERICA (*American United States.*) After the perusal of the histories of England, Scotland, and Britain, read in this order, and thus elucidated, the reader should peruse the history of IRELAND, given under that article: and as INDIA forms now such an extensive and valuable portion of the British empire, the history of it, under that article, ought to be read in connection with the history of the united kingdom.

If the student is desirous of entering more fully and deeply into the history of this country than the articles in this *Encyclopædia*, necessarily succinct, will enable him to do, Rapin will afford him a very elaborate, and in general a very faithful, history of England till the close of the 17th century; while, in Hume's History, he will find infinitely more philosophy, but far less impartiality and accuracy. The history of England, from the period of the Revolution, cannot boast any writer of standard excellence. In Henry's History of England, and Andrews' History of Great Britain, connected with the chronology of Europe, the literature, arts, and manners, religion and government, of the several periods, which these works respectively comprise, are elucidated.

The very early history of Scotland has been most elaborately elucidated by Pinkerton; the same author, and Lord Hales, have also treated, in a masterly and satisfactory manner, the history of this country during a less remote period. After the second work of Pinkerton, should be read Robertson's History of Scotland, during the reigns of Queen Mary, and James VI. till his accession to the crown of England; and Laing's History of Scotland from the union of the crowns to the union of the kingdoms. Leland's History of Ireland traces, in a masterly manner, the transactions which took place in that country, from the invasion of Henry II. to the treaty of Limerick in the reign of William III. Those portions of the history of this ill-fated and ill-used country since that period, which are particularly full of incidents, cannot yet be treated in an impartial manner. In the History of Wales, by the Rev. W. Warrington, all the facts are collected which can throw light upon the government, manners, and final subjugation of a people, still strongly marked by a peculiar character, manners, and customs.

Next to the history of the United Kingdom, the history of France claims the attention and investigation of the student, both on account of its connection with the history of these islands, and on account of the relative importance of that state in Europe. Under the article FRANCE will be found a sketch of its history, as full as the limits and nature of this work will allow, accompanied by a statistical account of that country, which, as we have already remarked, ought always to be read in conjunction with history. The early portion of the history of France admits of and requires elucidation, from a knowledge of the manners, laws, &c. of the ancient German tribes, nearly as much as the early history of Britain; the article GERMANY, therefore, may be profitably consulted for that purpose. After the affairs of France cease for a time to be intimately interwoven with the affairs of England, its history becomes connected with, and therefore may be elucidated by, the history of Austria under the Emperor Charles V. and by the history of Italy. During the 17th and the early part of the 18th centuries, the history of France requires a reference to the histories of the Netherlands and of Spain. From the commencement of the war between Britain and France in 1744 to the present time, the histories of the two countries are mutually illustrative of each other.

The history of Spain, perhaps, both on account of its relation to the histories of Britain and France, and on account of the importance of that kingdom in the scale of Europe, at least during a certain period, next claims the investigation of the student. Besides the article SPAIN, the article ARABIA may advantageously be consulted, in elucidation of the manners, customs, &c. and the early history of the peninsula. After the expulsion of the Moors, the histories of France, Spain, and Italy, from the end of the 15th to the beginning of the 16th centuries, are intimately connected. As the discovery of the new world happened at that period, the articles AMERICA, MEXICO, and PERU, ought to be consulted for an account of the transactions of the Spaniards there. Soon afterwards the history of this country becomes connected with that of the Netherlands. After the separation of the United Provinces from Spain, its history may be chiefly elucidated by the histories of Portugal, Italy, France, and Britain. The history of Portugal admits of little elucidation from the history of any other country except Spain; the articles AFRICA and ASIA, however, may be consulted for a brief account of their discoveries and settlements in these quarters of the globe.

As an introduction to the history of the German kingdoms and states, the article GERMANY ought to be perused: this will prepare the way for the history of Austria, illustrated in its progress by the histories of Switzerland, Italy, France, Spain, Russia, Turkey, Sweden, and the Netherlands: the history of Prussia, illustrated by the history of Brandenburgh, Russia, Austria, and France; the history of Bavaria, Saxony, &c. The account of the Reformation, given in the article ECCLESIASTICAL *History*, ought to be consulted, with reference not only to the history of Germany, but also to those of Britain, France, and the Netherlands, during the 16th and part of the 17th centuries. The history of Russia will receive elucidation from the histories of Austria, Prussia, Sweden, Poland, Turkey, and Persia. The article SCANDINAVIA ought to be consulted for a general view of the manners, customs, laws, &c. and early history of Denmark, Sweden, and Norway. These countries, besides mutually illustrating the history of one another, will receive elucidation principally from the history of Russia and Germany. Under the article NETHERLANDS, will be found the history of that country, not only while it remained undivided, but also of the United Provinces, and of the new kingdom, which has reunited the whole seventeen provinces. That portion of the history of this country, which properly relates to the United Provinces, will receive elucidation from the history of Spain, France, and England, during nearly the whole of the period, from the establishment of their independence till they were merged in the kingdom of the Netherlands. The comparatively pacific history of SWITZERLAND admits of illustration, in no important degree, except from the history of Austria, during the very early period of the establishment of its independence, till, like nearly all the other states of continental Europe, its history becomes involved in the revolutionary history of France.

The general account of ITALY ought to be consulted previous to the histories of Naples, Sicily, Venice, Tuscany, the Popedom, &c.; and these will be elucidated by the histories of France, Spain, Austria, and Turkey. The history of the Popedom, indeed, both in its ecclesiastical and civil character, is so intimately connected with the history of all the European kingdoms, (except Russia and Poland,) till the Reformation, that it ought to be studied carefully; for this purpose the article ECCLESIASTICAL *History* may be consulted. The history of Poland will be elucidated principally by that of Turkey, Austria, and Russia.

Respecting the histories of the kingdoms of Asia, Africa, and America, our notices must be very short. Of course, before the history of any particular country in any of these divisions of the globe is studied, the description of that particular division, under its proper head in this work, ought to be consulted. Turkey, from its connection with the histories of Austria, Poland, and Russia, claims perhaps the first notice. The history of Arabia, illustrated by the life of Mahomet, is an interesting object of study, not only on account of the conquests and literature of the Arabs, but also from the connection of their history with that of the Peninsula. Though the history of CHINA has little or no connection with the history of any European state, yet the peculiarities of its inhabitants must render its history interesting: Under that article will be found not only an accurate and well-proportioned abridgment of the history, but also a very faithful and detailed description of the manners, language, institutions, &c. of that singular country. Since the middle of the last century, the history of INDIA has become so intimately connected with the histories of France and Britain, and that country at present forms so large and valuable a portion of the British empire, that its modern history ought to excite considerable interest, even though its ancient history, and the character of its inhabitants, and their laws, institutions, &c. did not put forth strong claims to our attention. For an account of the histories of the other kingdoms of Asia, we must barely refer our readers to the articles of PERSIA, BIRMAN EMPIRE, JAPAN, THIBET, TARTARY, MALACCA, CEYLON, SIAM, &c. The history of the principal states of Africa will be found under the articles EGYPT, ABYSSSINIA, CAPE OF GOOD HOPE, ALGIERS, MOROCCO, TRIPOLI, TUNIS, &c. The history of the United States of America, as already mentioned, should be sought for under the articles AMERICA and BRITAIN; of the British colonies there, under the articles CANADA, NOVA SCOTIA, &c. and also under BRITAIN; of the Spanish colonies, under the articles BUENOS AYRES, CHILI, MEXICO, PERU, &c. and also under SPAIN; of the Portuguese settlements, under the head of BRAZIL, and also under PORTUGAL.

V. We shall now conclude this article with a brief notice of the different species of history, besides that which is emphatically so styled. History, strictly speaking, relates to the narration of the wars and political events of kingdoms; but besides this species of history, that which relates to the support which Christianity has received from the secular power; together with the benefits or disadvantages resulting from this support; and also to the internal administration of the church, its constitution and discipline, its doctrine and its worship; or, in other words, the history of Christianity, of its corruptions and reformation, and of the influence which its principles, or the conduct of its professors, have had on the political condition and affairs of mankind, may justly be regarded as very intimately connected with the species of history which we have been so fully considering. Ecclesiastical history, therefore, ought to be studied, not merely in its religious, but also in its political point of view. Whoever reflects on the power of the Pope for several centuries,—on the friendly relations or wars between the different states of Europe, which they brought about,—on the wars arising from the Reformation, and on the great and decided change in the political character and power of the mass of the people which that event produced, must be convinced that ecclesiastical history cannot safely be neglected even by the mere statesman. This article, therefore, ought to be carefully perused, both by itself, and in connection with the history of the different states of Europe.

The histories of the different arts and sciences are quite of a distinct class from political and ecclesiastical history; though, to the student of both of these, as well as to the man of science, they must be interesting and useful. The resources and the wealth of states depend mainly on their advances in the arts and sciences; and with respect to the connection of some of the latter with the state of religious knowledge, the history of astronomy is sufficiently explanatory. As one of the principal objects and advantages of history, strictly so called, is to gain an insight into the progress of man in political and individual happiness, surely an acquaintance with the advances which he has made in every species of knowledge, which secures his liberty, or multiplies his means of defence or enjoyment, must be interesting and important. Besides, whoever is desirous of satisfactorily accounting for the difference between ancient and modern nations, as displayed in their respective histories, and for the great and decided superiority of the latter, must look beyond mere political history, to the history of those arts and sciences, which were comparatively unknown to the ancients, and in which the moderns have made such wonderful advances,—advances that will be found, in a great measure, and nearly in every instance, accompanied by, if not really productive of, similar advances in national resources and political power. The copious histories of the arts and sciences, therefore, given in this work, under the respective heads of each art or science, ought by no means to be neglected by such as wish to read political history to advantage; and if they are perused in connection with the statistical account of each country, given along with its history, the causes of the comparative progress of nations in political liberty and power will be very clearly and satisfactorily traced. (W. S.)

HIVE. See BEE.

HOBBES, THOMAS, celebrated as a literary and philosophical character, but chiefly for the peculiarities of his moral and political doctrines, was the son of a plain unlettered clergyman of Malmesbury, Wiltshire. He was born on the 5th of April, 1588, at the crisis when this country was menaced by the formidable armada sent by Philip II. of Spain. His mother, powerfully affected by the consternation then so general over the kingdom, was delivered before the full time, in consequence of which Hobbes was remarkably delicate in his childhood. But he evinced a singular aptitude for learning, and attracted much notice by his proficiency at school. B fore the age of 14, he translated the Medea of Euripedes into Latin iambics. At this age, he went to Magdalene Hall, Oxford, where he distinguished himself by his application and genius. The Earl of Devonshire, wishing to profit by his talents, employed him as a companion and instructor to his eldest son, who was nearly of the age of Hobbes, and that family continued to patronise him as long as he lived. At an early period he was known to the celebrated Lord Bacon, with whom he was a great favourite, and to whom he acted as an amanuensis in translating some of his treatises into Latin. He travelled with his noble pupil in France and Italy, where he cultivated the society of Galileo and other celebrated characters, and studied the customs, institutions, manners, and learning of these two nations.

He now resolved to devote his life to the cultivation of polite literature, and his first publication was an English translation of Thucydides, which appeared in 1628. But his plans were disconcerted by the death of his pupil and friend. He soon after formed an engagement to travel with the son of Sir Gervase Clifton, with whom he remained for some time in France. In 1631, the Countess Dowager of Devonshire renewed his connection with her family, by putting the young earl, then 13 years old, under his care. He went with his pupil to Paris, where he studied mechanics and the laws of animal motion. On these subjects he had frequent conversations with Father Mersenne and with Gassendi, who was then engaged in an attempt to revive the physical doctrines of the Epicurean school. It was at the age of 40 that his attention was first turned to mathematical studies, in consequence of having accidentally looked into a copy of Euclid, where the enunciation of the 47th proposition of the first book arrested his curiosity. "This," he exclaimed, "is impossible!" He then rapidly went over the demonstration, and traced in a retrograde direction the preceding theorems on which the steps of the process were founded. The lovers of the mathematical sciences much regretted that he began these studies so late in life; as he evinced a happy talent for them, yet laboured under the disadvantage of an obstinacy of opinion, which might have been corrected by the more varied views unfolded during the pliant period of youth.

The ardour of his mathematical studies was in a great measure repressed, in consequence of the profound interest which he took in political affairs, in which he did not intermeddle as a busy politician, intriguing with individuals for the establishment of one party on the ruins of another, but conceived the design of producing a general impression by an open exposition of his opinions, which, though new and peculiar, he hoped to render popular, by the force of thought which he could display, and the strong evidences by which they were supported. When the political differences of the age were so strongly marked, it was a fair general conclusion that both parties were as likely to be wrong as any one was to be exclusively right, and that a man of vigorous thinking powers, who devoted much laborious meditation to his subject, might form a more accurate system than any maintained by his contemporaries. Nor was it unnatural for a young author to presume too much on the readiness of mankind to lay themselves open to conviction. These ideas he had cherished for a considerable time, and some represent him as having cultivated mathematics chiefly with a view to habituate himself to a close and steady mode of thinking.

His first political essay was a small tract, which was not not printed, but circulated in manuscript in the year 1640, during the sitting of the parliament in April, which was dissolved the following May, when the parliament and Charles I. differed so widely on the subject of the royal prerogative. This tract strongly asserted the pretensions of royalty, and condemned those of the parliament and the people as unjust encroachments. It occasioned a considerable sensation, and would have involved Hobbes in imminent danger, if that parliament had not been dissolved. This was the harbinger of the noted political works which he subsequently published, his book *De Cive*, and his *Leviathan.* Mainwaring, bishop of St David's, was sent to the Tower for preaching the doctrine of Hobbes; and the latter made a timely retreat to Paris, to prosecute his studies in the enjoyment of personal security. Here he returned to the society of Mersenne and Gassendi, to which was added that of Descartes. Afterwards, however, Hobbes controverted the doctrines of the latter on the subject of innate ideas, which terminated all their friendly intercourse.

In 1642, he published, while at Paris, a few copies of his book *De Cive.* He became acquainted with Sir Charles Cavendish, brother to the Duke of Newcastle, who admired his mathematical talents, and attached himself warmly to him as a friend and patron. In 1647, his fame in mathematics procured for him a recommendation to instruct the Prince of Wales, afterwards Charles II., in this branch of science. His fidelity and care in the execution of his trust secured to him the esteem of that prince, which continued ever after, though on some occasions prevented from being manifested by the obnoxiousness of his principles. In this year, a more complete addition of his work *De Cive*, was published in Holland under the care of Dr Sorbiere, to which two recommendatory letters were prefixed, one by Father Mersenne, and another by Gassendi.

In 1650, his book *De Homine* was published in London, containing a development of his doctines of sensation, particularly as illustrated by the mechanism of vision, with a dissertation on human speech, intellect, appetite, passion, action, and character: also another work, entitled *De Corpore Politico*, or "Elements of Law." In this and the year 1651, he published in London his *Leviathan*, a work in which his opinions on moral and political subjects were more completely embodied. After the publication of this work, he returned to England, though Cromwell was now at the head of the government, and lived at the Earl of Devonshire's country seat in Derbyshire. It is remarked that he lived in communion with a congregation belonging to the church of England, and regularly resorted to their place of worship. His assertion of the royal prerogative was not now construed to his disadvantage, as he had prudently intimated that his doctrine was applicable to any individual possessed of supreme power.

In 1654, he published his letter on "Liberty and Necessity," which occasioned a long controversy with Dr Bramhall, afterwards lord primate of Ireland. He advocated the doctrine of necessity. He sometimes says, he could not help being astonished that those who argue that men can act without constraint, forget that the determination of their actions depends on their will, and that it is not to the actions as separated from the will, but to the laws of the will itself, that our inquiries must be directed. He must be allowed to have added some precision to the nature of the arguments embraced in this controversy. He now began a dispute, on his part not creditable, with Dr Wallis of Oxford, which involved the greater part of mathematical science. Not content with attacking the doctrines of his adversary, he exposes with grovelling minuteness the inaccuracies of his language; and, though afterwards repeatedly refuted, to the satisfaction of all the mathematicians of the age, he persevered with unaccountable obstinacy in asserting his first opinions.

At the restoration of Charles II. in 1660, Hobbes removed to London, where he now reckoned himself safe. In the country, he was possessed of every advantage that books could supply, by the ample library of his patron, which was always enriched with every additional work that he chose to recommend; but he wished to enjoy the advantages of the conversation of the learned, which he found necessary to his habits of enjoyment, and to the full activity of his talents. Soon after he came to London, the king observed him from his carriage, and renewed his acquaintance with him: He fondly cherished his conversation, and settled on him an annual pension of 100*l.* But the personal favour of Charles was not sufficient to screen Hobbes from the censure of the parliament, which, in 1666, was publicly pronounced against his book *De Cive* and the *Leviathan*. This prince, though fond of absolute power, was a tool of the high church party, to which that controul on the part of the sovereign over ecclesiastical affairs, which Hobbes recommended, was extremely obnoxious. They professed the strictest attachment to hereditary monarchy, but certainly exacted it as a condition, that the king should maintain their hierarchy and forms as the established religion of the state; and, if we may judge from subsequent events, would have entertained but feeble objections to any prince capable of being seated firmly on the throne, who would shew himself most cheerful in assenting to this indispensable condition. Hobbes maintained, that the natural ferocity of man renders it necessary to vest the absolute power in one person, to whom the church and the consciences of the people ought to be subjected. Thus, he made the radical truth of any religious system a matter of little importance. To admit this, would be to acknowledge the church to be wholly a plastic mutable engine of government, and to compromise the dignity which she always asserts, of having her principles founded in immutable truth. A bill was also brought into parliament to punish atheism and profaneness, which he considered as aimed at him; for, though neither atheism nor the denial of Christianity were tenets maintained by him, he knew himself to be accused of them by the general voice, and therefore was somewhat uneasy. On this occasion, apprehending that his house would be searched, and his papers seized, he burned some of them, and particularly one which was the most obnoxious of all, a Latin poem on the encroachments of the Romish and reformed clergy on the civil power. The king was now obliged to withdraw from him all public expressions of his personal regard. He continued, however, to live in London unmolested; was held in high esteem among the learned; and was honoured by the visits of ambassadors and other illustrious foreigners, among whom was Cosmo de Medicis, then prince, and afterwards Duke of Tuscany, who procured his picture for his cabinet, and a collection of his writings for his magnificent library at Florence. Hobbes had it in contemplation to publish an elegant edition of his Latin works; but finding it impracticable in London, he had an inferior one executed at Amsterdam in 1668. In 1675, he published his English translation of the Iliad and Odyssey.

About this time, he took a final leave of London to pass the remainder of his days at the Earl of Devonshire's seat in Derbyshire, where he continued to prosecute his studies. In 1676, his dispute with Dr Laney, Bishop of Ely, on liberty and necessity, made its appearance; and, in 1678, his *Decameron Physiologicum*, or ten dialogues on natural philosophy; also, his *Art of Rhetoric*, and his *History of the Civil Wars, from* 1640 *to* 1660, which he entitled *Behemoth*, of the publication of which, however, his friend Charles II. who saw it in manuscript, did not approve.

His mental powers continued vigorous till his last illness, and his great delight consisted in exercising them. In his 85th year, he wrote an account of his own life in Latin verse, which evinced considerable activity of mind, though the execution of his task afforded no bright display of literary taste. In the following quaint conceit, for example, he depicts the circumstances of his birth:

> "Fama ferebat enim, sparsitque per oppida nostra,
> Extremum genti classe venire diem;
> Atque metum tantum concepit tunc mea mater,
> Ut pareret geminos meque metumque simul."

He continued even to study mathematics with great perseverance, and he died at the house of his noble patron in 1679.

The accounts given of his temper and private character are various, according to the channels through which they are communicated. Those whose doctrines he disputed, and whose writings and characters he reviled, drew along with them a number of partisans to stigmatise him as rude, acrimonious, and untractable. Of this temper we certainly perceive some traces in his writings; but we likewise find in them occasional proofs of a spirit of conciliation and candour, together with a sense of the bias which external circumstances gave to his writings. In the following terms he concludes his preface to his book *De Cive*: "If, in this treatise, you find any thing of questionable solidity, or any thing expressed with too great acrimony, remember that they are spoken not from party zeal, but a sincere wish for the peace of society; and by a man whose grief, so justly awaked by the distractions and calamities of his country, entitles him to a share of forgiving tenderness. He therefore craves, that you will, on such occasions, bear with his weakness, and not indulge towards him the extremity of your displeasure." He laid it down as a maxim, that it was unlawful to commence an abusive attack on any writer without provocation, but that, when first attacked in this way, he was entitled to make the severest retorts; and his practice shewed, that on such occasions he knew no bounds. He aspersed with the utmost scurrility the members of the Royal Society as a body, expressing his contempt for their attachment to experimental inquiry, and representing them as abandoning the use of their rational faculties.

At court he was a common object of banter, which he bore with good temper, and was remarkable for the felicity and fecundity of his repartees. To serious questions, however, he never gave a ready reply. If his opinion was asked on any point of philosophy or of political science, he gave a winding, computing, and diffident sort of answer, which, in a less noted man, might have been mistaken by the superficial for a mark of indecision of character, but in reality proceeded from his being aware of the multiplicity of circumstances to be taken into account, and the risk which there always is of running into error. All who cultivated his society pronounced him a delightful companion. Mr Wood, in his *History of the Antiquities of Oxford*, inserted this character of Hobbes: "He was a man, of whom (amidst the varieties of accounts, good and bad, that have been circulated) this may be most truly pronounced, that he had a most comprehensive and well replenished mind on universal science,—a mind which despised riches and secular honours, and was superior to the envy of the world. To his relations and others he was ever kind and beneficent. Among his companions, his conversation was cheerful, open, and free. By strangers he was held in veneration, as the first ornament of his country." This eulogium, however, was struck out of the work by Dr Fell, dean of Christ-

Church, through whose hands all works printed at the university-press were required to pass. The transaction was communicated to Mr Hobbes, who had a pamphlet, containing a full exposure of it, ready for appearing in London and Oxford at the same time with the work of Mr Wood. Hobbes was remarkable for vigour of nerve, and steadiness of intellect. He used to say, that in his most complicated arithmetical calculations he never mistook a figure; and with the same undeviating steadiness he prosecuted all his learned undertakings. The high value which he put on this natural quality, had probably some influence in rendering him impatient of opposition, and gave origin to the harsh features which some parts of his works bear.

According to the account given of him by Dr White Kennet, he was considered in the house of the Earl of Devonshire as a humourist, or unaccountable being; a character very readily acquired by a man who dedicates to study the hours by which those around him have their manners moulded by their general intercourse with others. His amusements, exercises, and social interviews, being subservient considerations, were dictated by his own thoughts; and though not resulting from an unaccommodating temper, appeared capricious, because they were singular. In this nobleman's house he was retained from gratitude and affection, rather than with a view to any sort of services, and he lived in ease and plenty without any official charge. His mornings were spent in violent exercise, such as running and climbing steep ascents, in which he exerted himself to fatigue. After breakfast, he went round the family, to wait on the countess, the children, and the visitors. Thus the time passed till twelve o'clock, when he had a little dinner prepared for him, after which he retired to his study, where he smoked, thought, and wrote for several hours.

Sensible that he was obnoxious to a powerful party, he was haunted with habitual apprehensions for his safety. The pension of the King was chiefly valued by him as a pledge of protection from persecution; and he had Lord Arlington and some other friends engaged to protect him at court whenever there was occasion. He disliked to be left in a house alone, some said for fear of being assassinated by his enemies, while others ascribed it to the workings of an involuntary superstition. When the Earl went from home, he always went along with him, even in his last illness, when he required to be conveyed on a feather-bed to the carriage, and survived the journey only a few days. He avoided all conversation on the subject of death. If, as has been supposed, he scarcely believed in a future state, yet he seems not to have been capable of looking forward to his dissolution with that placid indifference with which men generally look back to the period preceding their birth. He reckoned on the continuance of life when his constitution was too much worn out to justify such expectations; and when, in reply to some anxious inquiries, he was forbid to hope for a recovery, he lay in a state of silence and apparent stupefaction, which was concluded to be in a great measure produced by the state of his mind. The last words which he uttered in the full possession of his senses were, "I shall be glad to find any hole to creep out of the world by," which probably expressed a wish that his last moment should be exempt from pain and disturbance. He conformed to the Episcopal Church of England, and declared that he preferred that religion to all others; yet he had no confidence in the utility of religious services on his death-bed. On one occasion, during his residence in France, when his life was seriously in danger, he resented the solicitations of the Romish priests and the Protestant clergy to submit to some rite which would proclaim him a believer in their respective systems, and told them, that if they did not desist, he would expose the impostures of their whole fraternity, from Aaron downwards.

It is with the writings of Hobbes, and the opinions which he circulated, that the public is chiefly concerned. His writings were fitted to make a powerful impression at the time at which they appeared; but the character of society has subsequently so much changed, that they are now comparatively of little interest. His small treatise *De Homine* is regarded by the philosophical world as the best of his works. In this he, in some degree, advanced the science of optics, then in a rude state. His notions, though crude and inaccurate, are ingenious and interesting. His moral observations sometimes breathe the sage spirit of Aristotle. At one time he, like that author, condenses his meaning in a few words; at another he suddenly deviates into a style of extreme expansion. This chiefly happens when he applies his doctrines to the opinions and transactions of his own times. A celebrated living author (Professor Stewart) justly remarks, that Hobbes, whether right or wrong, never fails to set his reader a-thinking, which is the most indubitable proof of original genius.

To attempt to collect a system of moral, political, and religious doctrine from his works, would now appear ludicrous. In some parts his inquiries are shallow and deficient, most especially in his investigations of our ideas of morality and justice. He considers a regard for personal advantage as the only law of man in a state of natural liberty, and represents all the obligations of justice and good conduct to our fellows as the consequence of civil contracts formed under the influence of individual prudence. The laws, he says, are the foundation of justice; before them justice and injustice are unmeaning words. If this view of things had been advanced only as a general description of the actual condition of man under a total want of laws, as well as the absence of generous or deliberate reflection, and if he had considered pactions and civil institutions as the means by which men agree to execute beneficial ends, he could not have been greatly blamed; but he regards even civil compacts as the sole effect of the regard of each man for his own safety; and such feelings of kindness and compassion, as most loudly proclaim the social virtues to be a part of our original nature, are represented as arising solely from a reflection on the possibility that exists of experiencing in our own persons the evils which we deplore in others.

In forming this, and some other views, he appears to have been led astray by the desire of giving what appeared to him a palpable account of human affairs; but it partakes too much of those gross maxims which sometimes indecently obtrude on our notice, both in conversation and books, which foster our worst passions by boldly representing them as the necessary springs of human conduct. No doctrines can have a more destructive influence on those finer feelings which are connected with just reflection and the encouragement of exalting sympathies, but which require to be delicately cherished if they are to be preserved from pollution and degradation. The same love of palpability seems to have been the origin of that system of materialism, or rather that preference of the language of materialists, which appeared in the explanations which Hobbes gave of the origin and laws of thought. By representing justice as founded on positive law, he overturns the principles of jurisprudence itself, which must precede law, and determine the propriety of institutions. If he acknowledged the preservation of the general welfare to be a valuable end, it was certainly paradoxical to deny that a man, on his first interview with a stranger on an unknown shore, previously to the establishment of any mutual understanding, is under obligations to cultivate personal kindness, and to abstain from violence and domination. The boundaries of these early feelings, and the modes in which they may be best expressed, are not indeed easily defined, especially if we encounter distraction from the circumstance of a numerous population. Therefore it appeared the easiest method to pronounce them arbitrary, and in no degree binding, compared to declared promises, compacts, and promulgated laws. But men may differ both about the formation and the execution of laws, and how are their differences to be decided? "They must," says Hobbes, "choose a sovereign power, and to this their whole interests are at once committed." Such is the origin of regal government; and from this simple fact he draws the monstrous conclusion, that kings can do no wrong; that they must never be resisted; and that to their hands the lives, properties, and consciences of the members of a state must be perpetually and unconditionally entrusted. That such will be the state of mankind, if they are barbarous in their character, jarring in their views, or bereft of spirit; that it will even be worse than this, if they are subjugated by the power of a brutal master, who feels no obligation to consult their welfare, farther than as it is subservient to his imagined interest or the gratification of his caprice, is a fact too often exemplified in the history of the world: but to erect it into a principle that this *ought* to be the case, and that no efforts of mankind should be directed to the formation of any better state of society, is an idea which, in a reflecting mind like that of Hobbes, could only be generated by the miserable dissensions by which he was surrounded. In the days of Cromwell and the Charles's, the spirit of intolerance was active, extravagance contended with extravagance, and there seemed to be no possibility of terminating the scene of violence by a temperate discussion of principles, or a mutual adjustment of views; it was therefore necessary to still the passions by some powerful agent. The agent that occurred to Hobbes as the most suitable, was the exertion of absolute authority in the hands of the chief magistrate, and the perpetual establishment of this power seemed necessary for the prevention of future troubles. As a temporary expedient, he might have been pardoned for advancing such a position, even by those who dissented from him; but when he erects it into a universal principle, he must be regarded as an aggressor of the rights and interest of society, and a deliberate apologist of tyranny.

In theology Hobbes speculated with equal infelicity. Insensible both of the mysterious nature of his subject, and the reverence which it required, he examined it with a minute and daring curiosity, and pronounced his opinions in the same dogmatic spirit which characterises his other discussions. To retail his notions would be superfluous. Let it suffice to mention that, in conformity with his general theory of right and wrong, he asserts that the attribute of justice has no meaning as applied to the divine Being, who possesses uncontrolled power, and is not accountable to any superior. His comments on scripture cannot be read with interest by any class of men. The Christian must regard them as audacious and wild, and the infidel as tedious and unmeaning. Although, with his usual love of palpability, he explodes some mysteries, and attempts to reduce his subject to a few short and easy theorems, these are so repugnant to the conclusions which the slightest farther reflection would suggest, that their only tendency is to unhinge such religious views as his readers may have formerly entertained, without furnishing any thing satisfactory in their stead, or emancipating the mind from the wishes which it may have habitually cherished.

Hobbes will long be pointed to as an eloquent and remarkable writer, but rather fitted to excite wonder than to gain approbation. His intentions, however, are not deserving of that abhorrence which his name excites among many who have never looked into his writings. Hobbes was inconsistent, but he seems never to have seen this, and to have been thoroughly sincere in his doctrines. Though the tendency of his writings is objectionable, there is no appearance of the slightest design of impairing the credit of Christianity, and he evidently thought that the publication of his doctrines would promote the political interests of his country and the world. Notwithstanding his power in exciting philosophical reflection, we are not now in need of his aid, as we possess abundance of literature better adapted to every purpose of philosophy; and we can only turn our attention occasionally to his writings as objects of curiosity, forming a remarkable epoch in the history of human opinions. See Leland's *View of Deistical Writers;* Mosheim's *Ecclesiastical History;* Aubrey's *Letters and Anecdotes;* and Hobbes's *Works.* (*H. D.*)

HODEIDA is a sea-port town of Arabia, situated on the Red Sea. Although the harbour is larger than that of Loheia, yet it will admit only small vessels. The town is large, and is composed principally of huts built in the ordinary style. The mansion of the Dolah, or governor, the mosques, the custom-house, and the houses of the principal merchants, are built of stone. There is a small castle near the sea, but it is not capable of much defence. At the distance of a mile and a half from Hodeida is a well of excellent water, from which the town is supplied, the water nearer the town being very bad. Hodeida is the sea-port of Beetlefackie, a town in the interior, about 30 miles from the coast, and only about half a day's journey from the hills where the coffee grows.

The Dolah of Hodeida is accountable only to the Imam; but his jurisdiction is confined to the city. His revenues consist partly of the duties upon exported coffee. All the mercantile transactions at Hodeida are carried on in Spanish dollars and cavears; 40 cavears making one Spanish dollar. The cavear is an imaginary coin. All foreign coins pass current here. The coffee from Beetlefackie, which is intended for India, Muscat, or Europe, is sent by land to Mocha; but that which is intended for Jidda, is shipped at Hodeida. East Long. 42° 59′, and North Lat. 14° 49′, according to Lord Valentia's chart. See Niebuhr's *Travels through Arabia*, sect. ix. chap. 2.; and Milburne's *Oriental Commerce*, vol. i. p. 95, 96.

HOEING. See Agriculture.

HOGARTH, William, the celebrated painter, was the grandson of a yeoman, who possessed a small tenement in the vale of Bampton, near Kendal in Westmoreland. He had three sons. The eldest succeeded his father in his little freehold; the second settled at Troutbeck, near Kendal, and was remarkable for a talent at provincial poetry;* the

* We trust that it will not be indulging in diffuse or impertinent anecdote, to subjoin a few particulars respecting this poetical uncle of the great Hogarth, whom we find denominated the Mountain Theocritus of his native place by Mr Walker, the lecturer on natural philosophy, who came from the same part of the country. The songs and quibbles, he says, of old Hogarth, had often delighted him in his youthful years. "Those simple strains," he adds, "were composed while he held the plough, or was leading his fuel from the hills."—Who does not recall Burns to his recollection in perusing this circumstance?—"He was," continues Mr Walker, "as critical an observer of nature as his nephew, for the narrow field he had to view her in. Not an incident or an absurdity in the neighbourhood escaped him. If any one was hardy enough to break through any decorum of old and established repute,—if any one attempted to over-reach his neighbour, or cast a leering eye at his wife, he was sure to hear himself sung over the whole parish, nay, to the very boundaries of the Westmoreland dialect; so that his songs were said to have had a greater effect on the manners of his neighbourhood, than even the sermons of the parson himself. But his poetical

third son, who was the father of the painter, after having kept a school in the country, came to London, and pursued the same occupation in Ship Court, in the Old Bailey. William Hogarth was born in the parish of St Bartholomew in 1698, and seems to have received only the usual education of a mechanic. He was bound apprentice to Ellis Gamble, a silversmith in Cranbourn Court, Leicester-fields; and was to learn in that profession only the branch of engraving arms and cyphers on metal. Before his apprenticeship had expired, his genius for drawing began to point to the comic path which it afterwards pursued. Having one day rambled to Highgate with some companions, he witnessed a quarrel in a public-house, in which one of the disputants received a blow with a quart pot, that made the blood stream down his face. Such a subject, one would think, was little calculated for gay effect; but humour is not an over-delicate faculty, and the distorted features of the wounded sufferer, it seems, so much attracted the fancy of young Hogarth, that he sketched his portrait on the spot, with the surrounding figures, in ludicrous caricature. His apprenticeship was no sooner expired, than he entered into the academy of St Martin's Lane, and studied drawing from the life, in which he never attained to great excellence. It was character, the passions, the soul, that his genius was given him to copy. In colouring, he proved no great master; his forte lay in expression, not in tints and chiaro-scuro. It is not exactly known how long he continued in obscurity, but the first piece in which he distinguished himself as a painter, is a representation of Wanstead Assembly. In this are introduced portraits of the first Earl Tylney, his lady, their children, tenants, &c. The colouring of this is said to be better than that of some of his later and more highly finished pieces.

From the date of the earliest plate that can be ascertained to be the work of Hogarth, it may be presumed, that he began business on his own account at least as early as the year 1720. His first employment seems to have been the engraving of arms and shop bills; the next to design and furnish plates for booksellers.* Among these, were designs for Hudibras, with Butler's head. His Hudibras (says Horace Walpole) was the first of his works that marked him as a man above the common; yet what made him then noticed now surprises us, to find so little humour in an undertaking so congenial to his talents.

The success of his plates was sufficient to bring him business as a portrait painter; but it was not permanent, or attended with much reputation. The author of the volume of anecdotes respecting him, affirms with confidence, that though not a portrait painter, who could gratify the self-love of his employers, he drew individual likenesses in his best pieces. One of his most striking scenes of this sort, was the examination of the committee of the House of Commons into the cruelties exercised on the prisoners of the Fleet to extort money from them. On the table of the committee are the instruments of torture. A prisoner in rags, half starved, appears before them, with a good countenance, that adds to the interest. On the other side is the confronted and atrocious goaler, with villainy, terror, and the eagerness to tell a lie, depicted in his features, and expressed in his gesture. This was Bambridge, the warden of the fleet, who, with Huggins his predecessor, were both declared guilty of extortion and cruelty. In 1730 Hogarth made a clandestine marriage with the daughter of Sir James Thornhill, sergeant painter, and history painter, to George I. Hogarth was at this time called in the Craftsman an ingenious designer and engraver; but his father-in-law regarded him as so unworthy of his daughter, and was so much offended by the match being a stolen one, that he was not easily reconciled to it. About the same period our painter began his celebrated Harlot's Progress, some scenes of which were purposely put in the way of Sir James Thornhill, to bespeak his favour. Sir James remarked, that the man who could produce such works could maintain a wife without a portion; but he afterwards relented, and the young pair took up their abode in his house.

By the appearance of his Harlot's Progress, his fame was completely established, and his finances raised, by the rapid sale of the plates that were struck from the pictures. He might be said in this production to create a new species of painting,—the moral comic; and in the furniture, dresses, and details of the scenes, to give a history of the manners of the age. The Rake's Progress, which appeared in 1735, though, in the opinion of many, superior in merit, had not so much success from want of novelty. In

talents were not confined to the incidents of his village. I myself bave had the honour to bear a part in one of his plays, (I say one, because many are extant in MS. in the mountains of Westmoreland at this hour.) This play was called *The Destruction of Troy.* It was written in metre, much in the manner of Lopez de Vega, or the ancient French drama. The unities were not too strictly observed, for the siege of ten years was all represented. Every hero was in the piece, so that the dramatis personæ consisted of every lad of genius in the whole parish. The wooden horse—Hector dragged by the heels—the fury of Diomede—the flight of Æneas—and the burning of the city—were all represented. I remember not what fairies had to do in all this; but, as I happened to be about three feet high at the time of this still-talked of exhibition, I personated one of these tiny beings. The stage was a fabrication of boards placed about six feet high on strong posts; the green-room was partitioned off with the same materials; its ceiling was the azure canopy of heaven; and the boxes, pit, and galleries, were laid into one by the great Author of Nature, for they were the green slope of a fine hill Despise not, reader, this bumble state of the provincial drama. Let me tell you, there were more spectators for three days together than your three theatres in London would hold; and let me add, still more to your confusion, that you never saw an audience half so well pleased. The exhibition was begun with a grand procession from the village to a great stone, dropped by the devil, about a quarter of a mile off, when he tried in vain to erect a bridge across Windermere; so the people, unlike the rest of the world, have remained a very good sort of people ever since. I say the procession was begun by the minstrels of five parishes, and were followed by a yeoman on bull-back. This adept had so far civilized his bull, that he would suffer the yeoman to mount bis back, and even to play the fiddle there."——After detailing an accident that befel the yeoman, from his bull running away with him, the narrator proceeds:—"This accident rather inflamed than depressed the good-humour arising from the procession; and the Clown, or Jack-pudding of the piece, availed himself so well of the incident, that the lungs and ribs of the spectators were in manifest danger. This character was the most important personage in the whole play. He was a compound of Harlequin and Merry-Andrew, or rather the arch fool of our ancient kings. . . . . . . The play was opened by this character with a song, which answered the double purpose of a play-bill and a prologue: for his ditty gave the audience a foretaste of the rueful incidents they were about to behold, and it called out the actors, one by one, to make the spectators acquainted with their names and characters, till the whole dramatis personæ made one great circle on the stage. The audience being thus become acquainted with the actors, the play opened with Paris running away with Helen, and Menelaus scampering after them. Then followed the death of Patroclus, the rage of Achilles, the persuasions of Ulysses, &c. &c. and the whole interlarded with apt songs, all the production of ald (old) Hogarth. The bard, however, had been dead some years; and, I believe, this Fête was a jubilee to his memory. But let it not detract from the merit of Mr Garrick to say, that his at Stratford was but a copy of one forty years ago on the banks of Windermere. Was it any improvement, think you, to introduce several bulls instead of one? But I love not comparisons; and so conclude, yours, &c. ADAM WALKER."—*From Anecdotes of Hogarth.*

* Thirteen folio prints, with his name to each, appeared in Aubrey de la Mortraye's Travels, 1723. Seven smaller prints for Apuleius's Golden Ass, 1724. Fifteen head pieces to Beaver's Military Punishments of the Ancients; and five Frontispieces for the translation of Cassandra, in five vols. 1725 Seventeen cuts for Hudibras, 1726. Two for Perseus and Andromeda, 1730. Two for Milton, the date uncertain; and a variety of others between 1726 and 1733.

the following year, ambitious of distinguishing himself as a painter of history, he finished the Scripture scene of the Pool of Bethesda, and of the Good Samaritan; but the burlesque turn of his mind mixed itself with all subjects, and here with disadvantage. Nor was he more successful in his picture of Danaë, where the old nurse tries the gold by ringing it with her teeth. His fame was however now so high, that Swift complimented him in the Legion Club, and Fielding in his preface to Joseph Andrews. Theophilus Cibber had also brought his Rake's Progress on the stage, in the shape of a pantomime.

His printed proposals, dated January 25, ascertain his Company of Strolling Players, and his Marriage a la Mode, to have been then ready for sale. He had also projected a Happy Marriage, by way of a counterpart to his Marriage a la Mode. The time supposed was immediately after the return of the parties from church. The scene lay in the hall of an antiquated country mansion. On one side the married couple were represented sitting. Behind them was a group of their young friends of both sexes, in the act of breaking bride-cake over their heads. In front appeared the father of the young lady grasping a bumper, and drinking, with a seeming roar of exultation, to the future happiness of her and her husband. By his side was a table covered with refreshments; jollity rather than politeness, was the designation of his character. Under the screen of the hall, several rustic musicians in grotesque attitudes, together with servants, tenants, &c. were arranged. Before the dripping-pan stood a well-fed divine, with his gown and cassock, with his watch in his hand, giving directions to a cook dressed all in white, who was basting a haunch of venison. Among the faces of the principal figures, none but that of the young lady was completely finished. Hogarth had been often reproached for his inability to give grace and dignity to his heroines. The bride was meant to vindicate his pencil from this imputation. The effort, however, was unsuccessful. The girl was pretty, but her features were uneducated. She might have attracted notice as a chambermaid, but would have failed to extort applause as a woman of fashion. The parson and his culinary associates were more laboured than any other parts of the picture. The painter sat down with a resolution to delineate beauty improved by art, but seems, as usual, to have deviated into meanness, or could not help neglecting his original purpose to luxuriate in more congenial ideas. He found himself, in short, out of his element in the parlour, and therefore hastened in quest of ease and amusement to the kitchen fire.

Soon after the peace of Aix-la-Chapelle, he went over to France, and was taken into custody while he was drawing the gate of that town; a circumstance which he has recorded in his picture, entitled *O the Roast Beef of Old England*, published in 1749. He was actually carried before the governor as a spy; and after a very strict examination, committed a prisoner to Grandsire his landlord, on his promising that Hogarth should not go out of the house till he was to embark for England. Previous to this commitment, he had behaved with a sturdiness and sauciness which he thought became an Englishman, but which betray the extreme grossness of his manners. In the streets he was often clamorously rude. A tattered bag, or a pair of silk stockings with holes in them, drew a torrent of imprudent language from him, and which there were Scotch and Irish emigrants on the spot who could interpret to the French. But his pleasantry was extinguished by what happened when he was drawing the gates of Calais; for though the innocence of his design was rendered perfectly apparent on the testimony of other sketches he had about him, which were by no means such as could serve the purpose of an engineer, he was told by the commandant, that had not the peace been actually signed, he should have been obliged to have hung him up immediately on the ramparts. Two guards were then provided to convey him on shipboard; nor did they quit him till he was three miles from the shore. They then spun him round like a top on the deck, and told him he was at liberty to proceed on his voyage without farther molestation or attendance. The slightest allusion to this ludicrous affair used to be offensive to our painter.

In 1753, he appeared in the character of an author, and published a quarto volume, entitled *The Analysis of Beauty*, written with a view of fixing the fluctuating ideas of taste. His intention was to shew that a curve is the line of beauty, and that round swelling figures are most pleasing to the eye. He received assistance in this work from Dr Benjamin Hoadley the physician, and the Rev. Mr Townley corrected the preface. The family of Hogarth rejoiced when the last sheet of his Analysis was printed off, as the frequent disputes he had with his coadjutors in the course of the work, did not much harmonize his disposition. If beauty really did consist in any particular kind of lines, there were few painters less likely to discover them than Hogarth, and he was no metaphysician; but the refutation of an exploded theory would be now superfluous.

About 1757, his brother-in-law, Mr Thornhill, resigned the place of King's sergeant-painter, in favour of Hogarth, who soon after made an experiment in painting that involved him in some confusion. The collection of pictures of Sir Luke Schaub, was sold in 1758, by public auction; and the celebrated painting of Sigismunda, said to be the work of Corregio, (Mr Walpole thought that it was by Furino,) excited his emulation. From a contempt of the ignorant virtuosi of the age, many of whom he had seen bubbled by vile copies, as well as from having never studied the great Italian masters, he persuaded himself that the praises bestowed on their glorious works were only the effects of prejudice. He went farther; he determined to rival the ancients, and unfortunately chose the subject we have mentioned. His Sigismunda is described by Walpole as the representation of a maudlin strumpet, just turned out of keeping, and with eyes red with rage and usquebaugh. Her fingers blood-red by her lover's heart, (the blood was afterwards expunged from her fingers,) that lay before her like that of a sheep for dinner. None of the sober grief; no dignity of suppressed anguish; no settled meditation of the fate she meant to meet; no amorous warmth turned holy by despair; in short, all was wanting that should have been there; all was there that such a story would have banished from a mind capable of conceiving such complicated woe,—woe so sternly felt, and yet so tenderly. Hogarth's performance was more ridiculous than any thing he had ever ridiculed. He set the price of 400*l*. on it, and had it returned on his hands by the person for whom it was painted. This unfortunate picture, which was the source of so much vexation to Hogarth, at least made a versifier of him. He addressed an epistle to a friend, occasioned by Sir Richard Grosvenor (now lord) returning the picture on the artist's hands. The verses are splenetic and conceited, without a particle of wit or humour.

The last memorable event in his life, was his quarrel with Mr. Wilkes. His connection with the court probably induced him to quit the line of party neutrality which he had hitherto observed, and to engage against Mr Wilkes and his friends in a print, September, 1762, entitled *The Times*. He was attacked, in return, in a number of the *North Briton*, which produced his caricature of Wilkes. At an early period of his career, Hogarth had ventured to assail Pope himself in the blaze of his poetical reputation,* and from his exasperation he escaped, either by his obscurity, or by the prudence of the poet. But he was now destined to feel the lash of a writer, inferior indeed in fame, but equal in the talents of vituperation. Churchill avenged the caricature of his patron Wilkes, by his *Epistle to Hogarth*, not, indeed, the brightest of his works, and in which the severest of his strokes fell upon his age. Hogarth retaliated by caricaturing Churchill under the form of a canonical bear, with a club and a pot of porter. Never, as Walpole truly remarks, did two angry men, of their abilities, throw mud with less dexterity.

It deserves to be noticed, that, amidst the bitterest invectives on Hogarth, his enemy, Churchill, conceded a degree of merit to him, with which his warmest admirers may be contented, and a description of his genius, to which they would find it difficult to add a material circumstance.

In walks of humour, in that cast of style,
Which, probing to the quick, yet makes us smile;
In comedy, his natural road to fame,
Nor let me call it by a meaner name,
Where a beginning, middle, and an end,
Are aptly join'd; where parts on parts depend,
Each made for each, as bodies for their soul,
So as to form one true and perfect whole,
Where a plain story to the eye is told,
Which we conceive the moment we behold;
Hogarth unrivall'd stands, and shall engage
Unrivall'd praise to the most distant age.

Hogarth having been said to be in his dotage when he produced his print of the bear, it should seem, was provoked to make the following additions to this print, in order to give a farther specimen of his still existing genius. In the form of a framed picture on the painter's pallet, he has represented an Egyptian pyramid, on the side of which is a Cheshire cheese, and round it 3000l. per annum, and at the foot a Roman veteran in a reclining posture, designed as an allusion to Mr Pitt's resignation. The cheese is meant to allude to a former speech of Mr Pitt's, in which he said that he would rather subsist a week on a Cheshire cheese and a shoulder of mutton, than submit to the enemies of his country. But to ridicule this character still more, he is, as he lies down, firing a piece of ordnance at the standard of Britain, on which is a dove, with an olive branch, the emblem of peace. On one side of the pyramid is the city of London represented by the figure of one of the Guildhall giants going to crown the reclining hero. On the other side is the King of Prussia, in the character of one of the Cæsars, but smoking his pipe. In the centre stands Hogarth himself, whipping a dancing bear, (Churchill,) which he holds in a string. At the side of the bear is a monkey, designed by Mr Wilkes. Between the legs of the little animal is a mop-stick, on which he seems to ride like a child on a hobby-horse. At the top of the mop-stick is the cap of liberty. The monkey is undergoing the same discipline as the bear. Behind the monkey is the figure of a man, but with no lineaments of face, and playing on a fiddle. This was designed for Earl Temple, in allusion to the inexpressiveness of his countenance.

Amidst these disgraceful hostilities, Hogarth was visibly declining in his health. In 1762, he complained of an inward pain, which proved to be an aneurism, and became incurable. The last year of his life was employed in retouching his plates, with the assistance of several engravers, whom he took with him to Chiswick. On the 25th of October, 1764, he was conveyed from thence to his house in Leicester Fields, in a very weak condition, yet remarkably cheerful; and receiving an agreeable letter from the celebrated Dr Franklin, he drew up a rough draught of an answer to it. In the night time, however, he was seized with a vomiting, probably owing to a circumstance of which he had boasted before going to bed, viz. that he had eat a pound of beef steaks to his dinner, and expired about two hours after, aged 67. His corpse was interred in the Church-yard of Chiswick, on a monument which bears a simple inscription on one side, and on the other emblematic ornaments, with some verses by Garrick.

In his private character this celebrated man is reputed to have been hospitable and liberal, as well as accurately just in his dealings, but his manners were coarse and vulgar, and his powers of delighting seem to have been restrained to his pencil. To be a member of clubs of illiterate men was the utmost of his social ambition, and even in those assemblies he was oftener sent to Coventry than any other member. The slightest contradiction is said to have transported him to rage. His genius as a comic painter is of that strong description which breaks down the partition between connoisseurship and the popular taste in the enjoyment of it. It is merit, which his satirist yet ablest panegyrist so well expressed, "which we conceive the moment we behold." The critic Du Bos often complained that no history painter of his time went through a series of actions. What Du Bos wished to see done, Hogarth performed, though probably without knowing that he was so obligingly complying with the critic's request. In his Harlot's Progress he launches out his young adventurer, a simple girl upon the town, and conducts her through all the vicissitudes of wretchedness to a premature death. This was painting to the understanding and to the heart. None had before made the comic pencil subservient to instruction; nor was the success of this painter confined to his persons. One of his excellencies consisted in what may be termed the furniture of his pieces; for as in sublime historical representations the fewer trivial circumstances are permitted to divide the spectator's attention, the greater is the force of the principal figures; so in scenes of familiar life, a judicious variety of little incidents contributes an air of versimilitude to the whole. The rake's levee room, (Walpole observes,) the nobleman's dining room, the apartments of the husband and wife in marriage *à la mode*, the alderman's parlour, the bedchamber, and many others, are the history of the manners of the age.*

For a scientific view of the works of this great artist, we must refer the reader to Walpole's Anecdotes of Painters, which we have already quoted.—A complete list of his prints, at least the most complete that has been made out, will be found in the Biographical Anecdotes, by Nichols. Walpole has made one remark upon them, in his eulogy of Hogarth, against the truth of which his works bear ocular demonstration, viz. that his delicacy is

* In a plate, entitled *The Man of Taste*, 1732, (for a poem of Welsted, we believe,) containing a view of the gate of Burlington-house, with Pope whitewashing it, and bespattering the Duke of Chandos's coach, as well as in a ludicrous picture on the subject of the South Sea bubble.

† Among the small articles of furniture in the scenes of Hogarth, (says the compiler of the anecdotes of his life,) a few objects may speedily become unintelligible, because their archetypes being out of use, and of perishable natures, can no longer be found. Such is the *dare for larks*, a circular board, with pieces of looking-glass inserted in it, hung up over the chimney-piece of the distressed poet; and the Jew's cake, (a dry tasteless biscuit, perforated with many holes, and formerly given away in great quantities at the feast of the passover,) generally used only as a fly-trap, and hung up as such against the wall in the sixth plate of the Harlot's Progress.

superior to that of the Dutch painters, or rather that his indelicacy is less. The illustration of this would be a task more easy than agreeable. Mr Gilpin, in his Essay on Prints, observes, that in design Hogarth was seldom at a loss. His invention was fertile, and his judgment accurate. An improper incident is rarely introduced. In composition, he continues, we see little in him to admire; in many of his prints, the deficiency is so great, as to imply a want of all principle, which makes us ready to believe that when we do meet with a beautiful group, it is the effect of chance. Of the distribution of light, according to the same writer, he had as little knowledge as of composition. Neither was Hogarth a master of drawing. But of his expression, in which the force of his genius lay, we cannot speak in too high terms; in every mode of it he was truly excellent. The passions he thoroughly understood, and all the effects which they produce in every part of the human frame; he had the happy art also of conveying his ideas with the same precision with which he conceived them. (*n*)

HOLBEIN, John, or Hans, an eminent painter, was born at Basle, in Switzerland, in the year 1498. He was instructed in the art by his father John Holbein, whom he very soon surpassed. Holbein was the particular friend of the celebrated Erasmus. At his request he visited London, where he was patronised by Sir Thomas More, to whom Erasmus had introduced him. Sir Thomas employed him in painting the whole of his family, and several of his relations and friends, and he allowed him an apartment in his own house, where he continued for three years. When King Henry VIII. saw these performances, he was so much struck with the talent which they displayed, that he took Holbein into his service, and honoured him with his patronage and kindness during the rest of his life.

It is a singular circumstance, that Holbein always painted with his left hand. He succeeded equally in oil, water colours, and distemper. After he arrived in England, he learned the art of miniature painting from Lucas Cornelii, and carried it to a very high degree of perfection.

In the Florentine collection, are the portraits of Martin Luther, Sir Thomas More, Richard Southwell, and of Holbein, all painted by our author. The "Sacrifice of Abraham," which has been much admired, is in the cabinet of the King of France, along with several portraits executed by Holbein.

In the library of the university of Basle are several of Holbein's works in the highest preservation. A few are preserved, which he painted before he was 15 years old; one of which he drew upon a sign for a writing-master. The portraits of himself, his wife, and children, in the same group, are much esteemed. The other pictures of Holbein in this collection are, the Passion of our Saviour, in eight compartments; the Institution of the Supper; the Body of our Saviour after the Crucifixion; a Lucretia; a Venus; a Cupid; and portraits of Erasmus and Ammerbach. Erasmus is represented as writing his Commentary upon Matthew. In the same library are preserved a copy of Erasmus's *Eloge de la Folie*, which he had presented to Holbein, who ornamented the margin of it with very interesting sketches, done with the pen. An edition of this work was published at Basle, in 1676, by Charles Patin, who got the original sketches copied by Stettler of Berne, and engraved by Merian. A new edition of this work, in Latin, French, and German, with fac-similes of the original designs engraven on wood, was published by M. Haas in 1780. The paintings of Holbein on the organ of the cathedral are still to be seen.

The Dance of Death, on the walls of the cemetery of the Dominicans at Basle, was not painted, as has often been said, by Holbein, but by John Klauber, at the desire of the council, when the plague ravaged that city. These walls were pulled down in 1805. The paintings had been restored in 1558, 1616, 1658, and 1703. Since the year 1792, they have been almost entirely effaced. From these paintings it is probable that Holbein took the idea of composing the famous drawings of the Dance of Death; in which he has shewn so much judgment and imagination, that even Rubens condescended to study and copy them. It consisted of 44 designs, done with the pen, and slightly shaded with Indian ink. These designs were engraved by Haller, and more recently by M. de Mechel, a celebrated artist of Basle. The originals were sold, along with the famous collection of Crozat at Paris, to M. Fleichman of Strasburg. In the reign of the Emperor Joseph II. the Prince Gallitzin, the Russian ambassador at Vienna, purchased them, and carried them to St Petersburg. Holbein died in the year 1554, in the 56th year of his age. See Coxe's *Travels in Switzerland*, vol. i. p. 162.

HOLDEN'S Temperament of the Musical Scale. In 1770, Mr John Holden, in a work on music, in long quarto, recommended a system of tuning, in which each of the fifths, except that on ♯G, should be flattened $\frac{1}{5}$th of a major comma; producing a perfect or untempered major seventh; and a major third and major fifth, alike tempered by the $\frac{1}{5}$th of a major comma, but in contrary directions, as Mr Farey has shewn in the *Philosophical Magazine*, vol. xxxvi. p. 46; and Mr Liston in his *Essay on Perfect Intonation*, p. 22.

The latter gentleman, in p. 23. describes this system as being "nearly what *is in common use*;" and in p. 142, gives it the preference over the scale which Mr Hawkes at last adopted, (viz. V—$\frac{1}{6}$C, see his Temperament); on which account, we shall here present the musical student with a table of the beats of each of the 72 concords in Mr Holden's system, calculated on purpose for our work, viz.

| Notes. | Σ Value of the Notes. | + f | + m | Vibrations in 1″ of time. | *Flat*, of 3d on | *Sharp*, of IIId on | *Sharp*, of 4th on | *Flat*, of Vth on | *Flat*, of 6th on | *Sharp*, of VIth on |
| | | | | | Beats in 1″ of time. | | | | | |

In column 2, the notes are set down in the nearest regular interval in Farey's notation: col. 3. is adapted to the octave above tenor-cliff C; and the beats are expressed in the six following columns, all of them beating *flat* or beating *sharp*, as expressed at the bottom of the several columns, except ♭E in col. 6, and ♯G in col. 7, which are the reverse of all the other fourths and fifths in this system: in which only two of the notes differ from those since adopted by Mr William Hawkes. See Hawkes' *Temperament*.

In a subsequent edition of his work, in octavo, entitled "An Essay towards a rational System of Music," Mr Holden, from having, unfortunately, adopted a defective rule for calculating the *Grave* Harmonics of a consonance, (see that Article), conceived, that he had legitimately introduced the prime number 7 into musical ratios; and thereupon, in the 2d part of his book, grounds a great many unfounded and false rules and conclusions, regarding harmonics: in particular, he gives an ascending and a descending scale, which, when combined, contains 24 notes within the octave, eleven of which involve the number 7 in their numerical ratios. (*g*)

# HOLLAND.

Holland, one of the provinces of the kingdom of the Netherlands, and, before the formation of that kingdom, the most considerable of the united provinces of the Netherlands, is bounded on the west by the German Ocean, or North Sea; on the north by the Zuyder Zee, which separates it from the province of Friesland; on the east, by the same sea, which separates it from the province of Overyssel, and by the province of Utrecht, and part of Guelderland; and on the south by the province of Zealand, and part of Brabant. It is situated between the latitude of 51° 40′ and 53° 10′ north, and the longitude of 3° 56′ and 5° 30′ east of London. Its greatest extent, from south to north, including the isle of Texel, is about 90 miles, and from east to west not above 25 miles in some places, and above 40 in others, it being of a very irregular figure, and extremely narrow towards its northern extremity. According to the calculation taken in the year 1554, there were upwards of 300,000 morgens of land in this province, each morgen being about two English acres. The states of Holland and Zealand, in a remonstrance made soon after this year to the Earl of Leicester, contended, that these two provinces, with all their heath, downs, and grounds delved out, could make in all but about 500,000 morgens; and De Witt, in his work on the true interests of Holland, calculates that there cannot possibly be more than 400,000 morgens of land in this province, down and heath not included.

This province is divided into South Holland, commonly called Ug Holland; and North Holland, generally called West Friesland, and sometimes Waterland; there are also subdivisions, the principal of which will be afterwards noticed. Both South Holland and North Holland contain a great many considerable cities, besides a vast number of large and beautiful villages. In South Holland the principal places are Amsterdam, Rotterdam, the Hague, Leyden, Haerlem, Dordrecht or Dort, Delft, the Briel, Gorcum, Gouda, &c. Rhineland is a subdivision or district in South Holland, the capital of which is Leyden: it contains within its jurisdiction 45 large boroughs and villages. This subdivision is bounded on the west by the coast of Holland; on the east by part of the province of Utrecht, and by Amstelland; on the north by part of the river Y, along the course of the dyke that goes from Haerlem to Amsterdam, and by the shallows and washes as far as Beverwic; and on the south, by a line drawn from Montfort through Oudewater and Gouda to the Hague: it has its name of Rhineland from the middle branch of the Rhine running through it. All the inhabitants of this district are obliged by law, agreed to among themselves, to provide for the maintenance and reparation of the dykes, sluices, and canals within the district; and they have a council which meets every Saturday at the Rhineland House, in Leyden. This council is composed of the Dyke-graaf, and seven assistants, called Heemraden. There are several islands belonging to South Holland: The island of Voornlees, between the mouths of the river Maese; Briel is the capital: This island, along with the small adjoining islands of Goree, and Overslackee, form the territory called Voornland, which was anciently part of Zealand. The isle of Ruggonhill, to the east of that of Voorn, of which Williamstadt is the principal town, together with the isle of Finard, formerly belonged to Brabant.

North Holland is divided from South Holland by the river Y. The principal towns in it are Saardam, Edam, Monikendam, Alcmaer, and Hoorn. Across the mouth of the Zuyder Zee lies a row of islands, belonging to North Holland. The Texel island is separated from the North Cape of North Holland by a very narrow channel; it is about eight miles long and five broad; it is defended from the sea by sand hills and strong banks; there are several villages in it, and a large town on the east side, called Burgh, which enjoys the privileges of a city. As this island lies at the mouth of the Zuyder Zee, and commands the only passage to Amsterdam, the States have built a strong fortress on it, in which a considerable garrison is always kept. The island of Vlieland lies towards the north-east of the Texel; it is about nine miles long, and two broad; it has only two small villages; and is chiefly remarkable for the great quantity of muscles found on it. The island of Schelling lies to the north-east of Vlieland; and is about 10 miles long, and three broad; there are five villages on it. These islands, together with several large sand-banks, break the rage of the ocean, and form two good harbours, or rather roadsteds, at the Texel and the Vlie; the first being a noted station for ships bound to the south, and the other for those bound to the north. The Wierengen, thus called from the great quantity of sea-weed, named in Dutch, as in Scotch, *Wier*, is a number of little islands, which lie more to the south, on the coast of North Holland; the principal of them is five miles long, and two broad, and contains several villages.

The name of Holland, (the hollow land,) sufficiently indicates the nature of the country. The level of a great part of it is, indeed, below the level of the sea, which is kept out only by means of dykes, or natural sand banks. In many parts, the dyke, or mound, is 30 feet above the adjoining land; the width at top is enough to permit the passage of two carriages; and there is a sort of imperfect road along it. In its descent, the breadth increases so much, that it is not very difficult to walk down either side. On the land side, it is strengthened by stone and timber, and covered by earth and grass; towards the sea, somewhat above, and considerably below water-wark, a strong matting of flags prevents the surge from carrying away the surface of the mound. This kind of defence appears to have been discovered in the 17th century; for Sir William Temple, in his observations on the Netherlands, expressly says, it was lately found out. This matting is held to the shore by bandages of twisted flags running horizontally, at the distance of three or four yards from each other, and staked to the ground by strong wooden pins. As this matting is worn by every tide, a survey of it is frequently made. Farther in the sea, it is held down by stones. Above, there are posts at every 40 yards, which are numbered, that the spot may be exactly described where repairs are necessary. The impost, for the maintenance of these banks, amounts to nearly as much as the land-tax. Sir William Temple asserts, that these dykes employ annually more men than all the corn of the province of Holland could maintain. In the time of De Witt, the making of one rood's length of sea-dyke sometimes cost 600 guilders. Besides these sea-dykes, there are other dykes to keep out the waters of the rivers. In the time of De Witt, the annual charges of the district of Rhineland, which contains about 8000 morgens, and has not much communication with the sea, nor with running but only with standing waters, paid as acredge money and inland charges, at least two guilders for every acre; besides for drawing out of the rain water by mills each acre 30 stivers, and towards foot paths, highways, and ditches, at least 20 stivers more. The banks or dykes near Medenblick, in North Holland, near the Zuyder Zee, are stronger, broader, and higher, than any others in the country; for there being nothing to break the violence of the sea from the islands of Schelling and Vlieland to this shore, the water beats most furiously upon it when the northerly winds blow, and at spring-tides the sea rises sometimes as high as the dykes, and would even overflow and break them down, did not the inhabitants stop its fury by laying sails over the dykes, which preserve them in a tempest. Whenever the water of the sea, or the rivers, breaks over upon the lands, they are drained by means of wind-mills, of which there are immense numbers for this purpose. From what has been already said, it may well be imagined, that the general face of the country is that of a large marsh that has been drained, the canals, and even the sea, looking pale, and even discoloured by mud; yet the eye is not unfrequently relieved and delighted by the groves, gardens, and meadows, while the great rivers, and the immense number of canals in this province, leading not only to every great town, but to every village, and almost to every farm-house, present an infinite number of vessels everywhere coursing up and down upon them.

The principal rivers in Holland are, the Rhine. When we come to treat of the progressive geography of this province, the changes in the course of the Rhine, so far as they are connected with it, will be mentioned; at present, we shall confine ourselves to its present state in Holland. According to some geographers, the northern mouth of this river must be sought in the Leck, which joins the estuary of the Meuse, between Dort and Rotterdam; according to others, it runs through Leyden, where it divides itself into two canals, one of which runs into the lake of Haerlem, and the other loses itself, four miles beyond Leyden, in the sand hills between Catwyk on the Rhine, and Catwyk on the sea, where was anciently the mouth by which it emptied itself into the ocean. The Leck, if it be not the ancient Rhine, must be regarded as another river in Holland; its course has been already mentioned. There is another small branch of the Rhine called the Vaert, or Vecht, which falls into the Zuyder Zee at Muyden, about eight miles to the east of Amsterdam. The little Yssel falls into the Maes, a short way to the east of Rotterdam. The Maes, passing before Gorcum, runs to Dort, where it divides itself into two large branches, forming an island called Ysselmonde. The most northern branch runs to Rotterdam; it is called the New Maes, to distinguish it from the southern branch, which is called the Old Maes. They reunite a little before they reach Vlardingen, and enter the ocean, by a wide mouth, a little below Briel. The Amstel is not properly a river, but rather a collection of waters from the Drecht, the Miert, and other rivulets, the waters of which are swelled by their communication with lakes and rivers, by means of canals. The Y, called by some a river, is more properly a branch of the Zuyder Zee, from which it begins, at a sand bank called the Pampus. Its channel here is half a mile broad, which breadth it continues to Amsterdam, but grows soon afterwards twice as broad. It receives the waters from the lake of Haerlem by a large canal, called the Sparen, and from several lakes in North Holland. It afterwards passes northwards to Beverwyk, without discharging itself again into the sea.

From the town of Haerlem, the great lake called the Haerlem Meer, or Sea of Haerlem, derives its name. It is situated between Haerlem, Amsterdam, and Leyden; and is formed by the waters of several rivulets, and of the sea, with which, as has just been noticed, it has a communication by means of the Y, which enters it by a sluice, strongly built with brick-work. From its communication with the sea, the waters of the Meer are brackish. There are canals from its several gulfs to the cities of Amsterdam, Leyden, and Haerlem. On the east side, there is a gulf or branch called the New Meer, from which a canal leads to the suburbs of Amsterdam. Here there is a dyke, over which loaded boats are carried, by means of a wheel and rollers, into another canal. On the north of the lake there is another gulf, where there is a sluice, which opens and shuts itself by the weight of the water. This is the sluice by which the lake communicates with the Y. In one place, the neck of land which separates the Haerlem Meer and the Y is so narrow, that a canal cannot be drawn through it. Both these waters have gained considerably on their respective shores, and if united would be irresistible. At the narrowest part, the neck of land consists of pile-work and masonry to the thickness of about 40 feet. On the south and south-west, Haerlem Meer communicates with several small branches of the Rhine, one of which comes from Leyden. The Haerlem lake is about 12 miles long, and nine broad; and as ground is very dear and valuable in Holland, it has often been proposed to drain it: but the draining of it would probably be productive of great mischief, for it receives the waters when the violent north winds drive them from the German Ocean into the Zuyder Zee and the Y; whereas if, by the draining of the lake, they were confined within the banks of the Y, the city of Amsterdam would be in great danger of being overflowed. Besides this, the lake of Haerlem affords a vast quantity of fish, and the conveniency of navigation not only to the adjoining villages, but also to Leyden, Haerlem, and Amsterdam. There are some small lakes in North Holland, but none deserving of particular notice.

The climate of Holland is humid, cold, and generally unwholesome; the winters are sharp and very long, the rivers being generally rendered unnavigable by the ice for a considerable length of time. In the spring, which is very short, and by no means agreeable, the sharp cold winds frequently blast the blossoms of the fruit trees. The summers are not unfrequently very hot. The climate is also disagreeable and unwholesome, from sudden and extreme changes of temperature. The east wind generally blows nearly the whole of the winter, and is extremely fierce; but it serves to drive away the fogs, with which this country is dreadfully plagued. The moisture of the air is such, especially about Leyden, that all metals are apt to rust, and even the wood to mould. The climate about Williamstadt is particularly unwholesome, from the extreme flatness and marshiness of the ground; whereas, about Naerden, where the country is high and sandy, the air is by no means bad. The soil of Holland is in general uncommonly rich, being in fact alluvial, and consisting of deep fat loam; in some parts, however, it consists of a barren sand. The soil of North Holland, especially in the drained land called the Bemster, is particularly rich. The country near the village of Schagen is reckoned to possess the richest soil in Europe. Land is sold here at double the rate of any other in Holland, there having been trees upon it, one of which, upwards of a century ago, yielded the owner as much fruit in one year as brought him 10*l.* sterling; and a sheep, bred here, was sold, about the same time, for the same sum.

The progressive geography of Holland is so interesting and important, that we have no doubt our readers will pardon us for dwelling on it pretty fully and minutely. It naturally divides itself into what respects the formation or extension of the Zuyder Zee, the alteration in the course, and the diminution of the size of the Rhine, so far as it is connected with Holland, and the changes which the breaking in, or draining off, of the sea has produced in different parts of this province.

From the name of West Friesland, which is given to North Holland, it is highly probable that part, at least of this division of the province of Holland, was formerly united to East Friesland. How much of it belonged to the Frisia Occidentalis of the ancients is not accurately known: some geographers are of opinion, that only that part to the north-east, in which Hoorn, Enchuyzen, and Medenblic are situated, was the ancient Frisia Occidentalis. From the description of Tacitus, it is evident that, in his time, no other distinction was known but that of greater or lesser Frisons; and that distinction arose entirely from the number of the forces which each could respectively bring into the field. He informs us, that among the Frisons were great lakes, evidently implying that they were of fresh water; and this is made yet plainer by the expression *ambiuntque immensos lacus*, which proves that these lakes were inhabited round by these nations. Hence it is probable that the more inland part of what is now the Zuyder Zee, was one of the lakes mentioned by Tacitus, between which and the Texel and Vlie islands, there lay anciently a large tract of land. This opinion is strengthened by several circumstances. These islands lie still in a contiguous line, and like the broken remains of a continued coast. The sea here, too, is remarkably shallow, and the sands through the whole extent very flat. From the inspection of the accurate maps of the ancient and middle geography of Gaul, by D'Anville, it will be seen that part of the present site of the Zuyder Zee was occupied by a considerable inland lake called Flevo. This lay towards the southern part of the present Zuyder Zee. The question then is, By what means, and at what period, were the northern part of the Zuyder Zee formed, and the communication between this Sea and the ocean opened, or at least rendered so wide as it is at present? From the lake of Flevo ran a river of the same name into the ocean. Formerly the Rhine divided itself into two grand branches at Burginasium, the present Schenck, about five miles north-west of the Colonia Trajana, now an inconsiderable hamlet, called Coln, near Cleves. The southern branch joined the Meuse at the town of Meusa, while the northern passed by Leyden into the ocean. From this branch Drusus formed a canal, bearing his name, which originally joined the Rhine to the Yssel, a river which flowed into the lake Flevo. This canal being neglected, the Rhine joined the Yssel with such force, that their waters increased the lake of Flevo to a great extent, by which means it was carried forward to the ocean by a wide gulf, instead of having a communication with it only by means of the river Flevo. It is probable, also, that the entrance of this river into the ocean was much widened by the force of the waves; for, at present, the violent rage of the waves breaking in towards the mouth of the Zuyder Zee, threatens the parts of North Holland about Medenblick and Enchuysen, braving it over the highest and strongest dykes of the province upon every high tide and storm at north-west. The exact period when the lake Flevo was extended into the Zuyder Zee is not positively known; indeed it is probable that the increase took place at different periods. We are informed by an old Dutch chronicle, published by Vossius, that the increase on the south side, by the breaking in of the inlet to the Texel, took place about the year 1170; others say it was so late as the year 1400. The increase of the lake on its northern side was probably at an earlier period, and also gradual. It certainly was about the year 1400 that the river Y became navigable to Amsterdam by large vessels.

In our account of the progressive geography of the Zuyder Zee, we have partly noticed the changes which have taken place in the course of the Rhine. At the same time that the lake Flevo gained its increase, the northern branch of this river was weakened by the division of its waters; and even the canal of Drusus was afterwards almost obliterated by the deposition of mud in a low country. The Rhine seems to have been farther divided and weakened by a canal cut by Civilis, which, according to Cluverius, is the present Leck; though Pinkerton thinks the deviation of the Rhine into the Leck was the work of natural causes. The same author regards the Leck, which joins the estuary of the Meuse between Dort and Rotterdam, as the northern mouth of the Rhine; which, according to him, the Waal continues to be the southern, both being lost in a comparatively small stream, the Meuse. According to other geographers, what falls into the sea near Catwyk is not the Rhine, but a canal bearing the name of that river. In the sea at low tides, are to be seen, near this village, the foundations of an ancient Roman castle, that commanded the mouths of the Rhine. The Maese, running by Dort and Rotterdam, fell, as it now does, into the sea, at Briel, with a powerful flow of water; but the sands, which are gathered for three or four leagues upon this coast, having obstructed the exit of the river, have caused or increased those inundations, out of which so many islands have been recovered, and of which that part of South Holland is so much composed. Towards the formation of these islands, the Scheldt seems also to have contributed. This river anciently formed a mere Delta, with four or five small islands. At what time the irruptions of this river took place, by which the islands of Zealand, and the most southern of those of Holland, were formed, is not accurately known. Pinkerton is of opinion that they happened at the time that the Godwin sands arose: other authors assign them to violent tempests in the years 860 and 1170. A Zealandic chronicler, quoted by Cluverius, says, that the islands of Zealand were formed by violent tempests in the year 938. It is more probable, however, that these great changes made a slow and gradual progress: none of them being so ancient as the time of Charlemagne, and some of them as recent as the fifteenth century.

Of the most recent changes in the geography of Holland, besides the enlargement of the Zuyder Zee already mentioned, that which took place in the year 1421, to the south-east of Dort, is the most remarkable. Dort is the capital of a bailiwick of the same name. In 1421, this Bailiwick was made an island by a violent tempest, which drove the waters up the Maese and the Mereune with such violence, that they overflowed their banks, and swallowed up a large tract of land, with 70 villages, and 100,000 people; a vast lake between Dort and Brabant was also formed. The name of Dordrecht signifies a ferry,on the river Dort, but that river is now swallowed up by the channel of the Maese. The isle of Rugenhil, on which Willenstedt stands, was covered by the sea for some time; it was recovered so late as the year 1654. Naerden is the capital of a district called Goyland: it lies upon the Zuyder Zee, 13 miles to the east of Amsterdam, and 14 to the north of Utrecht. The old town, which stood more to the north, was swallowed up by the sea. The ruins are still to be seen at low water, 200 perches from the present town.

The drained lands in North Holland deserve particular notice under the head of Progressive Geography; they consist of the Zype, the Beenister, and Purmer, the Wormeer, and Schermeer. The Zype was first drained and encompassed by banks, by William Lord of Schagen, and secured by stronger fences in 1552; but the sea broke them down in 1570. After this it was drained again, and secured by a mole of prodigious height and bulk, proof against all attacks of the sea; and it is now, like all the other drained lands, very fruitful soil. The noise made by the waves which break upon it, sounds like the barking of a pack of hounds, from which circumstance it is called the *Hounds-wood*. It is supported by large beams of timber, firmly placed in the ground, and strongly fastened together, the distances between them being filled with very large stones; and the mole is strengthened by a vast bank cast up against it.

Purmer, or Purmeren, and the Beenister, are both drained lakes: the latter is encompassed by a channel from 4 to 8 rods broad, and is joined to the former by a bridge at the south end. Purmer is about 5 miles long, and above 2 broad. The Beenister contains 7090 acres besides the highways, dikes, and canals, which surround and cross it in several places. It lies between Purmer and Edam, and was a lake till the year 1610, when, after four years labour, and vast expence, (the banks, by which the water thrown out by the mills was confined, having been broken, after the work was half done,) it was made dry land; and is now so planted with gardens, orchards, rows of trees, and fertile inclosures, that Sir William Temple says it is the pleasantest summer landscape he ever saw. There were no fewer than thirty mills employed to drain the Beenister.

We come now to the consideration of the agriculture, fisheries, manufactures, and commerce of the province of Holland. The agriculture of such a country, where the soil and climate are so very moist, cannot be expected to be considerable, or to present many instructive or interesting topics: in some respects, however, it deserves notice, particularly in what regards the pasturage of New Holland, and most especially of the drained lands.

In this province, few lands are held in fief, or by homage, and the women being very fruitful of children, and the men generally dividing their landed property among them, estates are for the most part small. The farms are also small: the farm houses are neat, sheltered and concealed by small clusters of trees, and included, together with their gardens and orchards, in a perfect green fence. The fields are separated from each other, and from the road, neither by hedges or walls, but by deep ditches filled with water, over which are laid small bridges, that may be opened in the middle by a sort of trap door, raised and locked to a post, to prevent the intrusion of strangers. The roads, in many places, are made on the dike of the canal, the fields being frequently between five and six feet below the level of the road; but the communication between most of the farm houses and the villages and towns, and also between the several parts of the same farm, is often entirely by means of small canals. The most magnificent public roads in Holland are those in the vicinity of the Hague. The road from this place to Scheveling is pointed out by the Dutch as an object of admiration to strangers: the length of this avenue, for it can hardly be called a road, is nearly two miles, and its breadth rather more than 20 paces: it is a perfectly straight line, so that the entrance of the road commands a view of the whole; and the church of Scheveling, a picturesque object, terminates the prospect. It is shaded on each side by beeches, limes, and oaks, of an astonishing growth, which are so closely and skilfully planted, that they form to appearance an impervious forest. From Delft to the Hague, the road is magnificently grand. It is of sufficient breadth to admit four or five carriages abreast, shaded on both sides by lofty rows of trees, kept in excellent repair, and so level, that not the least inequality of ground is to be perceived.

There is very little land under tillage in the province of Holland, as may be easily imagined from the nature of the soil and climate; and what is under tillage is almost exclusively confined to South Holland. The crops principally cultivated are wheat, madder, tobacco, hemp, flax, clover, &c. The country adjacent to Gravesande, not far from the mouth of the Maese, is reckoned to produce the best wheat, as well as the sweetest grass, in South Holland. Madder of most excellent quality, naturally as well as prepared, in a most superior manner, has long been a productive and famous crop in Holland. Tobacco is not so extensively or carefully cultivated as formerly. Hemp flourishes remarkably well, the depth and moisture of the soil being admirably adapted to the luxuriant growth of this plant. Oudewater, about seven miles to the south of Woerden, upon the lesser Yssel, in South Holland, is noted for good hemp produced on its soil. Flax is grown, not only for the purpose of manufactures, but also for its seed, though some of the other provinces in the Netherlands are more remarkable for this crop than Holland. The same remark applies to clover.

The pastures of Holland, especially as has been already remarked, of North Holland, are perhaps unrivalled for the abundance and luxuriance of the grass they produce. From it they obtain milk, cheese, and butter, all of excellent quality. Mrs. Radcliffe remarks, that on her way from Helvoetsluys to Rotterdam, she passed now and then a waggon filled with large brass jugs, bright as new gold; in these vessels, which have short narrow necks, covered with a wooden stopper, milk is brought from the field, throughout Holland. It is always carried to the towns in light waggons or carts, drawn frequently by horses as sleek and well-conditioned as those in our best coaches. The butter of Holland is of a very superior quality: the greater part of it is salted and barrelled for exportation; Beenister is noted for the excellence of this article. There are several kinds of cheese made in Holland, some of which are rich and highly esteemed, and some made from milk, which has previously supplied the butter, of course very inferior in quality. Leyden, Gouda, Edam, Gravesande, and Hoorn, are famous for their cheese: from the last place, vast quantities both of cheese and butter are exported to Spain, Portugal, and other countries, epecially during their annual fair in the month of May. The cheese made in Holland is of two sorts, red and white; the red is much esteemed, and somewhat resembles the Parmasan ; it is made into large and small shapes ; the former weighs from 18 to 20, and the latter from 6 to 8 libs : the white cheeses weigh from 6 to 7, and the richest kinds are excellent as toasting cheeses. Besides the common Dutch cheeses, there are some called *Kanterkaas* ; these are of various sorts, the principal of which are the green cheeses, the white of Leyden, the cummin cheese of Leyden, and the round cheese. In North Holland, about 18 millions of pounds of cheese were sold in the year 1801 : and at Gouda, in 1803, about two millions were sold. The cattle which produce such large quantities of excellent butter and cheese, are not indigenous, but for the most part are of the Holstein or Danish breed. In the vicinity of Hoorn they have a considerable trade in Danish cattle, which are imported lean, and fattened in the rich pastures round this place, and then driven to the other parts of Holland. The utmost attention is every where paid to the warmth and cleanliness of the milch cows, so that even in summer the animals appear in the meadows clothed with ludicrous care. The horses are principally from England or Flanders. The number of horned cattle in Holland, in the year 1804, amounted to 902,526, of which 252,394 were under two years of age. At that time it was generally believed that there had been a great decrease in the number of horses, sheep, and swine. The ancient race of sheep indigenous to the country, have long been improved by the introduction of foreign breeds ; but the soil and climate of Holland are not favourable to this animal : very little wool is exported, what is obtained from the sheep being chiefly consumed in the manufactures of the country. In some parts of Holland, bees are an object of much attention to the farmer, chiefly on account of the wax which they afford. A vast quantity of this article is annually gathered ; and the bleaching of it forms a considerable branch of industry among the poorer classes : a great deal of white wax was formerly exported to Spain. In connection with the agriculture of Holland, its horticulture must not be passed over : the mode of laying out the gardens is still very ungraceful and artificial ; the trees are bent and cut into a thousand fantastic shapes, and the flower-beds are of every form that can displease and disgust the eye of taste. There are generally abundance of stagnated canals, with puerile bridges thrown over them. But setting aside these points of inferiority, the people of Holland in several respects are excellent horticulturists, especially in what regards the culture and improvement of the most beautiful flowers. The rage for flowers, especially tulips, is not nearly so great or general at present as it was formerly. There is to be seen in the registers of Alcmaer, the record of a circumstance which deserves to be mentioned : In the year 1637, there were sold publicly in this city, one hundred and twenty tulips for 90,000 guilders : one of these flowers, called the Admiral of Enchuysen, with its root and offsets, was sold for 5200 guilders ; two others, called Brabanters, for 3800 guilders ; and one named the Viceroy sold for 4203 guilders. Not only the name and price of these flowers, but also their weight, are particularly set down in the registers of this city. The passion of paying exorbitant prices for flowers at length came to such a height in Holland, that the States were obliged to put a stop to it by severe penalties; many gentlemen having been ruined by that passion. The fruit of Holland, though abundant, is seldom of good quality : the humidity of the climate, as well as its rapid growth, from the richness of the soil, rendering it insipid.

The fisheries of Holland consist of those which are carried on near the coasts, and those which are carried on at a distance. The shores abound with excellent fish, particularly turbot and soals ; but for other fish, in consequence of the shallowness of the sea near the coast, the fishermen are generally obliged to go to the distance of more than five miles. The village of Scheveling is particularly remarkable for the number of fishermen whom it contains ; they are distinguished by their ruddy countenances and athletic limbs. The principal foreign fishery of Holland, formerly, was that of herrings : it was carried on from the ports of Dort, Rotterdam, Delft, Schiedam, Briel, Enchuysen, &c. The time of departure for the fishery was about the 24th of June. The cod fishery, which is still carried on to a considerable extent, commences in October and ends in April. It is carried on upon the Dogger Bank ; what is caught serves not only for the consumption of Holland, but forms one of its chief exports. The city of London consumes immense quantities of cod, caught by the Dutch. The whale-fishery was formerly vested in a company called the Northern Company; it afterwards became open and free ; but, like all the other branches of the fisheries and commerce of Holland, was destroyed by the revolutionary wars, and has not yet revived. It was chiefly carried on upon the coasts of Nova Zembla, as far as Davis Straits, and upon those of Spitzbergen, Greenland, &c. The vessels engaged in this fishery, during its flourishing state, were about 300 in number.

The chief manufactures of Holland are linens, (many of which, however, are made in Silesia) pottery and painted tiles, woollen cloth, leather, wax, snuff, sugar, starch, paper, &c. At Haerlem, there are considerable manufactories for the fabrication of fine linen cloths, dimity, satins, &c. which, though they have fallen off considerably, in consequence of the war and the measures of Bonaparte, still give employment to a number of workmen, and carry on a profitable trade with Brabant and Germany. The bleacheries of Haerlem have long been famous for the delicate whiteness which they give to linen cloths, large quantities of which are annually brought hither from all parts of the Netherlands and Germany to undergo this operation; and before the war between Holland and Britain, and the improvements made in the process of bleaching, by means of the oxymuriatic acid, much was sent from Ireland and Scotland. The principal inhabitants of Amsterdam, and other neighbouring places, also send their linen to be washed and bleached at Haerlem. The superior whiteness of the bleacheries of this town is attributed to some peculiar quality in the water of the lake of Haerlem. Some woollen cloth is manufactured at Delft, and other places, but Leyden is the principal seat of this branch of manufacture: here is a large building for examining and sealing the cloth. This manufacture is at present in a very decayed state; half a century ago, there were annually made upwards of 100,000 pieces : and many thousand industrious workmen were employed. The woollen manufactures, in all Holland, at the beginning of the 18th century, amounted to about 200,000 pieces of broad cloth, serges, baize, stuffs, &c. whereas in the year 1802, they did not exceed 20,000 pieces; and in 1804, the whole manufacture did not amount to 400,000 ells of cloth. The effects of this decay were strikingly evinced at Leyden, the population of which fell from 80,000 to 30,000. The manufactures of this city do not appear, even in their most flourishing condition, to have rivalled, in the fineness of their articles, the looms of England; but their coarse cloths found a ready sale on the continent, and the East and West India companies procured them ready markets in the other quarters of the globe. As the commerce of Holland declined, that of Britain increased; and the manufactures of Yorkshire deprived the manufactures of Leyden of the foreign markets to such an extent, that the Dutch merchants discovered it was for their interest to export English cloths in preference to the manufactures of their own country. The woollen trade of Leyden also received much injury on the continent, from the establishment of extensive looms in various parts of Germany and the Netherlands, which then ceased to draw any considerable supplies from Leyden. In the year 1808, the minister for the interior made a report to the king of Holland, on the state of the woollen manufactures, from which it appears that attempts were then making to improve the Dutch wool, by the introduction of Merino sheep, and to revive the woollen manufactures of Leyden. The manufacturers of this city are extolled for the durability, beauty, and excellent quality of their cloths and kerseymeres; and, from a passage in the report, it appears that Louis had conferred the golden prize of honour on the Leyden cloth. This report also gives some information respecting other branches of woollen manufacture in Holland. Bocking frize, formerly imported from England, seems to have been made at Amsterdam; the blankets of Leyden are mentioned as of excellent quality; and the silver prize of honour seems to have been conferred on the camlet hall of that city.

Delft was formerly famous for its manufacture of earthen ware, which rivalled the porcelain of China, and was generally sought after and esteemed throughout Europe, for its elegance and beauty. In the year 1800, there were scarcely 500 persons employed in the potteries of this place; whereas, in their most flourishing days, they gave subsistence to upwards of 10,000. The principal causes of this astonishing decay, independently of those which have produced a general decay of manufactures and commerce in Holland, are the immense quantities of porcelain, which, for a century and a half, have been imported into Europe from China; and the rival manufactures, which, during that time, have been established in Germany and England. The earthen ware of Staffordshire was some years ago so much approved of in Holland, that the states-general, in order to protect the manufactures of Delft from absolute ruin, were obliged to lay duties on its importation into the republic, which were so severe as to amount almost to an entire prohibition. Glass, especially glass toys, are made in several parts of Holland. The glass-house in Rotterdam was formerly deemed the best in the Seven Provinces. It made a number of glass toys and enamelled bowls, which were exported to India, and exchanged for china ware, and other oriental commodities. From the universal practice of smoking among the Dutch, it may naturally be supposed that manufactures of pipes are by no means uncommon. There is a noted manufacture of them at Gouda; they are remarkably neat, and a very extensive trade of them is carried on. They make also in the neighbourhood of this city a vast quantity of bricks and tiles, the latter principally what are called Dutch tiles. At Enchuysen, salt brought from Brittany is refined.

The breweries and distilleries in Holland are numerous and extensive. Delft, Gouda, and Muyden, are particularly celebrated for their beer. The beer made in Delft is chiefly consumed in that place and the adjacent country. In the 15th century, the town of Gouda had 350 breweries, from which Zealand and a great part of Flanders were furnished with beer. In 1518, they had decreased to 159; in the year 1522, there were 153; in 1588, there were 126; and in the year 1803, there were only two. These, however, make beer of excellent quality; imitating London porter with tolerable success. If, however, it is drank out of the cask, it is very inferior; but after it has been in bottles for some time, its taste is nearly as agreeable as London bottled porter, from which it is difficult to distinguish it. Muyden is noted for good beer, called Flemish physic. The distillation of ardent spirits is the sole manufacture which has increased in Holland. In 1775, there were at Scheidam, particularly noted for its Geneva, 120 distilleries; in the year 1792, 220; and in the whole province of Holland 400; each of these distilleries yielded annually 4492 ankers of gin. The whole distilleries of the seven provinces would produce annually 2,152,672 ankers; but the want of grain renders it necessary to reduce this quantity one-third, which leaves 1,400,000 ankers, of which 456,000 are consumed in the country, and the remainder exported.

There are a great number of sawing mills in Holland, particularly in the vicinity of Rotterdam. They are lofty and rather pleasing objects, the mill generally rising from the top of a substantial building two or three stories high. Some of them are painted in a whimsical taste, and others adorned with grotesque figures. During the flourishing state of Holland, Saardam, where Peter the Great acquired a practical knowledge of the art of ship-building, derived great wealth from that trade; but it is now almost annihilated.

The miscellaneous manufactures of Holland, not yet enumerated, most of which, however, are confined to Amsterdam, are stuffs embroidered with gold and silver, damasks, brocades, mohair, silk, &c. and particularly the preparation of drugs for dyeing, painting, and medicine, such as camphor, vermilion, sulphur, borax, lapis lazuli; likewise pitch, tar, rosin, spermaceti, &c. The oil mills are numerous. The cordage made in Holland is very good; and Dutch paper, particularly cartridge paper, is still exported in very great quantities, even to England, though we now rival or excel them in the manufacture of fine writing paper. The preparation of diamonds, that is, the cutting, polishing, and grinding of them, is confined to Amsterdam, where many artists are employed for that purpose. The manufacture of skates is also of some consequence in Holland.

The United Provinces were formerly pre-eminent in commerce; and the province of Holland, from its greater extent, population, and riches, as well as from its possessing near all the sea-ports, enjoyed nearly the whole of this commerce. Long before the French Revolution, however, the trade of the United Provinces had begun to decline; and the circumstances of that tremendous event may be said to have utterly annihilated the commerce of Holland. While it lasted, it was carried on principally with France, England, Spain, and Portugal, the Levant and Mediterranean states, Russia, Sweden, and Denmark; and with Germany, by means of the Elbe, the Ems, the Weser, the Rhine, and the Meuse. The inland trade with Germany, by the canals and the Rhine, is almost the only branch which has escaped the ravages of war. Of this, the most remarkable feature consists in the vast floats of timber which arrive at Dort from Andernach and other places on the Rhine. The length of these rafts is from 700 to 1000 feet; the breadth from 50 to 90; and 500 labourers direct them, living in a village of timber huts erected on the rafts for their reception. The navigation is conducted with the strictest regularity. On their arrival at Dort, the sale of one raft occupies several months, and frequently produces upwards of 30,000 pounds sterling. The commerce of Holland was either transit or direct. The articles of direct commerce were supplied either by her agriculture, such as butter, cheese, &c. or by her manufactures, as prepared drugs for medicine, dyeing, &c. linen, woollen cloth, paper, &c.; or they were supplied by her East India possessions and her fisheries. In return, Holland received either what was necessary for her own consumption, particularly corn, or those articles which she again distributed over the rest of Europe. In the year 1807, nearly one million pounds of silk were imported into England from Italy through the medium of Holland.

The province of Holland is extremely populous; perhaps more so than any other part of Europe. In the year 1515, it contained only 45,000 houses. In the year 1732, the number of houses was increased to 163,462. De Witt, in his work on the true interests of Holland, informs us, that, in the year 1622, the States laid a poll tax upon all inhabitants, none excepted but strangers, prisoners, and vagrants, and those that were on the other side of the line; yet were there found in all South Holland no more than 481,934, although the instructions of the commissioners appointed for that purpose were very strict. The following are the particulars, as registered in the Chamber of Accounts:

| | |
|---|---|
| Dort, with its villages | 40,523 |
| Haerlem, with its villages | 69,648 |
| Delft, with its villages | 41.744 |
| Leyden and Rhineland | 94 285 |
| Amsterdam, and its villages | 115,022 |
| Rotterdam, and its villages | 28.339 |
| Gouda, and its villages | 24,622 |
| Gornichem, and its villages | 7.585 |
| Schiedam, and its villages | 10,393 |
| Schoonhoven, and its villages | 10,703 |
| Brill, with its villages | 20,156 |
| The Hague | 17,430 |
| Heusden | 1,444 |
| | 481,934 |

De Witt supposes that West Friesland, or North Holland, might have the fourth part of the inhabitants of South Holland, or 120,483, which, added to 481,934, would give 602,417 as the total population of the province of Holland in the year 1622. This, however, in the opinion of De Witt, was far below the truth, and he raises the number to 2,400,000. This must be an exaggeration; and it is given here, only for the purpose of adding De Witt's calculation of the proportions of this number engaged in different employments: according to him, 450,000 were employed, directly or indirectly, in the fisheries: 200,000 were supported by agriculture, inland-fishing, herding, hay-making, turf-making, and by furnishing materials for these operations: 650,000 in manufactures: 250,000 in navigation and trade: 650,000 in miscellaneous employments; and 200,000 gentry, magistrates, soldiers, &c. In the year 1732, the population of Holland certainly did not exceed 980,000. In the year 1796, an estimate of the population of the Seven United Provinces was made by order of the National Assembly, which we shall give entire, for the purpose of comparing the population of Holland with that of the other provinces.

| | | |
|---|---|---|
| Guelderland, in the towns, | 64,994 | |
| in the flat country | 152,834 | |
| | | 217,828 |
| Holland, in towns | 495,017 | |
| in the flat country | 333,525 | |
| | | 828,542 |
| Zealand, in towns | 39,978 | |
| in the flat country | 42,234 | |
| | | 82.212 |
| Utrecht, in towns | 45,204 | |
| in the flat country | 47,600 | |
| | | 92.804 |
| Friesland, in towns | 44,824 | |
| in the flat country | 116,689 | |
| | | 161,513 |
| Overyssel, in towns | 41,805 | |
| in the flat country | 93,255 | |
| | | 135,060 |
| Groningen, in towns | 23,770 | |
| in the flat country | 90,785 | |
| | | 114,555 |
| The country of Drent, in towns | 5,789 | |
| in the flat country | 33.883 | |
| | | 39.672 |
| Dutch Brabant, in the towns | 48,711 | |
| in the flat country | 159.466 | |
| | | 2[illegible]8,177 |

The total is 810,192 in towns, and 1,070,271 in the flat countries, making the entire population of the United Provinces, in the year 1796, to be 1,880,463. The population of the province of Holland, as stated above, in the year 1732, was 980,000, and in the year 1796 it was 828,542, which shews a decrease of 151,458 inhabitants, equal to one-thirteenth of the whole population.

The people of Holland may be divided into the following classes:—the clowns, or boors, who cultivate the land; the mariners, or skippers, who navigate the ships and inland boats; the merchants and traders, who fill the towns; the *renteeners*, or men that also live in towns, upon the rents of their estates; and the gentlemen, officers of the army and navy, magistrates, &c. The boors feed chiefly on herbs, roots, and milk. The other classes drink enormous quantities of tea and coffee, or, more properly speaking, of lukewarm water scarcely coloured. A great quantity of spirituous liquors are also drank; 456,000 ankers of geneva being annually consumed in the province of Holland. The class of gentlemen, or nobles, is very limited; most of the families having been extinguished in the long wars with Spain.

Of the characteristic manners and customs of the people of Holland we can only mention a few. To every house throughout North Holland there are two doors; one of which is never opened but when a corpse or a christening is carried from the house, while the other serves for the ordinary purposes of the family: this custom is peculiar to North Holland. The houses in almost every part of the province have a gay appearance, the windows and doors in general being painted green. The most scrupulous cleanliness is practised respecting them; not only the windows, but the whole front of the houses, in most of the towns, is generally washed two or three times a-week, by engines for that purpose, which are abundantly supplied with water from the canals; and the same care is extended to the pavement of the streets in which the more opulent inhabitants reside. A Dutch house, in the old style of building, such as they are seen in Leyden more particularly, is generally six stories high, the three first of which are of an equal breadth, but of unequal heights; from the third story the roof rises to a point, and the rooms in this part of the house necessarily diminish in size as they approach to the top of the building. The front wall of the upper apartments projects so much from the roof as nearly to hide it, unless viewed in profile; and the exterior of each room diminishes, till that of the attic story is two-thirds less than the basement. To the aperture of the uppermost room is commonly fixed a small crane, for the convenience of hoisting up wood and turf, and these cranes sometimes have grotesque figures carved upon them. In the large and commercial towns, it frequently happens, that apartments that would grace the mansion of a prince have no other views from their windows than the dead walls of a warehouse, used as a magazine for stock-fish, skins, tobacco, &c. so that the eye may turn from the works of Rubens and Titian to these disagreeable and disgusting objects.

The custom of smoking is so prevalent in Holland, that a genuine Dutch boor, instead of describing the distances of places by miles or hours, says, they are so many pipes asunder. Thus a man may reach Delft from Rotterdam in four pipes; but, if he goes on to the Hague, he will smoke seven during the journey. Adjoining to their theatres is a room where refreshments are to be sold, and here the lovers of tobacco resort, to smoke their pipes between the acts. Their rigid attention to cleanliness, and bigoted attachment to smoking, jointly give rise to a most inconvenient and disgusting custom. After dinner, there is placed on the table, along with the wine and glasses, a spitting-pot, which is handed round as regularly as the bottle. All Dutchmen of the lower classes of society, and not a few in the higher walks of life, carry in their pocket the whole apparatus that is necessary for smoking: a box of enormous size, which frequently contains half a pound of tobacco; a pipe of clay, or ivory, according to the fancy or wealth of the possessor; if the latter, he carries also instruments to clean it; a pricker to remove obstructions from the tube of the pipe; a cover of brass wire for the bowl, to prevent the ashes, or sparks, of the tobacco from flying out; and sometimes a tinder-box, or bottle of phosphorus, to procure fire in case none is at hand.

When a woman is brought to bed, a bulletin is daily fixed to her house, for the space of a fortnight, or longer if she recovers slowly, which contains a statement of the health of the mother and child. This bulletin is fastened to a board, ornamented with lace, according to the circumstances of the person lying in; and serves to answer the inquiries of friends, and to prevent unnecessary noise near the house. When a person of consequence is dangerously ill, a bulletin of health is generally affixed to their house; but, unless it is a child-bed case, the board is not ornamented with lace.

The women in Holland, in general, are lovely rather than beautiful; in their persons they are well formed; their complexions are fair, and their features regular, but their countenances are inanimate. Women are shorter-lived in Holland than men; and after twenty-five generally lose all their beauty. The management of children is very absurd and injudicious. The air of the country is regarded as so prejudicial to them, that for the first two or three months they are never taken abroad; and, during this period, the windows of their apartments are kept invariably shut. Their dress consists in flannel rollers, girt very tightly about their bodies, and these rollers are farther covered with a large flannel wrapper, bound three or four times round the body of the infant, and fastened with pins at its feet. The use of water is rigorously denied them. Thus managed, they are sickly, squalid objects. Children, particularly females, are frequently indulged in the pernicious use of *chauffepieds*, or stoves, without which a Dutchwoman could not exist, and this adds to their unwholesome appearance. We may remark, by the bye, that the advances of Britain in civilization and useful knowledge are perhaps in no instance more decidedly conspicuous, than in the improved management of children. Many of our readers must remember the period, when British children were almost universally clothed and treated as Dutch children still are.

The female dress, such as it was generally worn in Holland nearly two centuries since, is not unfrequently still seen on the daughters of the ancient stock of burghers. The hair is bound close to the head, and covered with a small unornamented cap, with large plates of thin gold projecting from each side of the forehead, and a plate in the middle; ponderous ear-rings, and necklaces of the same metal; gowns of thick silk, heavily embroidered, and waists of unnatural length and rotundity; hats of the size of a small Chinese umbrella, gaudily lined within; sometimes these hats are set up in the air like a spread fan; yellow slippers, without quarters at the heel. Children, and women of seventy, are frequently seen in this preposterous dress. The women of rank or fortune are very fond of ornamenting their dress with rare and valuable jewels. These, as well as the gold plates worn by the lower orders, are of great antiquity, and are most carefully handed down from generation to generation.

The Dutch language is evidently of Gothic origin, but it is little known out of the United Provinces. Dutch literature will be more properly considered in the article NETHERLANDS; where, indeed, every thing relating generally to the history and statistics of the Low Countries must be sought for; as, in the present article, we confine ourselves, as much as possible, to the province of Holland. With respect to the encouragement given to literature, this province was formerly very remarkable. Leyden, Amsterdam, and the Hague, may be seen on the title-pages of the most valuable works, in Latin and French, which were printed during the 17th, and the beginning of the 18th centuries. The Elzivers, justly celebrated for the correct and beautiful editions which they have given to the world of the best writers of antiquity, resided in Leyden, and ennobled its press by the elegant specimens of typography, which, for the space of a century, appeared from their press. During the bright period of French literature, when the writings of Voltaire, Rousseau, D'Alembert, &c. were eagerly sought after by the learned and curious of Europe, the booksellers at the Hague and Amsterdam multiplied the editions of these authors, and carried on a lucrative trade with their works. Haerlem is one of the places which lays claim to the honour of the invention of the art of printing; but at present the literary character, as well as the bookselling and printing trade of Holland, are at a very low ebb. There is one university in the province of Holland at Leyden, and an inferior college at Amsterdam.

Though the province of Holland is now only a part of the kingdom of the Netherlands, and of course has lost many of its peculiar privileges and institutions, yet some particulars respecting its government require to be noticed, as they still remain under the constitution of the Netherlands. Deputies of the nobles, and those of the towns and country, are elected for the parliament of the kingdom. There are also provincinal councils of state for South and North Holland. For the administration of justice, there are two courts held at the Hague; namely, the court of Holland, and the high council. The nobles of Holland are subject to the jurisdiction of this court; an appeal lies to it from the sentences of the inferior courts. The high council of Holland judge peremptorily and definitively of all cases brought before them by an appeal from the court of Holland. Among the laws of this province the following deserve notice. No person can be arrested for debt, who has not been summoned regularly three times, with the interval of 14 days between each summons; and six weeks further must elapse from the last official notification and demand of the debt, before the creditor is permitted to arrest or seize the effects of the insolvent person. By this mode of procedure, debtors are generally enabled either fully to settle their affairs, or to compromise with their creditors, so that few are sent to prison. No person can be arrested in his own house in Holland, or even standing at the door of it, though all the previous citations should have been made; and should his wife be lying in, he is privileged, during her illness, to go abroad without molestation.

The religion of Holland is Calvinism. In it there are two provincial synods; one for South Holland, and the other for North Holland. The whole province being divided into a great many classes, composed of the deputies of five or six neighbouring churches; each class sends four deputies to the respective synods, two ministers, and two elders. The synods meet twice a year, and a political commissary attends their meetings. The ministers are paid by the magistrates. Their salaries are small; few, even in the cities, having 200*l.* a-year, while in the country they have generally 60*l.* or 70*l.*

The taxes of the province of Holland are very heavy. They amounted in 1795 to 24,000,000 of guilders, or 2,000,000 sterling, which, on the supposition that the population was 800,000, formed an average of 2*l.* 10*s.* each person; but a large portion of this taxation is, in fact, paid by foreigners, who consume the articles taxed. Among the taxes really paid by the inhabitants themselves are the following: A land-tax of about 4s. 9d. per acre; a sale-tax of 8 per cent. upon horses; 1¼ per cent. upon other moveables; and 2½ per cent. upon land and buildings; a tax upon inheritances out of the direct line, varying from 2½ to 11 per cent.; 2 per cent. upon every man's income; an excise of 3*l.* per hogshead on wine, and a charge of 2 per cent. on all public offices. The excise upon coffee, tea, and salt, is paid annually by each family, according to their number.

The province of Holland, as well as all the countries watered by the Meuse and the Rhine, were for a long time divided into small earldoms; but in the year 923, Theodoric was appointed Count of Holland by Charles the Simple, King of France, and the title became hereditary. The most frequent wars of the counts of Holland were with the Frisons, a part of the old Saxons. There were also frequent contests between the counts of Holland and Flanders, concerning the possession of the islands of Zealand. The counts of Holland, likewise, were frequently opposed by their own nobility. In order to break their power, they not only demolished many of their castles and strong holds, but also, about the year 1200, built several cities, and gave freedom to the inhabitants of the adjacent country; or even to foreigners, who would come and dwell in those cities. They were thus freed, not only from all taxes due to the counts themselves, but also, when they had dwelt in the cities a year and a day, from the vassalage they were under to their own lords. The counts, besides, gave especial privileges to those cities; but the inhabitants were not permitted, though at their own charge, to set up gates or walls to defend their cities, unless they purchased the privilege from the counts. Hence proceeded the difference between walled and unwalled cities in Holland; and also, that the counts being afterwards jealous of the former, destroyed many of them entirely, and pulled down the walls of others. Philippina, daughter of William III. Earl of Holland, was married to the Prince of Wales, afterwards Edward III. of England. This king afterwards contested the earldom of Holland with Margaret, his sister-in-law. In the year 1417, Jacquelin, heiress of Holland, married John IV. Duke of Brabant; but her uncle John of Bavaria, who had resigned the bishopric of Liege, in the hopes of espousing her, contested the succession. A kind of anarchy followed. Jacquelin went to England, where, in 1423, she married Humphrey, Duke of Gloucester; but this marriage having been annulled by the Pope, she married, in 1432, Borselen, stadtholder of Holland. But having no children by any of her husbands, Philip the Good, Duke of Burgundy, who was her first cousin, obliged her to give up the administration and government of her states, and at her death inherited them. Soon afterwards, Holland, with the other large possessions of the House of Burgundy, fell by marriage to the House of Austria. Its history, from this period, must be sought for under the article NETHERLANDS. See *Statistical Account of Holland*, by R. Meterlecamp, 1804; De Witt's *True Interest of Holland;* Sir William Temple's *Observations on the Netherlands;* Mrs Radcliffe's *Journey through Holland in* 1794; *A Tour through the Batavian Republic in* 1800, by R. Fell. (W. S.)

HOLLAND, NEW, an island in the South Pacific Ocean, which some geographers have called a continent, from its immense extent. Its general outline somewhat approaches to that of a spherical triangle. It stretches from east to west above 2600 miles, between Sandy Cape and the entrance of Sharks Bay; and its length surpasses 2000 miles, from Cape York on the north, to Wilson's Promontory in 39° 10′ south latitude. New Holland was originally called the Great Southern Land; its present name was imposed by the Dutch, who navigated the coasts at an early period; but it has lately been proposed to alter its appellation to Notasia by Mr Pinkerton, and to Terra Australis by Captain Flinders, neither of which will probably be adopted. Nothing whatever being known of the interior, and very little with certainty of the skirts of the island, it is only divided into portions, called by the names of their supposed discoverers, and the vessels which they commanded; as, Arnheim's, Van Diemen's, De Witt's, Endracht's or Corcord's, Edel's, and Leuuin's land, on the north and west, and Nuytz's land on the south. The east coast was surveyed generally by Captain Cook, and called New South Wales; and the portion from Cape Howe, the south-east extremity, to Nuytz's Archipelago, where the recognition of that navigator is supposed to have terminated, occupying between 700 and 800 miles, was examined by D'Entrecasteaux, Captain Flinders, and M. Baudin, and also some other officers.

New Holland is begirt with small and sterile islands. A large portion of the coast is inaccessible, either from rocks or shoals, or the precipitous formation of the shores; but the greater part is low and sandy, exhibiting a barren aspect. A few lofty headlands project into the sea; bays and harbours are rarely to be seen, and navigable rivers are scarcely yet discovered. The northern coast is indented by the immense gulf of Carpentaria, stretching 400 miles in width at the entrance, and penetrating 500 miles into the land; which, although it is rudely laid down in the Dutch charts of the 17th century, was first completely explored by Captain Flinders in 1802. Sharks Bay, where Dampier anchored in 1699, was lately ascertained by the French to be 50 leagues deep. And besides these, there are several less capacious on the south coast, as King George's Sound, Port Philip, and Western-port, at the second of which a British settlement was attempted in 1804. On the east coast, Botany Bay is the most important, from the flourishing establishment connected with it; and two other inlets of a different description on the south coast merit notice, from being supposed the entrance to some great river dividing New Holland asunder. One of these, called Bonaparte's Gulf by the French, and Spencer's Gulf by the English, 48 miles wide at the mouth, penetrates the land 185 miles, terminating in a point exactly opposite to the bottom of the Gulf of Carpentaria. The other, separated from it by York's Peninsula, of which the extreme point lies in 136° 52′ East Longitude, is of smaller dimensions. The tide flows 40 miles up Hawkesbury river, falling into Broken Bay near Port Jackson, whither it is navigable by the largest vessels, and still farther by those drawing nine feet water. It is the most important river hitherto seen in New Holland; and, from the floodings above, sometimes overflows those parts of the banks 40 or 60 feet above its ordinary level, thereby committing great devastation. King William's River, on the west coast, is now conjectured to be little more than a creek, whose narrow entrance is obstructed by rocks.

Nothing can be more repulsive than the bleak and dreary appearance of thousands of miles occupied by the shores of New Holland. The earth is parched, vegetation stunted, and animal life seems incapable of being supported, from the universal scarcity of subsistence. Its low, uniform, and sterile aspect is such, that many conceive the whole has only been recently reclaimed from the sea. Nor is it so with the continental part of New Holland alone; for, amidst the numerous islands on the south, "nothing smiles to the imagination; the soil is naked; the heavens burning pure and cloudless; the waves agitated but by nocturnal gales. Man seems to have fled these ungrateful regions; and the navigator, terrified by dangers incessantly renewed, turns aside his weary eyes from the miserable shores." Yet, admitting that the exterior is of later origin, we must reflect on the vast extent of the interior yet unknown, where lofty mountains, wide rivers, and thick forests, may all be frequent. A greater portion is unexplored than equal to the course of the longest river in the world; and possibly its streams may be received in lakes, discharged by subterraneous channels, or absorbed in sandy deserts. We are aware, indeed, that, in the warmer climates, islands, which are the work of an inconsiderable insect, arise in the seas; that they become a resting place for birds; decomposition and fertilization follow; the seeds of plants are conveyed thither, and the deciduous parts of vegetables are not slow in forming a new soil. Neither is it improbable that volcanic eruptions may form a nucleus or substratum for future accessions. Still these accessions are so gradual, that many ages would be required for the formation of so great a country as New Holland. Besides, the appearance of the coast cannot be rigorously applied to the interior; and those minerals supposed to enter the constitution of primitive mountains are discovered here.

We are not enabled to give any specific account of the mineralogy of this country. Wilson's Promontory consists of granite; there are several small islands, some of which are granitic, and some volcanic; and coal is discovered near the surface. Coloured precious stones are also said to have been found in different parts, but we do not know whether their precise quality has been ascertained.

In so far as the country is yet explored, the vegetable creation is diffused more rarely than under corresponding latitudes, and fewer products are convertible to the use of mankind. It is disclosed only in scanty patches, where the soil has undergone amelioration; and there it appears in all possible variety, from the coarsest grass creeping on the ground, to forests consisting of trees of immense girth and altitude. It is said of the eastern parts, that "all the plants of this country are evergreens, and numbers of them are to be seen covered with blossoms at all seasons of the year." M. Leschenault remarks, "that in the districts hitherto visited, and especially the western coast, there have never been found, in great masses, either the majesty of the virgin forests of the New World, the variety and elegance of those of Asia, or the delicacy and freshness of the woods in the temperate countries of Europe. Vegetation is in general dark and sombre; it resembles the shade of our evergreens or copses. Fruits are for the most part ligneous; the leaves of almost all the plants are linear, lanceolated, small, coriaceous, and spiny. This peculiar texture springs from the aridity of soil and climate; and it is doubtless owing to the same causes that cryptogamous plants are so rare." Most of the plants of New Holland constitute new genera; and those belonging to genera already established are almost as many new species. Their numbers and variety are amply described in the works of M. Labillardiere and Mr Robert Brown, to which we shall refer for illustrations. A plant approaching the qualities of coffee has been found, two species of tobacco, and a kind of indigo. Odoriferous gum exudes copiously from a tree abundantly disseminated, which is used for different purposes by the natives, and has gained some credit among the settlers for curing dysentery. Wood of beautiful colours, fit for the finest cabinet work and inlaying, is common; and other kinds have been employed in building vessels. But amidst the great diversity of plants, only some small berries, a few roots, and leaves, have yet been found, which are suitable food. The climate of New Holland is particularly noxious to European fruits, as most of those introduced have speedily perished. Grain, however, succeeds admirably, producing a certain and luxuriant harvest; though the soil for the most part is soon exhausted, and some of what was once brought under culture is now completely abandoned.

A field equally new is presented in the animal world, where an infinity of beings are beheld on this continent, its shores, and islands, that never were seen before. Mollusca are so numerous, that, on one of the latter, the French voyagers collected 180 species. Great shoals of whales and dolphins fill the seas, but in many parts they are rare. The phocæ are so multiplied, that profitable fisheries have been instituted for their skins and oil, though it is so indiscriminately followed, in destroying the young, as to threaten the extirpation of the genera. Among birds, the black swan, cassowary or emu, mountain eagle, and menura, are the most remarkable. The first, which is black as jet, except two or three white feathers of the wings, covers the lakes and rivers in flocks during the greater part of the year. The emu is seen both on the continent and the islands; and there is sometimes found an enormous nest, two or three feet in diameter, belonging to an unknown bird, perhaps of the flamingo kind. Quadrupeds are exceedingly rare, both in species and numbers, compared with the extent of the country. Besides the dog, which is akin to the shepherd's dog of Europe, and never barks, it is supposed that another carnivorous animal of somewhat larger size approaches the coast, which has not been seen. The members of the last French expedition having prepared to pass a night on Edel's land, inform us, that "suddenly a terrible roaring froze us with terror; it resembled the bellowing of an ox, but was much louder, and seemed to come from the neighbouring reeds." Most probably this was an alligator, both from the sound and situation. The greater proportion of the quadrupeds of New Holland, though absolutely new and unknown in other parts of the world, belong to the opossum tribes. Those attracting most attention are the kangaroo of various species; the wombat, and a singularly formed creature, the paradox or duck-billed ant-eater. The first is hunted for the sake of its flesh; the second has been domesticated by the settlers; the third, an amphibious animal, is now found more abundant in the late excursions which have advanced furthest into the interior. Perhaps we should add to the brute creation those introduced into New Holland since the year 1788. Three cows and a bull having strayed into the forests, propagated there, and many thousands of wild cattle are seen in great herds, which it is dangerous to approach. Sheep and swine have succeeded well, but the country proves unfavourable to goats. So little of New Holland has yet been explored, as to admit a strong presumption of many interesting accessions to zoology, in addition to what it has already received.

The most striking peculiarities are beheld in that portion of the human race who inhabit these regions. In stature, the New Hollander is of the middle size; with a large misshapen head, slender extremities, and the belly projecting as if tumefied. The colour of the skin is reddish at birth, and then deepens almost to African blackness; but this is not uniformly so, and some are only of the copper or Malay cast: the hair is long and black, not woolly; the nose flat, nostrils wide, and the mouth immoderately large, with thick lips. These, added to bushy eyebrows, and other characteristics, give the natives a remarkable appearance: Dampier, who says "they are of a very unpleasing aspect, having no one graceful feature in their faces," seems inclined to doubt whether they should be ranked with the human race; and Mr Collins instances "one man, who, but for the gift of speech, might very well have passed for an oran-outang: he was remarkably hairy; his arms appeared of an uncommon length: in his gait he was not perfectly upright, and in his whole manner seemed to have more of the brute and less of the human species about him than any of his countrymen." Yet the physiognomy of the New Hollanders is not disagreeable; nay, it is said, that the delicacy which is to be found among white people may be traced on the sable cheeks of their females. Sustenance being so scanty, and clothing never employed, a decided effect is seen in the want of physical strength, and the consequences of perpetual exposure. In their persons all are filthy; the regular ablutions of many eastern nations are not performed, and the disgust of strangers is heightened by the custom of both sexes rubbing fish oil into their skins, as a protection against the legions of insects swarming around them. Tattooing, so general in the South Seas, is not practised by the New Hollanders; but they have a mode of raising tubercles on the skin, and both sexes ornament themselves with scars on the breast, back, and arms. The incisions, sometimes resembling the feet of animals, being made by the sharp edge of a shell, and kept open, the skin forms a large seam in healing, which is very distinguishable in youth, but is almost totally effaced by age. Men have the septum of the nose perforated to receive a bone, and are subjected to the extraction of some of the front teeth when they attain the age of puberty; and the women are deprived of the first two joints of the little finger of the left hand. Their personal ornaments are not numerous, consisting of the teeth of beasts or mankind glued to their hair, feathers, and the tail of the dog: and certain tribes divide their hair into parcels, matted together with gum into portions like the thrums of a mop. The men also ornament themselves, previous to a dance or combat, with broad stripes of white paint, used entirely according to taste, without any definite fashion. "Some," Mr Collins observes, "when decorated in their best manner, looked perfectly horrible; nothing could appear more terrible than a black and dismal face, with a large white circle drawn round each eye."

All are absolutely naked: Some of both sexes wear the skin of the kangaroo around their shoulders as a defence against the weather, but for no other purpose. A few of the men also go with a girdle about the loins, but the natural state of the whole is absolute nudity, and along with it, neither male nor female entertains any sense of shame. Nevertheless, violations of chastity seem infinitely more uncommon than where a full proportion of clothing is used. Their habitations are of the most miserable description, the best being only very long pieces of bark bent in such a manner, and the ends stuck into the ground, as to resemble the roof of a barn. Many have no other shelter than rocks, or trees, or even holes in the earth. The subsistence of those hitherto seen on the shores, is chiefly fish: they also feed on a kind of larva, or worm, lurking under the bark of trees, which is extremely disgusting to the view, but reputed a great delicacy; and they endeavour to ensnare wild animals. Captain Flinders found a race at King George's Sound, who seemed to live more by hunting than fishing; and there are inhabitants of the woods north-west of Botany-Bay, who make a paste of the fern root and ants bruised together.

The arts are here in the lowest stage: clothing and dwellings being unknown, all the ingenuity of these savages is concentrated in the means of obtaining subsistence and personal defence against their enemies. They construct canoes consisting of pieces of bark glued, or sewed together; and those seen at the bottom of the Gulf of Carpentaria, the largest of all, are thirteen feet and a half long, by two and a half broad. But many of the tribes seem quite unacquainted with them. Some tribes have also scoop nets and common nets for fishing: one of the latter, no less than 80 feet long and three broad, consisting of larger meshes and stronger twine than any English twine, was discovered at Glass-house bay on the east coast. Their arms are wooden lances, wooden swords, and wooden shields. One of their fishing implements is a four-pointed lance.

In regard to social order among these people, there is none: all we can affirm is, that they are divided into families, the oldest member of which claims a superiority over those immediately dependent upon him. There is no acknowledgment of chiefs; nor are any laws, except those of personal strength, recognised. It is by this means that even their marriages are accomplished. Instead of the courtship, suit, and persuasion, employed in other countries, the object of desire, generally of another tribe, is felled to the earth with a club, in some remote situation, and dragged in a state of insensibility to the dwelling, if such it may be called, of the husband. She becomes his wife, and frequently remains attached to him ever after. Sometimes, however, a more favoured lover is found, for whom the husband is deserted; and many of the men do not confine themselves to a single wife. Their offspring is named after some visible object, a quadruped, a bird, or a fish; and females are in the earliest infancy subjected to that mutilation of the little finger above referred to. Women are held in great subservience. They are the victims of all the barbarity which the superior power of savages can inflict, as is too incontestibly proved by the innumerable scars by which their bodies are covered. The New Hollanders either burn or bury their dead; and in general if a mother dies, while suckling her infant, it is buried alive in the same grave. They are utter strangers to religion: they have no images, nor can they be said to entertain any idea of a future state.

These people, however, are acquainted with some remarkable customs, of which the first and most conspicuous is, depriving youths at the age of puberty of an upper front tooth. Many ceremonies precede the operation, which are conceived to bestow the more valuable property of certain brutes upon them, and the operation entitles them to the privileges of men, with whom they are now enrolled. They equip themselves with long tails, in imitation of kangaroos; crawl on their hands and feet, and scrape up the earth like dogs; and remain motionless the whole night before the operation. After some preparation by the incision of the gum, the tooth is struck out by main force, but with considerable dexterity. The object of this custom is altogether uncertain; it has been supposed a tribute which one tribe could exact of another; but there is not sufficient evidence that this is the case. The custom is, however, widely, though not universally, diffused. Dampier affirms of those on the north-west coast, that "the two fore teeth of their upper jaw are wanting in all of them, men and women, old and young." Captain Flinders saw individuals at the south-west extremity, who had preserved all their teeth. However, around the settlements at Port Jackson, there are no exceptions. Here it is the right front tooth which is extracted. On the north coast, it is the left; and in the Gulf of Carpentaria, the men seen by Captain Flinders had lost both. We do not know whether the loss of members be deemed tributary among any nation where it is practised; but it has been lately asserted, that, on the death of the chief of the island of Owhyhee, each of his people must extract a tooth. The cause of mutilating the little finger of the women, according to the natives, is to avoid an embarrassment which would ensue to the fishing lines.

Another very extraordinary custom is the exact measure of retaliation observed for injuries. They have no laws; but blood must always be followed by blood. If children when at play receive a push, they return it by one of equal force; if a man is wounded, the aggressor is compelled to expose himself to the throwing of the sufferer's spear, or that of his friend; and if a man of one tribe should be unmercifully beaten by those of another, some individual of the latter must undergo a similar punishment. Yet there are many treacherous and midnight murders, and as savages sleep extremely sound, this is the moment selected for vengeance. It rather appears also, that the death of every individual, natural, accidental, or intentional, must be followed by shedding some person's blood. The disposition of the New Hollanders, as described by one who should know them well, is revengeful, jealous, courageous, and cunning. "The inhabitant of Port Jackson is seldom seen, even in the populous town of Sidney, without his spear, his throwing stick, or his club. His spear is his defence against enemies; it is the weapon he uses to punish aggression, and revenge insult. It is even the instrument with which he corrects his wife in the last extreme; for, in their passion, or perhaps oftener in a fit of jealousy, they scruple not to inflict death. It is the play-thing of children, and in the hands of persons of all ages. It is easy to perceive what effects this must have upon their minds. They become familiarized to wounds, blood, and death, and are repeatedly involved in skirmishes and dangers. The native fears not death in his own person, and is consequently careless of inflicting it on others." Nevertheless, it does not appear that the savages of New Holland are animated by the same treacherous ferocity as many of the neighbouring islanders. They are not cannibals: Strangers on the east coast, though surprised when asleep, have escaped with impunity. On the north coast they are more ferocious; but the sanguinary disposition of their European visitors may have sometimes excited the desire of revenge.

The New Hollanders consist of tribes inhabiting different districts; but, contrary to what is known among all savages still less barbarous, the right of individuals to territorial possessions, which are transmitted by inheritance, is apparently recognized.

The whole of this vast country seems inhabited only by a single race of people, intimately resembling each other in person, appearance, and manners, and who have not undergone the slightest change since Dampier's visit in the year 1688. In every different part that Europeans have landed, however, a different dialect is spoken; and these general conclusions are deduced from a number of instances comparatively small. Few natives consent to hold intercourse with strangers. Captain Flinders circumnavigated the whole coast of New Holland without having beheld a single woman from the time of leaving Port Jackson until his return. It has been conjectured, on very slight probabilities, that New Holland has been peopled from Papua. The natives of Botany Bay call themselves *Gal*, distinguishing their tribe or family by prefixing the name of the place which they inhabit. There is a tribe in Abyssinia designated Galla; the Highlanders of Scotland are denominated Gaël; therefore, without investigating the source of affinities in name among people so remote from one another, we shall simply suggest, that Gal, Gaël, or Galla, may signify nothing more than *people*. The present race presents a mortifying picture of mankind sunk in the lowest state of degradation, and, were we to judge hastily, we should say, they are incapable of civilization. The South Sea islanders have made wonderful progress in the arts and civilization, from the transient visits of Europeans. The natives of New Holland, who have witnessed the cultivation of the earth, the erection of houses, and the fabrication of apparel, for nearly thirty years uninterruptedly, still go naked, seek a precarious subsistence, and shelter themselves under rocks, or in caves, from the storm. Exceptions may be found, but they are only of a few individuals; nor is any change ever to be expected, but in selecting others in the earliest childhood; for so deeply rooted is their attachment to savage life, that a native carried to England, and supplied with every comfort, soon after his return stripped himself naked, and sought for greater enjoyments among his barbarous countrymen. See Australasia, Botany Bay, and Diemen's Island. (*c*)

HOLSTEIN. See Denmark.

HOLYHEAD, is a sea-port and market-town of North Wales. It is situated on a small island, on the north-west side of the island of Anglesey, and denominated in British *Caer Cybi*, or the fortified place of Cybi. The town consists of one principal street, with detached buildings. The collegiate, now the parochial church, is a handsome embattled cruciform structure, consisting of a chancel, nave, aisles, and transept, with a square tower, which supports a low flat spire. It appears to have been built about the time of Edward III. An assembly-room and baths, and a large new inn and hotel, have lately been opened. There is also here a free-school, established in 1757. This place seems to have been once in the possession of the Romans. On the summit of the mountain called Pen Caer Cybi, stands a circular building, (called *Caer twr*,) 60 feet in diameter, supposed by Pennant to have been a watch-tower. A long dry wall, 10 feet high, in many places faced and quite entire, runs along the side of the mountain. The precincts of the church-yard seem also to be ancient. Three of the sides of the parallelogram consist of massy walls, 17 feet high and 6 feet thick; the fourth is open to the harbour. At each angle is a circular bastion tower, and round the walls are two rows of round openings or oeillets, four inches in diameter, having the inside smoothly plastered.

As the island on which the town stands is the point of land nearest to Dublin, regular packets are stationed here for the accommodation of travellers passing between England and Ireland. The distance between Holyhead and Dublin is 20 leagues, a voyage which is generally performed in 12 hours, though sometimes in six. In stormy weather the packets have sometimes been two or three days at sea. Six packets are in the constant employment of the Post-office. One goes out every day except Thursday, and returns next morning. These packets are well constructed and well manned, so that serious accidents very seldom happen.

The harbour of Holyhead is formed by the cliffs under the church-yard, and a small island called Inys Cybi, on which there is a light. This harbour has been lately much improved. A pier has been built on the eastern side of it, to enable vessels to ride at anchor in four fathoms of water. In connection with this improvement, a new road has been made quite across the country from Cadnant island, near Bangor ferry, to the harbour, which saves seven miles. A new light-house has also been erected on a small island, or rather projecting rock, to the west of the head called the South Stack. The light, which is a revolving one, is about 200 feet above the level of the sea. In order to see the light-house, persons are wafted over by ropes in a kind of basket. The promontory, called the Head, is a huge mass of rocks excavated by the sea into the most magnificent caves, one of which, called the Parliament-house, is peculiarly fine. It is accessible only by boats at half ebb tide, and exhibits grand receding arches of different shapes, supported by magnificent pillars of rock. The promontory consists of lofty cliffs excavated into large caverns, which afford shelter to swarms of birds, such as pigeons, gulls, razor-bills, ravens, guillemots, cormorants, and herons. The peregrine falcon is found on the loftiest crags. As the eggs of many of the above-mentioned birds are considered as delicious food, and are therefore in high request, many of the people of the country earn their subsistence in the dangerous occupation of collecting the eggs. In order to accomplish their purpose, a strong stake is driven into the ground at a little distance from the edge of the cliff, and a rope is tied to it of sufficient length to reach the lowest nests. The adventurer ties the rope about his middle, and, with the coil on his arm, he seizes it with both hands, and gradually descends the cliff, placing his feet against its sides, and shifting his hands with great caution. When he reaches the nest, he holds by the right hand, and with his left seizes the eggs, and places them in a basket slung over his back.

The island on which Holyhead stands is called Holy Island, and received this name from the number of pious persons who were buried upon it. It consists chiefly of bare rocks and sterile sands. In the southern part of it, near *Four Mile Bridge*, is a quarry of serpentine or marble, containing a green amianthus.

The channel, which divides this island from the rest of Anglesea, is narrow, and may be forded at some places at low water. The great Irish road passes over a bridge called Rhyd y Pont.

The following is the population of the town in 1811 :

| | |
|---|---|
| No. of inhabited houses, . . . . . . | 539 |
| No. of families, . . . . . . . . . . | 701 |
| Do. employed in trade and manufactures, | 496 |
| Males, . . . . . . . . . . . . . . | 1317 |
| Females, . . . . . . . . . . . . . | 1688 |
| Total population, . . . . . . . . . | 3005 |

See Pennant's *Tour*; and *The Beauties of England and Wales*, vol. xvii. p. 245—253.

HOLY ISLAND, is an island situated about two miles from the coast of Northumberland, but belonging, in all civil matters, to the county of Durham : (See DURHAM, vol. viii. p. 201. col. 2.) It is situated opposite to the mouth of the brook Lindis, from which it received the name of Lindisfarne. By the Britons it was called *Inis Medicante*, and by the English Holy Island, from being the residence of several of the fathers of the Celtic church, and also from having been the episcopal seat of the see of Durham during the early ages of Christianity in Britain. The church of the monastery is in ruins. Its north and south walls are still standing, though they decline greatly from the perpendicular. The east wall is fallen, but great part of the west still remains. The arches are in general strictly Saxon, and the pillars on which they rest are short, strong, and massy. The pointed windows indicate that the building has been repaired at a subsequent period. The length of the body of the church is 138 feet; its breadth 18 feet, and 36 feet including the two aisles. Mr Selby, the proprietor of the island, has lately repaired the weakest part of the walls. The stones appear red with fire, and are wasted away so as to resemble a honeycomb.

> "A solemn, huge, and dark red pile,
> Placed on the margin of the isle."
> MARMION.

The remains of the priory and offices stand on the south side of the monastery, the inside of the walls being built of whinstone, obtained from the rock, which forms a high natural pier on the south side of the island.

The parish church, situated to the west of the monastery, is a plain but spacious Gothic edifice. The pedestal of St Cuthbert's cross, once highly esteemed, is now called the Pelting Stone.

Holy Island is accessible at low water by all kinds of carriages, though there is considerable danger in crossing the sands without a guide. The island, which is a continued plain, is nine miles in circumference, and contains nearly 1020 acres, about one half of which is sand banks. On the north-east side of the island is a tongue of land, about a mile long, and in several places not more than 60 yards wide. The tide may be here seen ebbing on the east, and flowing on the west. Though the soil is rich, yet, before the enclosure of the common in 1792, only 40 acres were in tillage. In 1790, the rent of the whole island was 320*l.*, and in 1797, 926*l.* The town lies on the west side of the island. It appears to have been once much larger, from the names and ruins of the streets. It is principally inhabited by fishermen. The harbour, which is small, lies between the town and the castle, and it is defended by a battery. The castle stands on a lofty whinstone rock on the south-east part of the island, about 60 feet high, and accessible only by a narrow winding pass. It is generally garrisoned by a detachment of invalids.

The parish of Holy Island is likewise called Islandshire, and contains the chapelries of Kyloe, Lowick, Ancooft, and Tweedmouth.

Holy Island was made a bishop's see by King Oswald in 635. In 652, the church was enlarged, but was only made of timber, and thatched; and, in 698, Eadberct, who was bishop for 10 years, covered the roof and walls with sheets of lead. The Danes landed on the island in 793, and a second time in 875, when Bishop Eardulph, along with the inhabitants of the island, took up the body of St Cuthbert, and left the island, with all their relics and sacred utensils. After a pilgrimage of seven years, they at last settled in Chester-le-street.

According to the returns in 1811, there were in Holy Island—

| | |
|---|---|
| Number of inhabited houses | 132 |
| Number of families | 152 |
| Do. employed in agriculture | 67 |
| Do. in trade and manufactures | 47 |
| Total population | 675 |

See Scott's *Marmion*, canto ii. which contains a fine poetical description of Holy Island; the *Beauties of England and Wales*, vol. xii. p. 228; and Hutchinson's *History of Durham*.

HOLYWELL, or Treffynnon, is a town of North Wales, in Flintshire, which derives its name from a remarkably fine spring, which rises at the bottom of the hill just below the town. Holywell is pleasantly situated on the slope of a hill, abounding in lead ore, which rises beautifully above the town. The place is flourishing and well built, and consists of one long street, which is crossed by another, near its centre, of equal goodness.

The church was built in the year 1769. It is a plain neat building, with a square tower at the west end; but though it is furnished with a bell, yet, from its situation below the town, its sound is so inaudible, that it has been found necessary to summon the congregation by a person, who suspends a pretty large one from his neck by a leathern strap, and fixes a cushion upon his knee. This moveable spire walks along, eliciting sounds from the bell, whenever the cushioned knee strikes the instrument. There are other three places of worship in the town, two for Roman Catholics, and one for Protestant dissenters.

The spring called St Winifred's well is reckoned one of the finest in the kingdom. It was found by one experiment to discharge *twenty-one tons* in a minute, and by another 84 hogsheads. In the course of nearly two miles from the source of the spring to its junction with the Chester Channel, its water drives one corn mill, four cotton manufactories, built in 1777, 1785, 1787, and 1790, a copper smelting-house, a brass-house, a foundry, a large copper smithy, a wire mill, a calamine calcinary, &c. The water boils up with great force into a well of a polygonal shape, covered by a colonnaded cupola, having its groined roof loaded with ornaments. It is supposed, but without much reason, to have been built by the Countess of Derby, mother of Henry VII. Near the well is a chapel in the pointed style, which seems to have been built before the time of Richard III. This building belongs to Mr Leo of Llanerch, and has recently been converted into a charity school. A precipitous hill above the church was the site of a fortress belonging to Ranulph the third Earl of Chester. No traces of the building, however, are now to be seen.

The great mining concern, called the Holywell Level, began in 1774, and till lately was an unprofitable concern. The level is carried horizontally for the length of a mile into the hill, and serves both as a drain to the work, and as a canal for the delivery of the ore. Numerous vertical shafts have been cut from this horizontal archway, some of them in pursuit of the mineral veins, and others for the purpose of ventilating the mines. The products obtained from the hill are, 1. Limestone; 2. Chertz or petrosilex, which is ground for the use of the potteries; 3. Lead ore of two kinds, viz. cubic or dice ore, employed in glazing earthen ware, and white or steel-grained ore, containing some silver; 4. Calamine, or ore of zinc; 5. Blende, another ore of zinc, called Black Jack by the miners. The lead ore sometimes brings from thirteen to fifteen pounds per ton, and at other times not more than seven or eight pounds.

An account of the copper and brass manufactures of Holywell has already been given in our article Flintshire, vol. ix. p. 371, to which the reader is referred.

The following is the population abstract of the town of Holywell for 1811:

| | |
|---|---|
| No. of inhabited houses | 1313 |
| No. of families | 1541 |
| Families employed in trade and manufactures | 752 |
| Do. in agriculture | 117 |
| Males | 2925 |
| Females | 3469 |
| Total population, | 6394 |

See *The Beauties of England and Wales*, vol. xvii. p. 708, &c.

HOMANN, John Baptist, an eminent German geographer and mechanic, and a very excellent engraver of maps, was born at Kamlach, a village of Suabia, on the 20th of March, 1663. His parents, who were Catholics, intended that he should embrace the monastic life; but having repaired at an early age to Nuremberg, he became a convert to the tenets of Lutheranism, and devoted himself to the art of engraving, particularly that of maps, which he executed with a degree of correctness and elegance then very uncommon. His first performances of this kind gained him so great a reputation, that he was summoned to Leipsic, where he was employed in engraving the maps to Cellarius' *Orbis Antiquas*. On his return to Nuremberg, he undertook to execute the maps to Scherer's *Atlas Novus*, which was published at Augsburg in 1710. In the year 1702, he established at Nuremberg a manufactory of maps, from which there issued, successively, specimens to the number of two hundred. In 1719, he published an *Atlas methodicus*, for young persons, in eighteen sheets. Under the direction, and with the assistance of another able geographer, Doppelmayer, he also undertook the execution of an astronomical atlas, which appeared, after his death, along with Doppelmayer's Elements of Astronomy, in 1742. Besides maps, he likewise constructed small armillary spheres and pocket globes, and a very curious and ingeniously contrived geographical time-piece.

The scientific and mechanical talents of Homann were deservedly held in high estimation; and his merit was not suffered to languish unrewarded. He was patronised by the Emperor Charles VI. who appointed him his Majesty's geographer; and also by Peter the Great, of Russia. The Royal Society of Berlin admitted him a member of their institution. He died in the year 1724. The manufactory of maps which he established at Nuremberg subsists to this day, and is still conducted under the auspices of his name.

Homann is chiefly known as an excellent engraver of maps; but he likewise possessed a great deal of geographical and astronomical knowledge; and, with an active and enterprising spirit, he combined an inventive genius and uncommon mechanical skill. (z)

HOMBERG, William, an eminent chemist, was born at Batavia, in the Island of Java, on the 8th of January 1652. His father was a Saxon, who had entered into the

Dutch service, and obtained the command of the arsenal of Batavia. Having left this settlement, and gone to Amsterdam, he sent his son to the principal universities in Germany and Italy, where he successively pursued the studies of law, anatomy, botany, astronomy, and chemistry. He was admitted to the bar at Magdeburg in 1674; but having become acquainted with Otto Guericke of that city, the celebrated inventor of the air-pump, he devoted most of his time to the acquisition of the sciences. He now went to the university of Padua, where he studied medicine, anatomy, and botany. After visiting Rome and Bologna, where he discovered the method of making the Bologna stone luminous, he went through France to England, and laboured for some time with our celebrated countryman Mr Boyle. Returning to Holland, he resumed his anatomical studies under De Graaf, and took out his medical degree at Wirtemberg. His passion for travelling, however, prevented him from settling to the practice of medicine. After visiting Baldwin and Kunkel, and exchanging some of his chemical secrets for their methods of preparing phosphorus, he visited the mines of Saxony, Hungary, Bohemia, and Sweden. He next returned through Holland to Paris, where he remained for some time; and when, at the desire of his father, he was about to leave the metropolis, the great Colbert made him such high offers in the name of the King, that he was induced to settle in Paris. He embraced the Catholic religion in 1682, and in the following year he was disinherited by his father for having renounced the faith of his ancestors. In 1685 he again went to Rome, where he practised medicine for some years with great success. On the 4th February 1699, he was admitted a member of the Academy of Sciences, and was allowed the constant use of the laboratory of the Academy. The Duke of Orleans, afterwards Regent of France, erected a magnificent laboratory in 1702, and put it under the charge of Homberg. He allowed him a pension, and in 1704 appointed him his first physician. In 1708, he married Mademoiselle Dodart, the daughter of an eminent medical practitioner; but being naturally of a weak constitution, he lived only a few years, and was carried off by a dysentery, to which he had been liable, on the 24th September 1715. Homberg was not the author of any separate work; but he published no fewer than 102 memoirs in the volumes of the Academy of Sciences, on various subjects, on chemistry, optics, pneumatics, electricity, anatomy, natural history, and the fine arts. See his Eloge in the *Memoirs of the Academy* for 1715. Hist. p. 82.

HOME, Henry, Lord Kames, one of the senators of the College of Justice in Scotland, and an eminent writer both on professional and other subjects, was born in the year 1696. His father, George Home of Kames, was a gentleman of an ancient and honourable family, though of small fortune, in the county of Berwick; his mother was a daughter of Mr Walkinshaw of Barrowfield.

He was educated privately; and, about the year 1712, he was bound by indenture to attend the office or chambers of a writer to the signet in Edinburgh, as a preparatory step to his entering upon the profession of a writer or solicitor before the supreme court. An accidental circumstance, however, afterwards induced him to change his views; and he determined to abandon the more limited occupation of a writer, and qualify himself for the functions of an advocate. With that view, he resolved to supply, by assiduous application, the defects of his imperfect education; and he accordingly resumed the study of the ancient and modern languages; while, at the same time, he endeavoured to acquire a competent knowledge of the sciences. His attention seems to have been particularly directed towards metaphysical investigations, for which, throughout the whole course of his life, he entertained a decided predilection.

In the year 1724, Mr Home was called to the Scottish bar, which was, at that period, graced with the talents of many individuals, who afterwards rose to the first eminence in their profession. Although his mind was abundantly stored with solid learning and legal knowledge, and he possessed, in a high degree, the talents of an ingenious reasoner, Mr Home was not gifted with those shining powers of oratory, which are calculated to bring a young practitioner rapidly into notice. Accordingly, it was not till after the publication of his first work on the law, that he began to enjoy even a moderate share of practice. That work, which consisted of a folio volume of the *Remarkable Decisions of the Court of Session*, from the year 1716 down to the period of its publication, appeared in 1728. Mr Home's manner of pleading was peculiar to himself. He never attempted to speak to the passions, or to captivate his hearers by the graces of oratory; but addressed himself solely to the judgment of his audience; employing a strain of language only a little elevated above that of ordinary discourse, which, even by its familiar tone and style, fixed the attention of the judge, while it excited no suspicion of rhetorical artifice. It would appear, however, that his ability lay more in the devising of ingenious arguments to support his own side of the question, as an opening or leading counsel, than in reply; for which he seems to have wanted that ready command of copious elocution, which is necessary for extemporaneous discussion. There was one peculiarity attending his mode of replying which is worthy of notice. This consisted in a fair concession and abandonment of all the weaker points of his cause. By yielding these at once to his antagonist, he succeeded in creating a favourable impression of his own candour, and a persuasion of the strength of his cause; while, at the same time, he frustrated all attack on those weak parts, which might have given matter of triumph to his opponents, and had a prejudicial influence on the more solid grounds of his plea. But the feature by which Mr Home was principally distinguished as a barrister, consisted in the faculty which he possessed, in a very eminent degree, of striking out new lights upon the most abstruse and intricate doctrines of the law, and of subjecting to the scrutiny of reason those rules and maxims which had become venerable only from long and inveterate usage, having no solid foundation in any just or rational principle.

In 1732, he published a small volume under the title of *Essays on several Subjects in Law, &c.* These subjects had been suggested to him during the course of his employment as a counsel in several important causes; and they contributed greatly to establish the character of the author as a profound and scientific lawyer. From the period of their publication, accordingly, Mr Home appears to have been engaged in most of the causes of importance which occurred in the Court of Session. While occupied with the duties of a laborious profession, however, he did not neglect the pursuits of literature and science, to which he seems to have been at all times ardently devoted; and a considerable portion of his time was also given to the enjoyments of society, in a numerous and respectable circle of acquaintance. He lived in habits of intimacy with many of the first literary and philosophical characters of the age, and frequently corresponded with them on the subjects connected with his favourite pursuits.

In the year 1741, Mr Home married Miss Agatha Drummond, a younger daughter of James Drummond, Esq. of Blair, in the county of Perth, a lady possessed of an excellent understanding, and an enlightened and solid judgment in the conduct of life, with much sweetness of temper, and gentleness of manners. In the course of the same year he published, in two volumes folio, *The Decisions of the Court of Session, from its Institution to the Present Time, abridged and digested under proper Heads, in the form of a Dictionary*,—a work of great labour, and of the highest utility to the profession of the law in Scotland.

During the rebellion in 1745-6, the course of judicial procedure, in the northern part of the kingdom, was interrupted by the disordered state of the country, and the Court of Session did not meet for a period of eleven months. Mr Home employed that interval in various researches connected with the history, laws, and ancient usages of his country, which he afterwards digested into a small treatise, and published in the year 1747, under the title of *Essays upon several Subjects concerning British Antiquities*. These essays, although they contain some curious and important deductions, and exhibit a great deal of ingenious reasoning, are by no means esteemed among the most valuable of the works of their author.

We have already observed that Mr Home's mind was peculiarly turned to metaphysical speculations, for which he found leisure even amidst the pressure of his professional employment. In the year 1751, he published his *Essays on the Principles of Morality and Natural Religion*. This work, in which he endeavoured to place the great principles of morals on a firm and immutable basis, unaccountably drew upon him, from certain quarters, the reproach of scepticism and impiety; and his opinions, particularly on the abstruse question of *free will*, were attacked with great asperity by various writers. Some of these were of so intolerant a spirit, that nothing less could satisfy their zeal, than the interference of ecclesiastical authority, to repress opinions which they conceived to be contrary to the canons of the established church, and subversive even of the fundamental principles of religion. To his opponents, Mr Home made a formal reply, under the title of *Objections against the Essays on Morality and Natural Religion examined*. This controversy attracted the attention of the General Assembly of the Church of Scotland; and a motion was made in the committee for overtures, which was supposed to be indirectly levelled, among others, against the author of the Essays. The motion occasioned a very warm debate, but was finally negatived. However, Mr Anderson, a clergyman, and one of the most zealous of Mr Home's antagonists, resolved not to let the matter rest here. He gave in a petition and complaint to the presbytery of Edinburgh against the printer and publisher of the *Essays on the Principles of Morality and Natural Religion*, requiring that the presbytery should summon them to appear before them, and declare the name of the author of that work, in order that he might be subjected to ecclesiastical censure. The persons complained against appeared by their counsel, and gave in formal defences; but Mr Anderson died during the course of the proceedings. The defendants, however, waving all objection to the want of a prosecutor, consented that the court should give judgment on the merits of the case; which, after undergoing some discussion, terminated in the rejection of the complaint.

In the month of February 1752, Mr Home was appointed one of the Judges of the Court of Session, by the title of Lord Kames. His promotion gave general satisfaction to the country, as his abilities and knowledge of the laws, no less than his integrity and moral virtues, had raised him high in the public esteem. To the discharge of his duties, as a Judge of the Supreme Civil Court, he brought an acute understanding, an ardent feeling of justice, and a perfect acquaintance with the laws of his country; which, amidst the variety of pursuits in which his comprehensive mind had been engaged, had always received the principal share of his attention. His judgments, which were always formed with deliberation, had deservedly the greatest weight with the Court, especially on all questions of recondite jurisprudence. Towards the bar he uniformly conducted himself with a proper courtesy and respect; listening to the arguments of the senior counsel, who pleaded before him, with patient attention, and animating the diffidence of the younger barristers by kind indulgence and urbanity of demeanour. In his character he occasionally displayed something of the humourist; and, even on the bench, he could not always repress his constitutional vivacity, which sometimes broke out in amusing sallies, when the subject of discussion led to a ludicrous train of thought, or when a happy repartee was suggested by the wit of the counsel.

A society had been instituted in Edinburgh, in the year 1731, for the advancement of medical knowledge, the plan of which was afterwards extended, at the suggestion of the celebrated Maclaurin, to subjects of philosophy and literature. It was now known by the title of *The Society for Improving Arts and Sciences*, but more generally by that of *The Philosophical Society of Edinburgh*. At what period Mr Home first became a member is uncertain; but he appears to have been elected its president about the beginning of the year 1769; and in the volume of the *Transactions* of that learned body, published in 1771, there are three papers of his writing, viz. *On the Laws of Motion; On the Advantages of Shallow Ploughing;* and *On Evaporation*. They exhibit the same ingenuity which is conspicuous in all his productions; but the papers on physical subjects are not built on sound philosophical principles.

In the year 1755, Lord Kames was appointed a member of the *Board of Trustees for the Encouragement of the Fisheries, Arts, and Manufactures of Scotland;* and about the same period, he was chosen one of the commissioners for the management of the forfeited estates annexed to the crown, of which the rents were destined to be applied to the improvement of the Highlands and Islands of Scotland. In the discharge of these important trusts, he was a zealous and faithful servant of the public. He regularly attended the stated meetings of these boards, generally officiating as chairman, and taking a most active concern in all their proceedings. In the midst of his professional and literary occupations, he was at all times easy of access to the meanest individual who had any application to make; and was ready not only to advise, but even to assist the ignorant and needy suitor in bringing his claims fairly into view.

In 1757, he published *The Statute Law of Scotland Abridged, with Historical Notes*, and two years afterwards he gave to the world his *Historical Law Tracts*, each in one volume 8vo. The latter work has undergone several editions, and stands deservedly high in the estimation of the public. It is one of the few works which unite law with philosophy and the study of human nature; and it has accordingly received the praise, not only of juridical authors, but of the writers on politics and morals, both of our own and of foreign countries. In 1760, appeared his *Principles of Equity*, in which he traces historically the origin of the courts of equity in each of the united kingdoms, and endeavours to ascertain those general rules by which a court of equity ought to be governed. The active mind of Lord Kames, however, did not confine its efforts to those studies and researches which were more intimately connected with his profession, but exerted its powers in various pursuits of a generally interesting nature. In the course of the education of his own children, he was led to the composition of an elementary work, suited to the minds of young persons, and calculated at once to improve the understanding, and to cultivate just notions of morality. This little work he published in 1761, in a small volume, under the title of *Introduction to the Art of Thinking*. It is divided into two parts; the former containing a series of moral and prudential maxims, and the latter a regular illustration of those maxims by stories taken either from real history, or fictitious narratives.

It appears from the letters of some of Lord Kames's correspondents, that he had for several years meditated an extensive work on the principles of criticism. This design he afterwards carried into execution by the publication of his *Elements of Criticism*, which first appeared in the year 1762, in three volumes 8vo. In this elaborate work, it was the object of the author to subject the impressions made on the mind by the productions of the fine arts to the standard of reason, by showing, that what is generally called taste is by no means arbitrary, but depends on certain principles or laws of the human constitution; and that a good taste consists in the consonance of our feelings with those laws.

From the period of the publication of the last mentioned work, Lord Kames appears to have devoted himself for a few years exclusively to his professional occupations. On the 15th of April 1763, he was appointed one of the Lords of Justiciary, that is, one of the Judges of the supreme criminal tribunal in Scotland. The duties of that situation he continued to discharge, to the end of his life, with equal diligence and ability. In the year 1766, he received a very large addition to his income by the succession to the estate of Blair-Drummond, which devolved on his wife by the death of her brother. The seasons of vacation were now spent at Blair-Drummond, where he began to execute a variety of agricultural improvements on an extended scale, which, while they set a great example for the imitation of the neighbouring landholders, have proved of the most solid and permanent benefit to the proprietor and his heirs. Among these plans of improvement was one of a nature so extraordinary, as to be generally regarded at first as chimerical, but which ultimately succeeded far beyond the most sanguine views of its contriver. We allude to the operations commenced and carried on by his lordship on the moss of Kincardine; of which we shall have occasion to take some notice in the article MOSS in this work. With these substantial improvements he combined many plans of embellishment, suggested by those great features of natural beauty which the surrounding scenery exhibits.

Towards the end of the year 1765, Lord Kames published a small pamphlet on the progress of the flax husbandry in Scotland, of which the principal object was, to show the expediency of encouraging the culture of flax of the native growth of the country. At the same time his lordship, availing himself of a most extensive acquaintance with the principal landholders in Scotland, endeavoured, with a laudable zeal, to stimulate their exertions in diffusing a spirit of industry among their cottagers and dependents, by the introduction of such species of domestic manufactures, suited to both sexes, as, without any considerable expence on the part of the proprietors, would ameliorate the condition, and multiply the comforts, of the lower orders, and thus lay the solid foundation of an increase of their own revenues. Among those patriotic plans of national improvement, in which Lord Kames, as a member of the board of trustess for the encouragement of arts, took a most active concern, was the great and useful project of a navigable canal between the rivers Forth and Clyde, which was begun in 1768, and from which, since its completion, the internal commerce of the country has derived the most essential benefit.

In the year 1766, Lord Kames published his *Remarkable Decisions of the Court of Session, from 1730 to 1752*. The reports contained in this volume consist of 130 cases, comprehending the most important causes which had occurred in the course of his own practice while at the bar.

For many years Lord Kames had been employed, during his leisure hours, in collecting materials for a *History of Man*. The design of this great work, however, as at first conceived, was found to be too vast; and he afterwards wisely determined to confine his plan within narrower limits. The work was at length published in the year 1774, under the title of *Sketches of the History of Man*, in two volumes 4to. Although published in the form of separate essays or dissertations, it is digested with a considerable degree of systematic regularity, and is valuable, not only from the great variety of important objects which it embraces, but on account of the genius and ability displayed in their discussion.

In the year 1776, he published his *Gentleman Farmer*; a work of great utility at the period of its publication, and which affords a singular specimen of the undiminished vigour of his mind at the advanced age of eighty. Even at this late period of his life, his constitution appeared to have suffered nothing from the attacks of old age. There was yet no sensible decay of his mental powers; and, what is still more extraordinary, he possessed the same flow of animal spirits, the same gaiety and vivacity, and the same ardour in the pursuit of knowledge, for which he had been distinguished in his early years.

In 1777, he published his *Elucidations respecting the Common and Statute Law of Scotland*, in one volume 8vo; and in 1780, his *Select Decisions of the Court of Session*, in one volume folio. The latter publication contains 264 reports of the most important cases decided by the court, between the years 1752 and 1768, and forms a supplement to the cases formerly published under the title of *Remarkable Decisions*. The last work of Lord Kames was his *Loose Hints on Education*, published at Edinburgh in the year 1781, when the author was in the 85th year of his age.

Although apparently by no means of a robust frame of body, Lord Kames had hitherto enjoyed an uncommon share of good health; but in the beginning of the year 1782, when he had nearly completed his 86th year, he was seized with a disorder of the bowels, which, being attended with no pain, gave him, for a considerable time, very little apprehension. Finding, however, after some months, that the disease had not yielded to medicine or regimen, he began to regard it as likely to terminate fatally. During the summer term of the year above mentioned, he regularly attended to his official duty in the courts of session and justiciary, and at the end of the term, he went as usual, with his family, to Blair-Drummond. He also attended the autumn circuit; but, on his return, his strength decreased daily, although the serenity and cheerfulness of his temper remained unabated. He left Blair-Drummond in the beginning of November, and continued, for some little time, to attend the meetings of the court of session; but he soon became sensible that his strength was not equal to the effort. On the last day of his attendance, he took a separate and affectionate farewell of each of his brethren. He survived that period only about eight days, and died on the 27th of December 1782, in the 87th year of his age.

In his person, Lord Kames was very tall, and of a thin and slender form. His countenance was animated, and strongly marked with the features of intelligence and benignity. At every period of his life he had a high relish for the pleasures of society; and it was usual for small and select parties to meet at his house in the evenings, during the winter and summer sessions, without invitation. In these parties, the discussion of literary topics was agreeably blended with innocent sallies of mirth and pleasantry; and the graver conversation of a Smith, a Blair, and a Fergusson, was relieved or enlightened by the native wit and polished manners of a Cullen, or the sprightly fancy and whimsical eccentricity of a Boswell. The artless and ingenuous disposition of Lord Kames led him, at all times, to express his feelings and opinions without reserve or disguise; and this propensity, combined with a certain humorous playfulness of manner, might frequently convey to strangers the unfavourable idea of a bluntness and levity, derogatory from that dignity and attention to decorum, which one so naturally associates with talents and eminence. But this impression was soon effaced by that vigour of intellect, that frankness, integrity, and candour, which his conversation never failed to display. He engaged with interest in the discussion of almost every topic that occurred, whether of ordinary life, literature, or science; and, although naturally communicative, he was always as ready to listen to the opinions of others as to deliver his own sentiments. To the introduction of political subjects, however, in common conversation, he had a strong dislike; and when the conversation happened to take that turn, he either took no part in it, or endeavoured to divert it by some timely pleasantry, or guide it with address into a different channel.

To the distinguishing features of Lord Kames' character, as a laywer, a judge, an author, and a man, we have had frequent occasion to allude in the course of the preceding narrative. He certainly contributed, more than any other individual, to explain, illustrate, and define the origin, progress, and character of the laws and institutions of his country; his unwearied attention to agriculture and internal improvement, and his zealous encouragement of every useful project, bear sufficient testimony to his public spirit; and, however widely he might occasionally err in his speculations on subjects of strict science, his many and valuable publications, on literary and philosophical subjects, will prove a lasting monument of his genius and industry. See Lord Woodhouselee's *Memoirs of the Life and Writings of Lord Kames*. The writer of this article has also been favoured with the perusal of the MSS. of John Ramsay, Esq. of Ochtertyre, in which there are many interesting particulars, illustrative of the characters of Lord Kames and other individuals, whose talents contributed to elevate the literary reputation of their native country during the eighteenth century (*z*)

HOME, John, a clergyman of the church of Scotland, but best known to the public as author of one of the most classical tragedies in the English language, was a descendant of one of the ancestors of the Earl of Home. It was once reported, that he had some pretensions to the title of the Earl of Dunbar, but upon what grounds we have never been able to learn. His father was clerk, or, as it might be termed in England, recorder of the town of Leith.* Our poet was born at Leith in September 1722. He received the elementary part of his education at the parish-school of his native place; after which he went to the university of Edinburgh, and there went through the customary course of the languages and philosophy, with the reputation of a respectable and diligent student. At the university he was the intimate companion of several of those eminent men, who, like himself, afterwards contributed so highly to raise the literary reputation of Scotland about the middle of the eighteenth century. Among these were, Drs Robertson and Blair, and Professor Adam Ferguson. The circle of his intimate friendship afterwards included David Hume and Lord Kames. Being educated for the church, he had passed through the divinity-hall, and was about to enter upon the duties of the clerical profession, when he was suddenly called to forsake his studies by the rebellion that broke out in Scotland in the year 1745. On the approach of the rebels, the citizens of Edinburgh assembled, and formed themselves into an association for the support of their sovereign, and the defence of the city; and in this association Mr Home was appointed to be lieutenant of a company of volunteers. In the first crisis of alarm, it became a question among those who had taken up arms, whether they should wait for the approach of the rebels within their walls, or march out to meet them, and act with the king's army. Mr Home, with the more active spirits, was in favour of the latter plan; and while the bulk of the volunteers remained in the Scottish capital, he was one of a much smaller number, who solicited and obtained permission to follow the army of Hawley into the field. At the unfortunate battle of Falkirk, he was taken prisoner by a party of Prince Charles's troops, and was for some time confined a prisoner in the castle of Downe. From thence, however, he soon afterwards contrived to effect his escape; and public tranquillity having been restored by the victory of Culloden, he resumed his studies, and was licensed to preach. In the same year, 1746, he was presented to the living of Atholstaneford, in the county of East Lothian. It gives a poetical interest to the name of this parish, that it had successively for clergymen two poets of respectable names, Mr Home having succeeded in that living to Blair, the author of *The Grave*. In this retired situation, however, we cannot suppose the dramatic muse of Mr Home to have found herself so congenially situated as the more sombrous genius of his predecessor. Accustomed to the sweets of literary society, and elegant in his pursuits, he probably felt the life and duties of a country parish priest far from being delightful. To a mind teeming with dramatic conceptions, the offices of visiting, catechising, and spiritual rebuking, must have been somewhat irksome. He appears, however, to have sometimes taken the recreation of a visit to England; and on one of those occasions he met with Collins the poet, whose mind immediately felt a pleasing congeniality with that of Home. In his *Ode on the Superstitions of the Highlands*, we have almost the only record that Collins has left of his personal friendship, when he says,

> Go not regardless, while these numbers boast
> My short-liv'd bliss; forget my social name,
> But think far off, how, on the southern coast,
> I met thy friendship with an equal flame.

The tragedy of Douglas, though the first play of Mr Home's that was brought upon the stage, was not the first of his composition. He had before written *Agis*, a tragedy, of which we shall have occasion to speak hereafter. The plot of the tragedy of Douglas, as few will probably need to be told, was suggested by the ancient ballad of Gill or Child Morrice. Hearing a part of that beautiful old

* It should be observed, however, that the English recorder's office is of higher dignity than that of the Scottish clerk, who does not sit, like the former, on capital cases.

song sung by a lady one evening after a supper party in Edinburgh, Mr Home remarked, that he thought it contained the germs of a tragedy; and very soon made good his opinion, by commencing to dramatise the story. Douglas made its first appearance on the Edinburgh theatre, which was then in no unflourishing condition, in the year 1756. When the managers received the MS. they readily accepted it, put it into rehearsal, and prepared for giving it a magnificent representation. The transaction, however, coming to the knowledge of the elders of the kirk, they, in their great zeal, first remonstrated with the author on the heinous sin he was committing. Failing in this remonstrance, they endeavoured to terrify the performers from representing it; but with no better success. Author and actors remained equally incorrigible, and nothing remained for the incensed elders to do, but threaten to expel, and for ever disqualify for the ministry, not only their disobedient poet, but even such of his clerical friends as had been wicked enough to go to see his piece performed at the theatre. In pamphlets and advertisements, they thundered their anathemas against those implements of Satan, the actors, who had led aside, or at least abetted in his wandering, the lost sheep of their flock. The presbytery of Edinburgh published an admonition and exhortation against stage-plays, which was ordered to be read in all the pulpits within their bounds, on a Sunday appointed. In this proclamation, there was no mention of Mr Home or his play, though it was evidently against him that this spiritual artillery of obsolete laws and fanatical prejudices were levelled. To avoid a formal expulsion from the church, Mr Home, in 1757, resigned his living, and with it the ecclesiastical profession, and wore for ever after a lay habit. Similar as the Puritans of England and the Scottish Calvinists might have been half a century before, this ejection of an amiable and accomplished clergyman from the Scottish Kirk, for the crime of writing a tragedy, which did honour to the genius of the nation, excited among the more liberal part of the Scotch, and much more generally in England, a sense of indignation at the injustice, and ridicule at the absurdity of the procedure. That leaven of bigotry happily is now far extinct; we believe the last mark of it is to be found in the article Home, in the Biographical Dictionary of Mr A. Chalmers, the writer of which article gravely denies the treatment of Mr Home to have been unjust, since the constitutional laws of the Kirk of Scotland denounced stage-plays. If the writer of this luminous opinion were at present flourishing in Spain, he might argue with equal justice in favour of the burning of heretics, on the grounds of the ancient laws of the Catholic Church—as if an enlightened age were for ever bound to follow the dead letter of primitive barbarism. Happily, in Protestant communities, such an example of clerical hostility to the cause of literature stands alone: for parallels to it we must go back to times of Paganism and Popery. It may remind us of the persecution of Æschylus, in consequence of the clamour of the Athenian priests, or of the influence of the monks in Spain, when neither the patronage even of Philip IV. nor the orthodoxy of Lope de Vega's works, were sufficient to screen him from the personal virulence of the ecclesiastics. At no very distant period, indeed, during an epidemical disorder, the inhabitants of Seville renounced the amusement of the theatre, as the surest mode of averting Divine vengeance. To return, however, to our author. His tragedy of Douglas was extolled, on its first appearance, by the literary circles of the North, in terms that were perhaps rather unqualified. David Hume gave it as his opinion, that it was one of the most interesting and pathetic pieces ever exhibited on any theatre; he even gave it a preference to the *Merope* of Maffei, and that of Voltaire. The rest of the philosopher's panegyric on our author, in which he alluded to Shakspeare, may, for the credit of his taste, be left unquoted. The poet Gray, in one of his letters to a friend, renders an homage to the play of Douglas, that is perhaps not much lessened by his fastidious allusion to its defects. "I am greatly struck," he says, "with the tragedy of Douglas, though it has infinite faults. The author seems to me to have retrieved the true language of the stage, which had been lost for these hundred years; and there is one scene between Matilda and the old peasant, that strikes me blind to all its defects." Jackson, in his *History of the Scottish Stage*, informs us, that when this tragedy was originally produced in Edinburgh, the title of the heroine was Lady Barnard. The alteration to Lady Randolph was made on its being transplanted to London. Its success at the Edinburgh theatre induced Mr Home to offer it to the London managers, where, notwithstanding its rising celebrity, and all the influence used in its favour, it was refused by Mr Garrick. Mr Rich, however, accepted it, and it was acted for the first time at Covent Garden, March 14, 1757, with some applause, but by no means such as indicated the future celebrity which it was to obtain.

On resigning his living, Mr Home repaired to England, where the munificent patronage and unremitting friendship of the Earl of Bute made him ample amends for the abandonment of his profession. Lord Bute having become first minister on the accession of his present majesty, appointed him, in March 1763, a commissioner for sick and wounded seamen, and for the exchange of prisoners of war; and in the next month of the same year, he was nominated conservator of the Scotch privileges at Campvere in Zealand. From the period of the exhibition of Douglas, down to the year 1778, Mr Home brought five other tragedies before the public. Of these, *Agis*, as has been already mentioned, had been composed before that of Douglas. Mr Garrick had formerly refused this piece as well as Douglas; but as it was now considerably altered, and the author's reputation established, the manager brought it forward at Drury Lane in 1758. The play is founded on a story in Spartan history. It is pretended that the author has kept up in the character of Agis a continued allusion to the misfortunes of Charles the First; and the figurative retrospect of the conduct of the Scots towards their sovereign was charitably ascribed, by the conjectures of English criticism, to the author's vindictive feelings towards his countrymen. The allusion was in all probability either casual or imaginary—the imputed motive is inconsistent with all that is known of the character of Home. Agis was certainly heard with impartiality, and even with that partial disposition which the author of Douglas had a right to expect. It had the additional advantage of good acting, and of two solemn musical processions. But the intrinsic merit of the piece could not secure to it a lasting popularity. On perusing it, the poet Gray writes this melancholy sentence to Dr Warton, "I cry to think that it should be by the author of Douglas. Why, it is all modern Greek. The story is an antique statue, painted white and red, frigid, and dressed in a negligée, made by a mantuamaker of Yorkshire." Mr Home's third tragedy was the *Siege of Aquileia*. It was acted with indifferent success at Druly Lane, in 1760. From the title, we should expect that the author would have adhered, with general fidelity, to the circumstances, as they are recorded in history, of the defence of that city by the legions of Gordianus, against the gigantic tyrant Maximin; but, in reality, the incidents of the play agree much nearer with the history of the Siege of Berwick, defended by Seton against the arms of Edward III.; and it was conjectured, with some appearance of plausibility, that Mr Home had received his first hint from the latter story; but disliking to bring Edward the Third before an English audience, in the light of a brutal tyrant, in which the siege of Berwick too strongly exhibited him, he thought proper to preserve the circumstances, only under the disguise of more ancient names. This play is regular in its structure, and the language in some passages is fine; but, on the whole, the incidents are too few, the distress too unvaried, and the catastrophe too clearly anticipated. Mr Home's muse cannot be said to have prospered beyond the time when she was rich enough to lend images to Ossian. The shrieking of the spirit of the waters was an admired expression in the description of the tempestuous night in Douglas, which seems to anticipate much of the spiritual imagery of Macpherson. Gray the poet puts a query in one of his letters, whether Home borrowed this from Macpherson, or Macpherson from Home. Without pretending to enter on the wider question of Ossian's authenticity, we shall only notice, that the play of Douglas appeared some years earlier than the fragments ascribed to Ossian. The latter, as we have seen, was acted in 1757; Macpherson did not come before the world till 1760. By the *Fatal Discovery*, Mr Home's next tragedy, it would seem that our author was willing to be reimbursed for whatever hints of fancy he had lent to the Gaelic muse, and accordingly he supplied himself in this piece with much of the famed phraseology of Fingal. But whatever might be the real demerits of the *Fatal Discovery*, the London public seems not to have been disposed to receive it with an equitable judgment. To such a height, we are told in the *Biographia Dramatica*, had party prejudice risen against Mr Home, on account of his enjoying the patronage of the Earl of Bute, that it was found necessary to conceal the author's name during the first nights of its representation; and, after the twelfth night, Mr Garrick was threatened with having his house burnt down, if he continued it: an injunction with which the managers thought it advisable to comply. *Alonzo*, Mr Home's next tragedy, was more successful than any other of his productions, *Douglas* alone excepted. It had a considerable run on its first appearance, and added much to the rising reputation of Barry as an actor; but it never obtained the rank of what is called a stock play, nor was afterwards performed, except at provincial theatres. The language of the tragedy of *Alonzo* possesses considerable force and purity, though the cadence of its versification is, like all the blank verse of that period, too little varied in the pauses, and monotonously concludes the rhythm with every line. The story is also romantic and lucidly brought out, but it is rather too much like an echo of *Douglas*. Ormisinda brings us back Lady Randolph. She is not indeed a widow; but has been forsaken for eighteen years by the husband of her early love, who had groundlessly suspected her virtue. They had married unknown to her father, and their meetings were in a solitary place; where a confidential servant, in order to give the semblance of protection to Ormisinda, assumed the plume and vesture of a brother. Deceived by this appearance, Alonzo had abandoned her, wandered in foreign countries, and returned only in disguise to fight with the Moors in behalf of Spain. In his absence Ormisinda has secretly reared his son at a distance from her, and unconscious of his birth. Like Douglas, he bursts from obscurity into martial reputation, and offers to become her champion without knowing that she is his parent. Alonzo conquers the Moorish champion, throws off his disguise, declares his marriage with her from whom he has been eighteen years separated, and, in a scene which is pretty striking, demands, as the reward of his services, that the king shall sentence her, his own daughter, to die. The conscious innocence of Ormisinda,—the agony of her wrongs,—the bursts of her affection towards Alonzo,—and her maternal feelings at the sight of her boy rushing to combat with his unknown father,—compose a strong situation of terror and pity; and the moment when she throws herself between their swords, is one of rivetting interest. It may be questioned, however, if the effect would not have been much better, had the termination been fortunate. In plots where a happy denouement would not be merely satisfactory, but joyous and exultingly triumphant, the policy of killing the tragic victims is very doubtful. Ormisinda was not like Lady Randolph, who, though her son was restored, had only a second and apparently not a distractedly beloved lord to be reconciled with; she had all the pledges of filial, maternal, and conjugal love to redeem, as well as honour, and the inheritance of a throne; and the catastrophe that severs her from all those blessings, seems to depend more on the tragical resolution of the poet, than on that overawing *fatality which gives dignity to dramatic slaughter.*

*Alfred*, our author's last tragedy, was acted in Covent Garden in 1778, but was only performed for three nights.

It is impossible to follow this detail of Mr Home's dramatic career, without a melancholy reflection on the power of genius itself being included in the sentence of mutability which is passed on all earthly blessings. With *Alfred* he took his leave of the stage, and retired to Scotland, where he continued to reside during the greater part of his remaining life. In 1778, when the late Duke of Buccleugh raised a regiment, under the name of Fencibles, Mr Home received a captain's commission, which he held till the peace. A few years before his death, he published the *History of the Rebellion in Scotland in* 1745: a work of which great expectations were formed; but whether he delayed it until his powers of mind had lost their vigour, for he was now seventy-eight, or did not feel himself at liberty to use all his materials, the public was not satisfied. For a considerable time before his death his mental faculties were impaired, and his health was much affected by a dangerous fall from his horse. He died at Merchiston house, on the 4th September, 1808, at the advanced age of eighty-five. (*n*)

HOMER, (the Grecian poet.) Without leaning to the faith of those who have denied the existence of Homer, we cannot avoid noticing the remarkable circumstance of his existence having been called in question. Both learning and ingenuity have been employed in attempting to prove, that neither the Iliad nor the Odyssey were the production of a single genius, but composed by the rhapsodists, who recited those poems in detached parts; and that the name of Homer, which in the Eolian dialect of Greek, signifies "blind," was either applied to some personage wholly fanciful, or, by way of eminence, to some strolling declaimer of the Iliad, who may have executed parts of the poem, but cannot be supposed to be the author of the whole. It may seem a paradoxical way of annihilating an individual to multiply his existence; but yet, by proving a diversity of Homers, if such a thing could be proved, our homage to the single author of the Iliad would be shaken, and the reputation of a sacred name would fall with its loss of unity. Annius of Viterba pretends to give the authority of Archilochus, an author to whom he ascribes the most remote antiquity, for the existence of eight different authors of the Iliad, among whom are gravely registered Apelles the painter, and Phidias the statuary. But for the comfort of those who may feel alarmed at the threatened dismemberment of the Homeric existence, it must be mentioned, that this Annius of Viterba, who was a Dominican friar, and master of the sacred palace under Pope Alexander VI., was an impostor, who had not even skill to palm upon the world the MS. page of this ancient Archilochus, which he pretended to find, and stands upon record as one of the most impudent and clearly convicted of literary forgers. The book, which he called the Genuine Remains of Sanconiathon Manetho, &c. brought him the same species of reputation that accrued to the younger Ireland, from his Shakespeare MSS., or to Mr John Pinkerton from his execrable additions to Hardyknute.

By far the most formidable opponent of the unity of the author of the Iliad is the learned German Professor Wolff, who supposes Homer to be either an imaginary being, or, at most, one of the earliest of the rhapsodists. In the works which he prefixed to the works and remains of Homer and the Homerides, there are several false inferences, deduced from admissible facts, brought forward with a boldness that might indeed have been expected from a writer who arrogantly pronounced his work to be above all critical objections, and who predicted, that no Grecian scholar should attack it with impunity.

In opposition to all scepticism regarding Homer, every candid mind will agree, that the settled and prevailing belief of antiquity is not to be made light of in such a question. It is true that Homer's birth-place, as well as his age, are disputed, but such controversies are not apt to be started about imaginary beings. It is unreasonable to say, that a poet so illustrious as Homer, if he had been the acknowledged author of the Iliad, must have been known to his own contemporaries. Only a few scattered anecdotes of Shakespeare himself have reached the present day. In an age, such as the probable age of Homer, had a man of genius a better chance of finding contemporary biographers? When Massinger was buried, all that could be told of him, in the inscription upon his tomb, was, "Here lies Philip Massinger, a stranger." To adduce all the proofs that could be given of great poets being neglected by their contemporaries, would unhappily be to write the history of the greater part of them. In forming our opinion of narratives that exceed the accustomed phenomena of nature, we cannot be sufficiently cautious of making the creed of a past age the standard of our own belief. But tradition that is free from the marvellous is fairly entitled to confidence, and the tradition which assigns a single author to the Iliad, a tradition which Lycurgus and Aristotle believed, has surely nothing in it so incredible, as that a work, so remarkable for simplicity of design, should have been the work of fortuitous and successive composers. Great works of science may, indeed, be thus built up by accumulation, but great poems and pictures are not usually constructed by a multiplicity of artists. Nor, if the Iliad had been the work of successive rhapsodists, is it easy to conceive by what poetical effort of modesty those authors suppressed their respective rights upon the gratitude and admiration of posterity.

We must distinguish, however, between the credit that is due to the general tradition of Homer having been a wandering reciter of his own poetry, and the more specific facts that are pretended to be given as the history of his life. The most ancient work of this kind is the life of Homer attributed to Herodotus. Whether this be the genuine production of Herodotus, we are far from pretending to decide. The opinion of Professor Heyne, which was apt to be deliberately formed, is unfavourable to its authenticity, as he pronounces it impossible to ascertain either the age or country of Homer. The learned Vossius also rejected its authority, on the ground that no writer makes mention of the work, previous to Stephen of Byzantium and Suidas. This argument, though it comes from a great name, is certainly not quite conclusive. By far the most important objection to it is, the different calculations of chronology exhibited in Herodotus the historian of Greece, and the Herodotus to whom this life of Homer is assigned. The former, in his Euterpe, speaks of himself as posterior to Homer by only 400 years; while the latter computes a period of 622 years, and the expedition of Xerxes across the Hellespont, a difference of nearly 200 years. On this account, Eustathius wishes to assign the life of Homer to another Herodotus, surnamed Olophyscius, instead of the historian of Halicarnassus. Admitting the above objections in their full force, it cannot be affirmed that they amount to a demonstration of the biography itself being either spurious, or fraught with internal marks of falsehood. On the contrary, the birth-place, which it gives to the author of the Iliad, corresponds with an inference most plausibly drawn by an enlightened traveller from the poet's descriptions of external nature, that he paints them with the very circumstances that would occur to a native of Chios or Smyrna. If Homer was born at the latter place, the vicinity of Herodotus's birth-place would naturally make him anxious to collect every tradition respecting him; and in the wandering life and disastrous voyages which those traditions describe, there is every thing which the state of society in such an age renders probable. It cannot well be doubted that the author of the Iliad and the Odyssey was a traveller, as they are both the evident offspring of a mind which had contemplated nature and human life in a full variety of aspect and manners, and of one who had felt much from the opposite dispositions of good and bad in his own species; who, according to the circumstances then existing in society, had

> "Walked in every path of human life,
> Felt all its passions, and to all mankind
> Doth now, will ever, that experience yield,
> Which his own genius only could acquire."
>
> AKENSIDE, *Inscription for the Bust of Shakespeare.*

Our ingenious countryman Wood* had a higher opinion of the authority of the work in question; and although some allowance may be made for the gratification of the traveller, in finding that theory respecting Homer's history, which he had himself so plausibly deduced from his landscapes and similes, confirmed by a work ascribed to so venerable a name as that of Herodotus, yet Wood's remarks are worth attending to: "It may be here requisite," (he says, p. 189, *Essay on Homer*,) "that I take some notice of the ancient life of Homer, handed down to us, and ascribed to Herodotus. The life of Homer is supposed by several not to be the genuine production of that historian. As it is impossible to imagine a collection of circumstances which have less the appearance of fiction, I do not see why we should not suppose that this was the last and most probable account that the historian could get. As for the observation that they belong to the lowest sphere of life, I fear it is suggested by modern distinctions of rank unknown in those times. When we are told, by way of depreciating this written life, that it is conducted with the spirit of a grammarian; that there is nothing in it above the life which a grammarian might lead himself; nay, that it is such a one as they commonly do lead, the highest stage of [illegible]s to be master of a school; we are treated with objections which arise much more out of a knowledge of modern than ancient times. The character of a grammarian was unknown, not only to Homer, but to Herodotus;

* *Essay on Homer.*

and when it did appear, was much more respectable than of late, when, by an easy transition, it is connected with the name of schoolmaster, as in the present case, and conveys very false ideas of the state of knowledge and learning. Of the same sort is the stricture upon the extempore verses of this treatise, which, far from being an argument against it, I take to be the most genuine mark of the age to which it pretends. When in a written composition, the distinction of prose and verse was of a short standing, what we here call extempore verses, which are so often interspersed in the works of Herodotus, and the oldest of the Greek writers, I suppose to have been quotations from that period of knowledge previous to the common use of writing, when prose was confined to conversations, and all compositions were in metre, that they might be more easily remembered." In this life of Homer, attributed to Herodotus, the name of the poet's mother is said to have been Critheis, a native of Smyrna: he was the offspring of illegitimate love.

> "No sickly fruit of faint compliance he,
> Stampt in the mint of Nature's ecstacy."
> Savage.

Critheis had been left an orphan. Her tutor, whose name was Cleanax, having disgraced her for her frailty, she was obliged to fly from her native place, and after wandering for some time, arrived at the banks of the river Meles. There she was delivered of the infant, who, from the place of his birth, was called Melesigenes, a name which he bore till it was changed to Homer after his blindness. Phemius, an inhabitant of Smyrna, who taught music, took the unfortunate mother into his house, married her, and adopted the child Melesigenes. The youth for some time assisted them in the school of music, but after their death was seized with a desire of seeing foreign countries, and embarked with a Phenician shipmaster. Among other places, he arrived at Ithaca, where he learnt the adventures of Ulysses; but his stay was unfortunately prolonged till he was struck with ophthalmia, which the ignorance of a pretender to the healing art soon made incurable. Already he had been a poet, and he now consoled his blindness by composing the Iliad. With this treasure in his memory, he wandered from place to place, and subsisted by reciting it. Universal tradition thus exhibits to us the greatest genius of antiquity as wandering about in blindness, and supported by the spontaneous kindness of those whom he visited. But the idea of such mendicity must not be confounded with the repulsive and squalid associations which the word beggary brings to the mind in our own artificial state of society, when disgrace covers the supplicant, and when the feeling of compassion carries contempt, and not kindness, along with it. In simple times, the traveller went abroad, and sought protection and food with the assurance, that, whenever he saw the human countenance, he should meet with the natural charity of the human heart. He made his way with confidence, for hospitality was the virtue and the point of honour of primeval society. A picture of such hospitality is given in the Odyssey, when Mentor and Telemachus arrive at the dominions of Nestor. The King, who knows nothing of the visitants, invites them to the royal table, and, not until he has feasted them, puts the question, "*Strangers, what are you?*" But Homer did not visit foreign countries with merely the common claims to hospitality, religiously respected as those claims were sure to be. He travelled in the character of bard and reciter, of which an image was renewed in modern Europe among the minstrels and the troubadours. Of the latter description of poets, we know that many held an honourable place at the most splendid courts, were the inmates of palaces, and the suitors of noble dames. The Greek itinerant bard, in times when books and writing were unknown, must have been a character not coldly respected as a stranger, but esteemed and beloved for his powers of entertainment. Poetry was then not only the ornament of sentiment and beautiful fiction, but embraced all that was the mental amusement, and all that could be called the knowledge of mankind. It taught them what they believed to be their history; celebrated their mythology; gave them romantic conceptions of the past and the present world; and gave additional pleasure to the heart, by the charm which it afforded to the ear. Such was the profession of the ancient poet; but which, nevertheless, though immeasurably removed above the contempt of contemporary society, must have been exposed to many incidental calamities. The very virtue of hospitality arose out of a state of society, that rendered travelling and navigation fatiguing and perilous. When the poet could only recite his works, the honours and caresses due to genius and originality alone might often be lavished on the least inspired of the profession, who drew their stores of entertainment from a memory tenacious of the compositions of others; and hospitable as the times might be, the general partiality of the undistinguishing multitude for impudence and flattery might often favour the mere pretenders to poetry, while the lofty mind of the true poet could not stoop to canvass for popularity. In the life of Homer, already mentioned, we find the prince of poets encountering adversity in many shapes. At several places it tells us of his applying to the rulers of the state for maintenance at the public expence, and promising to immortalize their history by his compositions. If the author of the life, whoever he was, contrived those traditions, it is singular that he has told by anticipation a story so nearly resembling the fortunes of Tasso and of Dryden. Among the Phocians it is also related, that a perfidious brother poet, Thestorides, after having received Homer in his house, drew from him the story of the Iliad, and passed it off for his own. Homer, it is added, followed him to Chios, where Thestorides was reciting his works, and obliged the plagiary to fly from his presence. His kindest reception is said to have been at Chios, where, assuming gaiety from his easy circumstances, he composed the mock heroic of the Frogs and Mice. There, also, he married, and had two daughters, one of whom died a virgin, and the other is supposed to have perpetuated his race in the Homerides, who, for many generations, lived by reciting the Iliad and the Odyssey. On this account of Homer's residence in Chios, whether fabulous or true, are founded all the local traditions of places consecrated by his name. Among others, that of the hollow in the rock, which bears the name of his school, but which Tournefort and Chandlers have so entirely discredited.

It is not known what separated Homer from his family, but he quitted Chios, according to this account, at an advanced age, to recommence his wanderings. Those were principally at sea; and the knowledge which the poet displays of all the rude art that was known to the shipwright and seamen of ancient times, sufficiently evince that Homer had witnessed a considerable deal of navigation. Many of his voyages are said to have been disastrous; a circumstance which we can well believe, when we consider that the only ships which his experience enabled him to describe were destitute of anchors, and built without a nail of metal to secure them. An illness, which at last seized him, obliged him to stop at the island of Jos, and there he died. Strabo, Pliny, Pausanias, Aristotle, and Aulus Gellius, agree with this account of the place of his death and interment. A tomb in that island was long celebrated as the depository of his venerated remains, to which the states of Argos sent a solemn deputation every five years to offer libations.

Such are a few of the traits of his life which are given in the work attributed to Herodotus. Among the places that have laid claim to the honour of his birth, Antimachus thinks that he was born at Colophon; Aristarchus, at Athens; Pindar, at Smyrna; Aristotle supposes that he was born, as well as that he died, in the island of Chios. Suidas assigns him to Cyprus, others to Pylos, Rhodes, Mycæne, Ithaca, Salamis, and Argos. In fact, the guesses at his birth-place lead us pretty nearly over the whole map of Asia Minor, the Peloponnesus, and the Archipelago. Even Egypt has had its advocates for this distinction; so that the whole ancient world may be said to have claimed him. The poet Martial, when called upon for his opinion on the subject, could only reply in an epigram, that such a genius belonged to the world at large; and it is true that genius, like the light, belongs to all that can enjoy it; but unfortunately epigrams will not settle points of history. The Emperor Adrian applied to the oracle to solve the question, and was told that he was certainly born in Ithaca; but the oracle seems to have converted few to its opinion. The opinion of antiquity seems generally to lean towards either Chios or Smyrna having been his birth-place. Wood, who, after describing Balbec and Palmyra, travelled through Greece with the works of Homer in his hand, has adopted, as we have already mentioned, an ingenious mode of inferring, from the landscapes and natural similes of the poet, the place in which Homer first received his impressions of the scenery of nature. "If we survey," says that traveller, "the map of the world with attention, I think we may discover that his first impressions of the external face of nature were made in a country east of Greece, at least as far as we may be allowed to form a judgment, from his describing some places under a perspective, to which such a point of view is necessary; as, for example, when he places the Locrians beyond Eubœa. This piece of geography, though very intelligible at Smyrna or Chios, would appear strange at Athens or Argos. His description of the situation of the Echinades beyond sea, opposite to Elis, has something equivocal in it, which is cleared up, if we suppose it addressed to the inhabitants of the Asiatic side of the Archipelago. But if, with Mr Pope, we understand the words 'beyond sea' to relate to Elis, I think we adopt an unnatural construction to come at a forced meaning; for the old Greek historians tell us, that those islands are so close upon the coast of Elis, that in their time, many of them had been joined to it by means of the Achelous, which still continues to connect them with the continent, by the rubbish which that river deposits at its mouth. I think I can discover another instance of this kind in the 15th book of the Odyssey, where Eumæus, the faithful servant of Ulysses, is described entertaining his disguised master with a recital of the adventures of his youth. He opens his story with a description of the island of Syros, his native land, and places it beyond or above Ortygia. Now, if we consider that Ithaca was the scene of this conference between Ulysses and Eumæus, it will appear that the situation of Syros is very inaccurately laid down; for in reality this island, so far from being placed beyond or farther from Ortygia, should have been described as nearer to it. An ingenious friend thinks that καθυπερθεν may relate to the latitude, and that Homer meant to describe Syros as north of Ortygia; but I cannot help thinking that the application of high to northern latitudes is much later than Homer.

"As therefore the same description would have been perfectly agreeable to truth had it been made in Ionia, is it not reasonable to suppose that the poet received his early impressions of the situation of Syros in that part of the world, and had upon this occasion forgotten to adapt his ideas to the spot to which the scene is shifted? If my conjecture is thus far admitted, I beg leave to proceed to a farther use of it, in attempting to throw some light on this obscure expression ὀθιτροπαι ηελιοιο. It is important to that part of the poet's character now under consideration, to have his sense of these words restored, if possible; for they have been urged as an argument of his gross ignorance of geography, by those who think they relate to the latitude of Syros, and that this description places that island under the tropic * * * * *. I beg leave to carry the reader for a moment to the Asiatic side of the Archipelago, in order to examine whether a view of the landscape under that perspective offers any appearances to which those words can be naturally applied without violence to their literal meaning. No part of our tour afforded more entertainment than the classical sea prospects from this coast and the neighbouring islands, where the eye is naturally carried westward by the most beautiful terminations imaginable, especially when they are illuminated by the setting sun, which shows objects so distinctly in the clear atmosphere, that from the top of Ida I could very plainly trace the outline of Athos on the other side of the Ægean Sea, when the sun set behind that mountain. This rich scenery principally engaged the poet's attention; and if we consider him as a painter, we shall generally find his face turned this way. In the infancy, and even before the birth of astronomy, the distinct variety of this broken horizon would naturally suggest the idea of a sort of ecliptic to the inhabitants of the Asiatic coast and islands, marking the annual northern and southern progress of the sun. Let us suppose the Ionians looking south-west from the heights of Chios at the winter solstice, they would see the sun set behind Tenos and towards Syros, the next island in the same south-west direction; and having observed, that when he advanced thus far he turned back, they would fix the turnings (τροπαι) of the sun to this point. I submit it as matter of conjecture, whether this explanation does not offer a more natural interpretation of the passage than any which has yet been suggested. In pursuance of the same method of illustrating Homer's writings, I shall draw some conjectures with regard to the place of his birth, or at least of his education, from his similes. Here we may expect the most satisfactory evidence that an enquiry of this obscure nature will admit. It is from these natural and unguarded appeals of original genius to the obvious and familiar occurrences of common life, that we may not only frequently collect the customs, manners, and arts of remote antiquity, but sometimes discover the condition, and, I think, in the following instances, the country of the poet." After enumerating several similes to support his theory, the essayist proceeds to the following: "When the formidable march of Ajax is compared to a threatening storm coming from the sea, I must observe, as an illustration, not of the obvious beauty of the simile, but of the poet's country, that this can be no other than an Ionian, or at least an Asiatic storm; for it is raised by a west wind, which, in those seas, can blow on that coast alone. When, again, the irresistible rage of Hector is compared to the violence of Zephyrus buffeting the waves, we are not immediately reconciled to that wind's appearance, in that rough appearance so little known to western climates, and so unlike the playful Zephyrus of modern poetry. But before we condemn Homer as negligent of nature, we should see whether he is not uniform in this representation, and whether this is not the true Ionian character of Zephyrus. The very next simile of the same book is as much to our purpose, where the numbers, tumult, and eagerness of the Grecian army collecting to engage, are compared to a growing storm which begins at sea, and proceeds to vent its rage upon the shore. The west wind is again employed in this Ionian picture, and we shall be less surprised to see the same allusion so often repeated, when we find, that of all the appearances of nature, of a kind so generally subject to variation, there is none so constant upon this coast. For at Smyrna, the west wind blows into the gulf for several hours, almost every day during the summer season, generally beginning in a gentle breeze before twelve o'clock, but freshening considerably towards the heat of the day, and dying away in the evening. During a stay of some months in this city, at three different times, I had an opportunity of observing the various degrees of this progress, from the first dark curl on the surface of the water to its greatest agitation, which was sometimes violent. Though these appearances admit of variation, both as to the degree of strength, and the precise time of their commencement, yet they seldom entirely fail. This wind, upon which the health and pleasure of the inhabitants so much depend, is by them called *inbat*. The Frank merchants have long galleries running from their houses, supported by pillars, and terminating in a chiosque or open summer-house, to catch this cooling breeze, which, when moderate, adds greatly to the oriental luxury of their coffee and pipe. We have seen how happily the poet has made use of the growing violence of this wind, when he paints the increasing tumult of troops rushing to battle; but in a still, silent picture, the allusion is confined to the first dubious symptoms of its approach, which are perceived rather by the colour, than by any sound or motion of the water; as in the following instance. When Hector challenges the most valiant of the Greeks to a single combat, both armies are ordered to sit down to hear his proposal. The plain thus extensively covered with shields, helmets, and spears, is, in the moment of this solemn pause, compared to the sea, when a rising western breeze has spread a dark shade over its surface. When the reader has compared the similes I have pointed out with the original materials, which I have also laid before him, I shall submit to his consideration, as a matter of doubtful conjecture, whether the poet, thoroughly familiarized to Ionian features, may not have inadvertently introduced some of them in the following picture, to which they do not so properly belong. When Eidothea, the daughter of Proteus, informs Menelaus; at Pharos, of the time when her father is to emerge from the sea, the circumstance of Zephyrus, introduced in a description of noon, darkening the surface of the water, is so perfectly Ionian, and so merely accidental to the coast of Egypt, that I cannot help suspecting the poet to have brought this image from home."

That the Iliad displays abundance of geographical knowledge is certainly no internal proof, either for or against its being the work of one individual; but if we suppose it to be the work of a single genius, upon the grounds of that mind alone which had conceived so lofty a plan being able to accomplish its magnificent execution, we shall find in the geography of its author unquestionable proofs of his having been an extensive traveller. Strabo has left a commentary on the geographical parts of the Iliad and Odyssey; and others, such as Apollodorus and Menogenes, wrote on the same subject, though unfortunately only the titles of their works have reached posterity. Homer, in the midst of all his splendid machinery, was regarded as so faithful a painter of real existence, that his catalogue of the Grecian forces was respected as a valuable record in ancient Greece, and appealed to by its jurisprudence. In some cities it was enacted by law, that the youth should get the catalogue by heart. Solon, the lawgiver, appealed to it, in justification of the Athenian claim against the pretensions of the Megareans, when the right to Salamis was so warmly contested by Athens and Megara. And the decision of that matter was at last referred to five Spartan judges, who, on their part, admitted the nature of the evidence, and the affair was accordingly determined in favour of the Athenians. Three other litigated cases of property and dominion are said to have been determined by reference to Homer's geography. In Homer's age there was no other way of acquiring knowledge but by travelling. To the curiosity respecting his own species, which must have possessed the ardent mind of the poet, and impelled him to brave the dangers of sea and land, the veracious Strabo adds another very probable motive of his travels, which was the wish to make his fable accord with the mythology of the people whom he introduced on his scene of action. For this purpose, says Strabo, he consulted the religious records and the oracles that were suspended in the temples. At that period there were hardly any other historical monuments known. The priests held the sceptre of public opinion, and all history was consigned to the oracles. Diodorus says, that Homer visited the isle of Delphos. After the second sacking of Grecian Thebes by Alcmeon, the propheteess Manto, daughter of the famed Tiresias, had been sent to Delphi as making part of the spoils, where she acquired great renown by her talent for composing oracles. The meeting of Homer with such a lady is interesting to the imagination. Homer, says the historian, borrowed some striking verses of the oracle, either as ornament or authority to give weight to his works.

It would be curious to ascertain in what state Homer found the poetry of Greece when he commenced his career; but the question is involved in almost impenetrable obscurity. While he is hailed as the father, he was certainly not the inventor of poetry. According to the Greek library of Fabricius, there were seventy Greek poets anterior to him. The greater part of them were musicians. Among these Linus is cited, who, it is said, rehearsed the first expedition of Bacchus and Orpheus, who sung the Argonautic expedition. The assertion of Suidas, that Homer drew his story of the Iliad from that of Corinnos, who composed it during the Trojan war, seems to be only the dream of a lexicographer. Tzetzes, a versifier of the 12th century, who made a commentary upon Lycophron, and a bad poem called the Chiliade, would have us believe that Homer borrowed his Iliad from Dictys Cretensis, a writer to whom a manuscript, certainly most ancient, but not original, was ascribed, which was found in the reign of one of the Cæsars, in a tomb that was thrown open by an earthquake. When we are told that Dictys followed Idomeneus to the seige of Troy, and wrote a history of it in prose, we have quite enough of this phantom gazetteer. The story of Homer's purloining a manuscript poem from the priestess of Delphi, which is gravely repeated by Ptolemy Ephaestion, is almost too ridiculous to be worth noticing; and we are almost ashamed to mention another hypothesis, which has found an advocate in the absurdity of modern times, viz. the theory of Bryant, which supposes Homer to have found the materials of his Iliad in a temple of Egypt, and to have allegorized the contents under the fiction of Grecian names. According to this reverie, for it merits not the name of a theory, Menelaus, Agamemnon, Helen, &c. were all fantastic personages drawn from Egyptian theogony, and naturalized in Greece. Menelaus is evidently the Pharaoh Menes; Agamemnon is the Turkish word Aga prefixed to Memnon, whose harp resounded at the touch of the rising day. The wealthy Mycene never existed but in the vanity of Thucydides, and the credulity of Herodotus. Troy never existed but on the shores of the Nile. The historical part of this hypothesis is quite upon a par with its etymology, which, with its Agas and Memnons is not so diverting, but equally credible with Swift's derivation of Hector, Ajax, and Alexander.

The epoch of Homer has been not less a subject of disputation than his country. Herodotus says in his Euterpe, that he lived 400 years before his own (the historian's) time. In the chronicle of the Parian marbles, Homer is said to have been in his highest renown at the year of the chronicle 675, which would place the date of the Iliad 2707 years from the beginning of the present century; but venerable as the authority of the Parian marbles may appear, they seem to assign a later date to the great poet than his writings, and the manners of society which he describes, render probable. It is more consistent with his writings to suppose, that he was born not long after the siege of Troy, and that he had finished both his poems half a century after the town was taken. As the first interesting stories he heard when a boy were those of the exploits performed in the Trojan war, in his riper years he had still an opportunity of conversing with the old men who had been engaged in it. Their immediate descendants would, according to this supposition, be his contemporaries; he might know their grandchildren, and live to see the birth of the fourth generation. It is true, that this hypothesis makes the birth of Homer prior to the Ionian migration, which Thucydides places 80 years after the siege of Troy; but in this there is no solid objection, as we know that there were Ionians in Asia prior to the colony of that name being brought thither. The circumstance of Homer ascribing double the strength of modern men to one of the heroes of the Iliad, is no decisive proof that he looked back to a very distant period. Such fanciful exaggerations of the strength of men's immediate ancestors may be found in many romances of the middle ages, that must have been composed within fifty years of the lifetime of those personages to whom the poet ascribes a size and strength surpassing sober belief. The account which Homer gives of the family of Æneas continuing to reign over the Trojans after the Greeks had demolished Troy, though at variance with Virgil's fable, (a circumstance of no great consequence as to its credibility,) has all the air of having been drawn from contemporary information. Such an account of the family of Æneas it would have been difficult, as well as useless, for Homer to have forged. Now the succession of Æneas's great-grandchildren to the kingdom of Troy is the latest fact which the poet has left on record. The Æolian migration most probably disturbed that very generation in their possessions; and from Homer, who is ever minute in his historical accounts, being silent respecting such a disturbance, it may be inferred, that he did not live to be acquainted with it. The other and later era which has been assigned to our poet, makes him contemporary with Lycurgus; and, connected with it, there is a tradition of Homer and the law-giver having met in the island of Chios. But the picture of society which Homer exhibits, does not accord with this tradition. When we look to the verisimilitude of his descriptions, we must believe that he painted the natural world and all its manners from the life. There is no trace of his affecting to give it an antiquated air, or of wishing, as a modern poet would probably be inclined to do, to study simplicity of objects for picturesque effect; on the contrary, whenever he luxuriates in description, it is in painting artificial objects. Those who bring down Homer, therefore, so low as the time of Lycurgus, seem to forget that such a poet and such a legislator belong to different states of society. It has been questioned, and indeed it appears more than questionable, if the art of writing was known in the days of Homer. If we consult the poet himself upon this question, we shall find that in all his comprehensive picture of civil society, there is nothing that decidedly conveys an idea of letters, or of reading. The words Σηματα λυγρα, it is true, in the letter mentioned in the Iliad, which Bellerophon carries to the king of Lycia, have been quoted as a proof of alphabetical writing; but the generality of the term has much more the appearance of merely symbolical signs, or hieroglyphics, than of what we call writing. That such symbolical marks of thought were known in the rudest ages, there can be no doubt; and what has been already alluded to in the travels of the poet as a possible and even probable fact, namely, his consulting the records of different temples, must be taken with this understanding, that such records were, in all probability, also symbolical or hieroglyphical. The introduction of prose writing into Greece took place at so late a period, as to leave it by much the more probable supposition, that alphabetical writing was unknown to Homer; for when prose writing is of recent date, the alphabet cannot have been long in use. Homer, therefore, there is every reason to think, could neither read nor write; he recited his own works from memory, and hence it is little wonderful that he addresses the Muses as the daughters of that faculty of the mind. In modern times, when the memory is at once distracted by so many pursuits, and obliged to lean on so many artificial assistances, we are apt to under-rate its powers when employed upon a single object, and trained by habitual exercise upon that object. To an ancient poet like Homer, his memory was not only the mother of his muse, but his constant and indispensable guardian. The rhapsodists also preserved his works by oral tradition; and if their subsistence depended in a profession where there were rivals to detect the errors of each other, upon the accuracy with which they recited those poems, they were perhaps more safe from corruptions and interpolations, or at all events from omissions in recitation, than we might be apt to imagine, by ascribing the same lax exertions of memory to those reciters, which arise in modern times from the constant reliance upon writing. It may be doubted whether the rhapsodists made such havock in the sense of Homer, as the perverted ingenuity of *writing* commentators has made in that of Shakespeare.

Lycurgus, the legislator of Sparta, is said to have been the first who collected the fragments of Homer's poetry, during his travels in Asia Minor, and on his return by the island of Chios. Three hundred and seven years afterwards, Pisistratus, who erected at Athens the first public library that is mentioned in Grecian history, gave directions to a body of the learned for preparing an edition of the poet more correct than that of Lycurgus, and Solon and Hipparchus are said to have assisted in the undertaking.* At the destruction of Athens, in the invasion of Xerxes, the Iliad and Odyssey were taken from thence, and conveyed to Persia; and the despot himself seems to have respected this monument of taste and genius, since a part of the collection was found at Susa during the conquests of Alexander. It is perhaps to this epoch that we may assign the edition of the Odyssey which was rectified by Aratus, and which bears the name of the Aratæan edition. Alexander's enthusiasm for the memory of Homer is one of the noblest traits of his character. He charged Anaxarchus and Callisthenes to revise the copies of Lycurgus and Pisistratus; and Aristotle put the last hand to this precious edition, called the edition of the casket. After the battle of Arbela, when the conqueror had found, in the tent of Darius, a casket of gold, enriched with stones of inestimable value, he there deposit-

* Diog. Laert. Plut. in Hipparcho.

ed the two poems of Homer, and laid the treasure along with his sword every night under his pillow. After the death of Alexander, Zenodotus of Ephesus was charged, by the first of the Ptolemies, with the task of revising the edition of the casket. The last edition belonging to this period of high antiquity is that which Aristarchus, the greatest critic of his age, published under the auspices of Ptolemy Philometer, about nineteen centuries and a half ago, and which has served as a model for all collections of the works of Homer both in the middle ages and modern times.

The first edition of Homer since the invention of printing, was that of Demetrius Chalcondyles of Athens, and of Demetrius of Crete. It is entirely in Greek, is very magnificent, and now exceedingly scarce. It appeared at Florence in December 1488, in one folio, and had been collated with the commentaries of Eustathius. It was not till half a century after, that the works of Homer appeared again in Greek, with the entire commentaries of Eustathius.* This edition, the only complete one of the commentary of Eustathius, had long been regarded as a *chef d'œuvre* of sound criticism and correctness, till the learned discovered innumerable faults in it, by comparing it with MSS.; and the improvement of taste at last threw contempt on the barren prolixity of the commentary. Six years after the Roman edition of Eustathius, there appeared at Leyden the first esteemed edition of the prince of poets that had a Latin version. It contained also the scholia of Didymus, a commentator assigned to the age of Augustus. We notice here only those editions which may be said to form an epoch in the illustration of Homer. Joshua Barnes brought out at Cambridge the Greek and Latin texts of Didymus, with his own commentaries. The edition of Samuel Clarke appeared at London in 1734; that of Ernesti at Leipsic in 1764. Villoison, who was sent to Venice by the French government to collect ancient relics of literature, found in the library of St. Mark, an unique copy of the Iliad of the 10th century, with the remarks of sixty of the most famous critics of antiquity, such as Aristarchus and Zenodotus. It appeared, that this manuscript had been made from a copy in the library of the Ptolemies that was burnt by the barbarian Omar. Villoison remained two years at Venice to copy it with his own hand, and printed it in a folio volume, entirely Greek. As the original possessor of this literary treasure had joined to it many various and lost editions of the poet, this publication of Villoison may be called the *Homeri variorum* of antiquity. Wolff and Heyne are the two latest editors of Homer. Their merits have been so frequently treated of in the reviews and literary journals of our own time, that we forbear to descant upon them.

The memory of the great poet has received not only the homage of commentators and editors of his works, but of travellers, who have carried the reader's imagination to the scene of his action. Among these may be noticed Tournefort, the French naturalist, who understood the classical as well as his favourite vegetable world. Richard Pococke also carried his researches into Greece, though with less satisfaction to the public curiosity than into other quarters. Lady Mary Montague visited the Troad, though somewhat hastily, and saw, or imagined that she saw, the tomb of Achilles. Doctor Chandler visited Asia Minor and Greece in 1764-66, and made some conjectures that have not received much credit. In conjecturing the exact situation of Troy, and of the scene of Homer's travels, modern travellers have not been more successful than the ancients. Wood, who, on many points, makes ingenious and probable conjectures, is far from having settled the controversy of the Troad; and Chevalier and Gell, who succeeded him in the same attempt, have been less learned and much more gratuitous in their suppositions. To the real admirer of Homer, the controversy will probably appear of less importance than it has been made. For the difficulty of finding, at the end of 3000 years, the site of a town, of which an ancient poet says, that, in his own time, the very ruins had disappeared, (*etiam periere ruinæ*,) there is surely an apparent and sufficient reason in the changes and ravages which 30 centuries can produce. By such a difficulty, no sober mind would consider itself bound to adopt the wild idea, that no such war as the Trojan ever existed; although that supposition would render the Iliad a much more astonishing production than it really is.

The critical judgments that have been passed upon Homer would fill entire libraries. Horace assigns him a place as a moral teacher above Chrysippus and Crantor, the leaders of the two most famous schools of philosophy. Porphyry, in later times, composed a treatise on the philosophy of Homer. On the other hand, Pythagoras has condemned him to Tartarus, for having imparted false notions of the Divinity, and Plato banished him from his ideal republic. Yet, amidst the abstracted and elevated ideas of the latter philosopher, it is easy to perceive the most forced and sophistical reasons in his motives for condemning the poets, and he even redeems our opinion of his taste by the manner in which he ordains this banishment to be put in force. Plato, it should be recollected, admits in nature only two existences, the original idea, and the being which is the resemblance of or copy of that idea. By the original idea he understands God, or the Divine thought, and by the other existences all the forms which God created conformably to his own conceptions. All objects being then only copies of this first model, the arts which imitate them produce only copies of copies, which can serve for no good purpose. If then, says Plato, (speaking of his own ideal republic, which can hardly be called even the copy of a copy,) a poet should present himself amongst us who knows how to express every thing in nature by imitation, we should testify our veneration for him as for a sacred person, who deserves to be admired and cherished; but we should tell him that our political economy did not admit of such persons among us, and we should send him to another city, after having sprinkled him with perfumes, and crowned his head with flowers. It must be owned, that even the vanity of a poet could hardly be offended with such a sentence. When Plato comes to speak of Homer himself, it is with the deepest reverence for his genius. He owns that the respect and love which he has felt since his infancy for his writings almost arrests his tongue from condemning him, and that he considers him as the maker of all poets who have succeeded him, particularly those of the drama. After this apology, he demonstrates at great length that the gods of the Iliad are calculated to give us unworthy notions of divinity, a fact which, *philosophically* considered, it is not very difficult to prove. To exculpate Homer from this heavy charge, both his ancient and modern admirers have recourse to allegory; and in this system of explaining the Iliad, have mixed a vast deal of absurdity with a very small portion of truth. It is true that there was allegory and emblem both in ancient religion and philosophy; and some of the fictions of Homer carry their allegorical meaning in their appearance. But to see nothing in the whole Iliad but

* With the following title, *Homeri Ilias et Odyssea, Græce, cum Commentariis Græcis Eustathii, Archipiescopi Tessalonicensis; Romæ, apud Bladum et Giuntum,* 1542 and 1550, 4 vols. in folio.

moral abstractions personified, is an idea as intolerable to common sense as to poetical feeling. Such a forced explanation of the Iliad would after all leave the poem quite as immoral as it is in its plain interpretation. Suppose we take Jupiter for the power of God, Destiny for his will, Juno for his justice, Venus for his mercy, and Minerva for his wisdom, we shall still find the theology of Homer as defective as if we take things as they are in the Iliad; that is, if we understand his deities to be influenced by the passions of men. Homer painted the gods just as the vulgar belief represented them. It was impossible for him to have done otherwise, for he could not create a new religion; but if we could suppose it possible for him to have surpassed the limits of human intelligence, and to have anticipated the higher notions of Plato respecting the divinity, it would not have been his interest as a poet to have refined his mythology into the pure theism of the philosopher. The moment that he had ceased to consider the inhabitants of Olympus as impassioned beings, there was an end to all our interest in their actions. Divinity, in its true attributes, is not a subject for romantic fable.

The touch-stone of more recent refinement in sentiment and manners has been applied with the same absurdity to his heroes, as the standard of pure theology has been to his divinities. In the times which he described, the power of a man's body constituted the greater part of his estimation in society. He who could support the heaviest load of armour, and who could give and take the hardest blows, was a formidable man or a hero. When this superiority was once recognised, it established his rank in exact comparison with others; and hence it is so common in Homer's heroic descriptions to hear a warrior of acknowledged bravery confess that another is superior to him. At present the equality of arms and the principle of honour would make a man ashamed of such a confession. But in Homer, Æneas says without shame to Achilles, "I know that thou art more valiant than me," which is, in other words, "I know that thou art stronger." Æneas adds, "*but, however, if some god protects me, I shall be able to conquer.*" And this is a general principle, which to a certain extent may be said to constitute all the morality of the Iliad, namely, that power, success, and wisdom, all come from the gods. When Agamemnon excuses his outrage upon Achilles, he says that some god had disturbed his reason. It is the protection of this or that divinity that gives the Greek and Trojan heroes each a triumph in his turn; it is the gods who spread consternation among the armies, or inspire them for the combat; but we must not regard this intervention of the deities as diminishing the glory of the successive warriors. We see clearly that Homer does not lessen their importance on that account. On the contrary, the epic spirit of the piece is heightened by this machinery; because it is clearly perceived, that the heroes thus favoured of heaven, rise in the opinion of their associates and adversaries on that account. Achilles excepted, there is not a hero of the Iliad who does not at some time or other retire before another. What distinguishes the bravest, such as Ajax and Diomede, is, that they fight as they retreat. And it may be observed, to the glory of Homer, that, in spite of this divine intervention, which we might expect to confound all distinctions of human bravery, he still preserves the distinctive character of greatness in his heroes, even when yielding to supernal influence.

It is a singular trait in the Iliad, that the sullen rest of its hero Achilles should form the main-spring of the action. His absence appears to be the cause of the disasters of his countrymen, which prolong the contest. This, so far from being a defect in the plan of the action, is an artifice which carries internal evidence of the whole plan being the invention of one great mind; all the prowess of the successive agents that are described, ministers to the ultimate triumph of him by whom Hector is to fall. In the fire and spirit of this ancient hero, Homer has not certainly left what it would be absurd to seek for in ancient poetry, a model of pure morality; but he has consummated the picture of all that must have commanded the respect of warlike and barbarous times, and has in fact pourtrayed a being that would, under different circumstances, in all ages predominate over the rest of his species, by his pride and energy. It may be necessary to notice the vulgar tradition of his being invulnerable all over but in the heel; but Homer does not debase the courage of his hero by such a fable: nor is his character of stern pride unrelieved by circumstances that touch us with an interest in his fate. His youth, his beauty, his maternal descent from a goddess, the certain prediction that, while he could find no conqueror, he was one day to perish in the Trojan war, prepare us for the part of no vulgar hero.

To enter on a minute criticism of the Iliad would far exceed our limits. The most superficial readers are probably acquainted with the hackneyed objections that have been made to its prolixity of speeches and military details; to the minuteness and surgical description of wounds; the ferocity of its manners, and the abusive epithets which the heroes exchange when they quarrel. The French criticism of La Motte and Perrault has gone even so far as to blame the simplicity of its manners, and to throw contempt on Achilles for cooking his own dinner. The majority of those objections are frivolous. It is true that the primitive abundance of expletives, and the Greek loquacity of Homer, may at times be excessive; but the dramatic air which the constant dialogue gives to the Iliad, would be ill exchanged for the conciseness of mere narrative. The diversity of Homer's battles, as an eminent critic has observed, shews an invention next to boundless; the technical terms of the wounds that are described appear technical to us, only because the language of science is derived from Greek; and the fastidious taste that is offended with the bold simplicity of ancient manners, would with equal propriety find fault with Salvador Rosa for not having adorned his mountain scenery with terraces and gravel-walks. Achilles cooking his dinner is certainly a considerably more poetical personage than Louis the XIV. would have been, if La Motte had made him the hero of an Epopee, treading on a velvet carpet, and commanding the maitre d'hotel to prepare his fricasees.

The excellencies of the Iliad, independent of the beautiful and sonorous language to which it belongs, may be summed up in the vastness and variety of the picture of existence which it spreads before us; the spirit and perpetual motion of its agents; the relieving interchanges of an interesting inferior world, and a heaven of voluptuous and gay mythology; the progressive swell and importance of the story; and the art with which the very rest of Achilles is made subservient to the evolution of his grandeur; the full physiognomy of human character displayed in every age and situation of life; the unstudied strength of his circumstances in description; and the contagious spirit with which he seizes the mind to sympathy with his martial passion: Such an apocalypse of life, from its sublimest tumults to its minutest manners, was never communicated by another human imagination.

If Homer has erred at all, it is from the wealth, or rather from the pathos, of his genius, in giving so strong a countervailing interest to the character of Hector. This unquestionably diminishes our exultation in the triumph of Achilles. Yet who would wish that fault undone? Here is the generosity of genius, even in the poet, scorning the bigotry of national hatred that would depreciate the heroism of an enemy. It is, perhaps, repeating superfluously, what few have to be told, that the character of Achilles, so unlike the *inexorabilis acer* of Horace, has a relief of the noblest traits of compassion and generosity amidst the fury of his savage passions. The concluding book of the Iliad teems with the most touching circumstances of his generosity. He receives King Priam; joins him in his tears at the recollection of their respective losses; perfumes the body, and orders it to be kept out of the father's sight, lest it should shock the grief of the king; places it himself in a litter, fearing that Priam might burst into a fit of exasperation, and should exasperate himself also; and, finally, refreshes him with food and sleep in his tent, and takes him by the right hand as a friend. In recognizing such traits of compassion in the proverbially savage Achilles, one is tempted to believe, that humanity is not so modern a virtue as some would have us believe.

The Odyssey speaks less to the imagination than the Iliad, but it introduces us to a still more minute and interesting view of ancient manners, and it awakens with deeper effect the softer passions that appear but rarely in the other poem. It is strange, that La Harpe, who redeems much of his bad French taste by an apparently sincere enthusiasm for the genius of Homer, should say, that the Odyssey is devoid of the eloquence of sentiment. If by sentiment we mean the sickly misanthropy, or the rampant enthusiasm which distinguishes so many modern productions, there is certainly nothing of the kind in the Odyssey; and the difference of circumstances in which human nature was then placed must be fairly estimated,* before we can even pardon many maxims of moral conduct which Ulysses practically avows: but if by sentiment we mean the unsophisticated feeling of the heart, where, it may be asked, shall we find it, if it is not found in the pathetic situations of Telemachus, the conjugal love of Penelope, and the return of Ulysses to his home, with all the circumstances that attend it, his aged dog expiring with joy at his feet, and his father relating to him, while he retains his disguise, all the little circumstances of his childhood that could awaken his tenderest associations?

Besides the Iliad and Odyssey, Homer is said to have composed another poem, entitled *Margites*. It is now lost. It is said by some to have been a comedy; but, from some verses in the contest between Homer and Hesiod, it may be rather conjectured to have been a piece of mockery and satire. Margites is the name of a person in a verse that is preserved by Plato, who is described as knowing many things, and knowing nothing well. Such a character may have been the original hero of Homer's satire, and been thus damned to everlasting memory, like the Mac Flecknoe of Dryden. The little mock heroic of the *Battle of the Mice and Frogs*, is well known, from Parnell's translation, to the English reader. Professor Heyne supposes it spurious, because he finds scarcely any verses in it that breathe the spirit of Homer; but this is no decisive argument, as Homer might be the worst of all parodists, though the best of original poets. The hymns attributed to him deserve more attention, as, along with those of Callimachus, they form a curious historical monument of the popular superstitions of antiquity. Unfortunately, in the numerous collection of them which Clarke's *Homer* exhibits, there is only one, perhaps, viz. the *Hymn to Apollo*, which is not apocryphal; and the scholiast of Pindar throws doubts even upon that one. But Thucydides recognised in that ode the touch of Homeric genius, and the suffrages of a scholiast has certainly no right to be put in competition with that of so elegant a writer. As to the epigrams that have been occasionally ascribed to him, they carry internal proof of their spuriousness. (*z*)

HOMICIDE, (*Homicidium*,) in law, is the killing of any human creature. This act is of three kinds, according to the circumstances in which it is perpetrated, viz. *justifiable*, *excusable*, and *felonious* or *culpable*.

Homicide is *justifiable*, when the act is committed under some unavoidable necessity, and infers no degree of guilt or blame; as, for instance, by virtue of such an office as obliges one, in the execution of public justice, to put to death a malefactor, who hath forfeited his life by the laws and verdict of his country. This act is also considered justifiable in some cases, either for the advancement of public justice, or for the prevention of some atrocious crime.

Homicide is *excusable*, when a person engaged in a lawful act is, without intention, the cause of another's death. Excusable homicide is of two kinds; either *per infortunium*, by misadventure, or *se defendendo*, in self-defence, including homicide upon *chance-medley*, whereby a man kills another, who assaults him, in the course of a sudden brawl or quarrel.

*Felonious* or *culpable* homicide has different degrees, which distinguish the offence into *manslaughter* and *wilful murder*; in the last of which, the act, being committed from malice and forethought, admits of no defence, and subjects the criminal to the highest punishment of the law. See Blackstone; Erskine; and Hume *on Crimes*. (z)

HOMOLOGOUS Sides and Angles. See Geometry.

HOMOPHONI, in music, denotes the unison whose ratio is 1=1, and whose expression in Farey's notation is 0. See First *Minor*.

HONAN. See China.

HONDURAS, or Hibueras, a maritime province of the Spanish kingdom of Guatimala in America, which the Spaniards calculate to extend 185 leagues from north to south, and 50 from east to west. The surface is in general mountainous, and is intersected by deep vallies, conducting numerous rivers down to the sea; but part of the

* Many Oriental countries retain to this day manners of society nearly similar to those described in the Odyssey. There is nothing more remarkable in those manners than the degree of refinement to which profound dissimulation is carried in all ranks. The stranger accommodates his language much less to his own sentiments, than to his hopes and fears, or the countenance of those he meets. The arts of disguise are, in those countries, the great arts of life; and the character of Ulysses would form a perfect model for those who wish to make their way with security and respect. Cruelty, violence, and injustice, are also so evidently the result of defective government, that it is unnecessary to look for any other general cause of the scenes of this sort with which Homer abounds, in common with other ancient writers, and agreeable to the present manners of those countries. For, when every man is, in a great measure, judge in his own cause, vices of this class are not only more frequent, but, in *foro conscientiæ*, less criminal than in a civilized state, where the individual transfers his resentments to the community, and private injury expects redress from public justice. Where the legislature does not engage for our personal security, we have a right to use such means as are in our power to destroy the aggressor who would destroy us. In such cases, bodily strength and courage must decide most contests, while, on the other hand, craft, cunning, and surprise, are the legitimate weapons of the weak against the strong. In the heroic times, homicide was so common, that we see the poet alluding to a fugitive murderer taking shelter under the roof of a stranger, (to escape, not public justice, but the revenge of the relations of the deceased,) as a familiar occurrence in life.

coast is extremely low and marshy. A hot and humid atmosphere renders the province unhealthy, unless on the shore, where regular breezes refresh the inhabitants; and here epidemical diseases rarely prevail. Thunder showers are frequent during the warmest season, sometimes raging with great violence. This province is penetrated by a large bay, called the Bay of Honduras, to which our notice shall be more particularly directed: the coast abounds in dangers to the mariner from rocks and shoals; and all along its margin are keys, that is, peninsulas or promontories, between creeks and the mouths of rivers. These keys are known by different names, as St George's key, Turneff key, Ambergrease key, and the like; and some of the islands pass by the same denomination.

Some authors affirm, that gold and silver are found in Honduras; but, according to the late traveller Humboldt, it scarcely presents any metallic mines. Vegetation is in remarkable luxuriance, and the plants numerous and diversified. Grapes are produced twice a year from the vines; sugar canes, coffee, cotton, and indigo, are abundant, and also grain of several kinds; but the inhabitants are too indolent to avail themselves of the benefits of nature. The most important plants, in a commercial view, are mahogany and logwood; the former is employed for all descriptions of furniture in Britain and America, and the latter for dyeing. Chiefly for the purpose of obtaining these two commodities, a British settlement has long been established in the Bay of Honduras; and a vast quantity of the former is exported annually. The mode of procuring it, is to dispatch a skilful negro to climb the highest trees on lofty places, for the purpose of discovering mahogany in the woods, which is generally solitary, and visible at a great distance, from the yellowish hue of its foliage. A gang of from ten to fifty slaves is then sent out to erect a scaffold around each tree that is selected, and to cut it down about twelve feet from the ground. When felled, the logs are, with much labour, dragged to the banks of the streams, and being formed into rafts, sometimes of 200 united, are floated as many miles, to places where the rivers are crossed by strong cables, and then the owners separate their respective shares. It is said that the boughs and limbs afford the finest wood, but in Britain mahogany is more valued on account of size; and none is allowed to be exported to the United States of America exceeding 20 inches in diameter. The logwood, on the other hand, affects low swampy grounds, growing contiguous to fresh water creeks and lakes, on the edges of which the roots, the most valuable parts of the wood, extend. It is sought in the dry season, and the wood-cutters having built a hut in the vicinity of a number of trees in the same spot, collect the logs in heaps; and afterwards float up small canoes in the wet season, when the ground is laid under water, to carry them off. This is considered a very unhealthy employment.

Many wild animals inhabit the province, among which are two kinds of tiger, as generally described; but they are more probably of the leopard species, the Brasilian and black tiger. Both of them are fierce; they are said sometimes to attack man; but their depredations are chiefly confined to cattle. The tapir, which is nearly the size of a small cow, is reputed to inhabit the thickest parts of the forests, in the neighbourhood of creeks and rivers, and is very rarely to be seen by day. There are different kinds of wild hogs, three species of the armadillo, and numerous monkeys. Of birds may be named the turkey, concerning whose native country naturalists have expressed doubts; but here it lives in pairs in the most sequestered recesses of the woods, and cannot easily be taken alive. It never survives in captivity, and the young hatched from eggs, generally wander away to the original haunts of the mothers. The toucan, oriole, macaw, and pelican, are common. A great quantity of honey and wax are obtained from the bees of this country, which construct their combs in holes of the earth. The rivers abound in fish; and the manati and turtle are the constant objects of pursuit on the shores.

In regard to the inhabitants of Honduras; the total population of the province, consisting of natives, Americans, Spaniards, and English, with African slaves, is said to have diminished. We are quite ignorant of any calculations as to its amount; but that of the British settlement in the Bay of Honduras is computed at about 3700, or somewhat more, of which there are 200 white inhabitants, rather more than 500 people of colour and free blacks, and 3000 negro slaves. Neither are we acquainted with the precise geographical limits of the settlement, or the number, extent, and position of the towns belonging to the Spaniards. Formerly the principal English establishment was at St George's Key, which is a healthful and agreeable situation, still containing a number of good houses, but now it is at Balize, a town at the mouth of a river of the same name, called Wallix by the Spaniards. It consists of about 200 houses, many of which are spacious and well finished; all are built of wood, and for the most part raised 8 or 10 feet from the ground on mahogany pillars. An agreeable and picturesque effect is produced by groups of lofty cocoa trees, and the foliage of the tamarind thickly interspersed, while they afford to the inhabitants a grateful shelter from the fervour of the sun. This town is accessible to an enemy only from the sea; for it is totally environed behind by a morass, extending many miles into the country, which, during the rainy season, is nearly covered with water. A strong fort lately erected in a commanding situation guards the channel of approach; and the inhabitants have formed a militia as a farther means of defence.

The principal trade of the British settlement consists in the export of mahogany, logwood, and tortoise shell; while the articles of import are chiefly for the consumption of the settlers, being those of British manufacture, and salted provisions for the slaves. They also obtain cattle from the Spaniards, who, besides, carry on considerable traffic in cotton bed-covers, which are much esteemed in that province. The Bay of Honduras is reckoned a very favourable situation for trade; and the preservation of the settlement occasions no expence to government, as the revenue somewhat exceeds the expenditure.

During the last and preceding century, the coast and islands of Honduras were a great resort of pirates, who found sufficient subsistence and concealment to enable them to commit their ravages against defenceless vessels. On the largest island, called Ruatan or Rattan, about 30 miles long, rich and fertile, there is a small Spanish outpost; but, according to Philip Ashton's *Memorial*, it was uninhabited in 1723. Previous to the year 1763, English mercantile adventurers had established themselves on the coast, at which time the court of Spain admitted them to remain, on condition that their fortifications should be demolished. However, all were taken prisoners or dispersed in 1782; and having been enabled to return in 1784, under a treaty with the Spanish government, they finally settled at Balize. Here they remained undisturbed until the year 1798, when the Spaniards, having fitted out an armament, made an attempt to capture the town. They were speedily repulsed, and the colony has never since had to dread any enemy. See Alcedo *Diccionario*; Uring's *Voyages and Travels*; Ashton's *Memorial*; and Henderson's *Account of the Settlement of Honduras*. (c)

HONEY is a saccharine vegetable secretion, most abundant in the nectarium of flowers. Some authors consider it an elementary principle of all vegetables without exception: They suppose that it exists in every part of plants, and that their life is dependent on its presence. We do not know, however, that the saccharine matter of plants is universally convertible into honey. It is much more copiously diffused in certain flowers than in others, both of the same and of different species: in some it cannot be recognised, and the weather has always a powerful influence on its secretion. A hot and sultry atmosphere, charged with electricity, is considered most favourable to the production of honey. Honey seems to be of various quality, sometimes of a grateful taste and odour, sometimes pungent and bitter, or even of a deleterious nature, which probably originates from the flowers.

This substance appears in its sensible shape when collected by bees, a tribe of insects which may almost be considered as reduced under the dominion of man. But naturalists are not agreed whether honey undergoes a particular elaboration in their bodies, thence deriving its flavour and consistence, or whether it is merely collected, and is still seen in its pristine state. A bee having entered a flower, apparently absorbs the liquid nectar by its proboscis, whence it is conducted to an intestinal sac exclusively appropriated for its reception, commonly called the honey bag. The animal is then plump and cylindrical, and returning to the hive, disgorges the contents into cells selected for that purpose. By repeated accumulations the cell is filled, and then sealed by concentric circles of the thinnest wax, begun at the circumference and closed in the centre. There it is kept, as is supposed, for winter store; at least no other use is assigned to it: but we cannot be sufficiently reserved in classing distant anticipations among the instincts of animals. It is principally in the more civilized countries that bees are confined in hives. In many places, they form their combs in trunks of trees, and also in cavities of rocks, and the earth. In India, there is a species which constructs a single comb of very large dimensions, attached to the under part of the bough of a tree well sheltered. During winter, a great portion of the honey thus preserved is undoubtedly consumed; and it is understood that the safety of an ordinary hive is endangered, if there be a smaller quantity than twelve pounds at the end of autumn. Honey is supposed by some of the most acute naturalists, as Huber, to contain the principles of wax, whence the bees are enabled to build their combs without collecting it from vegetables; and he describes a method of arranging a hive, whereby they may be forced to work in this substance. The relative proportions of honey and wax in a hive are not ascertained; the latest observations allot about three or four pounds of wax to one hundred of honey.

The finest honey is collected by swarms leaving the parent hive, and it always becomes darker and coarser in proportion to the age of the combs. Its quantity and quality, both depend very much on the nature of the surrounding vegetation; hence in cultivating bees, particular attention should be paid to the abundance of flowers. Honey and wax are very considerable articles of traffic, and profit may undoubtedly be derived from bees with little trouble and trifling expence. Most part of the honey imported into Britain comes from Germany, Russia, and America, with which we could very well dispense by a little more attention to bees. Probably ten times the number of hives now existing could be subsisted in the country. Mr Huish, a late author, by a moderate calculation, endeavours to show, that in the year 1817, the profit from one hive purchased in 1812 should be 57*l.*: 15: 4, while ten remain to carry on the stock. He considers the chief obstacle to the culture of bees to centre in the use of the common hive; and that, on the whole, it is better that they should be destroyed at the end of the season.

The combs being withdrawn from the hive, are to be laid on a fine sieve above a vessel, into which the best honey will be received: gentle heat will disengage the next in quality; and the whole remaining mass may be then subjected to a press, whereby the remainder will be extracted. A certain quantity of wax and other impurities always pass over, which renders it necessary to expose the honey contained in the vessels again to heat, and this admits their rising to the surface, when the whole can be removed. The purification of honey is conducted after a different process, according to the country wherein it is practised: and premiums have been offered for the best mode of doing so on the continent. Honey should be chosen of an agreeable odour, sweet, clear, and new; but it may be preserved a year or longer in the comb, still retaining most of its properties. See Huber, *New Observations;* Huish, *Treatise on Bees;* Reaumur, *Memoires sur les Insectes;* Bonner *on Bees;* and our article Bee. (*c*)

HONITON, a burgh and market town of England, in Devonshire, is situated in a delightful vale, upon a gentle eminence, on the south side of the river Otter, commanding a fine view of the surrounding country, which is extremely beautiful. It consists chiefly of a spacious and handsome street, running from east to west, through which passes the high road from Exeter to Chard. Two other streets cross this at right angles, one on the north-west leading to Cullumpton, and the other on the north leading to Taunton. Through the principal street flows a stream of pure water, which the inhabitants receive from a dipping-place opposite almost every door. The buildings, which are almost all modern, were covered with slate, in consequence of the town having been twice destroyed by fire in 1747, when three-fourths of it were reduced to ashes, and, in 1765, when nearly 180 houses were consumed. In 1790, and 1797, it suffered considerably from fire. There is a chapel in the town, called All-Hallows chapel, which is a neat structure, with a square embattled tower of flint. It was built in 1765. The church is situated on a high eminence, about three quarters of a mile from the town, and contains some ancient monuments. There is here a small free-school for boys, and a school of industry for girls; and three meeting-houses for the Presbyterians, Baptists, and Independents.

The town is governed by a portreve and bailiff, who are chosen annually. It sends two members to Parliament. The number of voters is 350. The chief articles of manufacture here are broad lace and edgings, which are principally sent to London. A great trade is carried on in butter, which is also sent to the London market.

The following is the population abstract of 1811, for the burgh and parish:

| | |
|---|---|
| Number of inhabited houses | 581 |
| Number of families | 581 |
| Do. employed in manufactures | 349 |
| Males | 1280 |
| Females | 1455 |
| Total population | 2735 |

See Polywhele's *History of Devonshire;* and the *Beauties of England and Wales*, vol. iv. p. 299.

HOOF. See Veterinary Medicine.

HOOGHLY, a river in Bengal, and the port of Calcutta, is formed by the junction of the Cossimbazar and Jellinghy, the two westernmost branches of the Ganges.

The Hooghly, though by no means the largest branch, has the deepest outlet to the sea, and is considered by the Hindoos as the true Ganges, or most sacred part of that river. It is the only branch which is commonly navigated by large vessels; but its entrance and passage are nevertheless extremely dangerous, not so much from the shallowness of the channel, as from the number of the sand-banks which project into the sea. At its junction particularly with the Roopnarrain, there is a large sheet of water formed, which is full of shoals; and, as the bed of the Hooghly turns to the right, many vessels are lost, by being carried, with the force of the tide, up the Roopnarrain, which more directly faces the approach from the sea. There is also, at this bend of the Hooghly, a dangerous sand, named the James and Mary, around which the channel seldom continues the same for eight days in succession, and requires very frequent surveys. The bore, which commences at Hooghly point, where the river first contracts itself, is perceptible above the town of Hooghly, nearly seventy miles distant; and so rapid is the progress of the tide, that it passes through this extent in four hours. It does not run on the Calcutta side; but proceeds along the opposite bank, from which it crosses at Chitpoor, about four miles above Fort William, and rushes with great violence past Barnagore, Duckinsore, &c. At Calcutta, it sometimes occasions an instantaneous rise of five feet, and, upon its approach, it is necessary for boats to quit the shore, and go for safety into the middle of the river. (*q*)

HOOGHLY, a district in the province of Bengal, extends along both sides of the river Hooghly, and is situated principally between the 20° and 23° of North Latitude. It is bounded on the north by the districts of Burdwan and Kishenagur; on the south, by the sea; on the west, by Midnapoor; and on the east, by Jessore, and the Sunderbunds. It consists entirely of low, flat, and fertile land; but, though one of the earliest of the East India Company's acquisitions, and immediately adjoining to the town of Calcutta, where a constant market is found for its produce, three-fourths of it still remain in a state of nature, the habitation of alligators, tigers, and reptiles. The division nearest to the sea, particularly, is covered with jungle, and is remarkably unhealthy, and thinly inhabited. Salt of an excellent quality, (and possessing, in the opinion of the natives, a peculiar sanctity, because extracted from the mud of the most sacred branch of the Ganges,) is manufactured on the coast of the government. The whole district is intersected by rivers, so as to render it capable of complete inland navigation; but these remote streams are greatly infested by river pirates, who rob in gangs, and frequently apply torture for the purpose of extorting the discovery of concealed property. (*q*)

HOOGHLY, an ancient town in the last mentioned province, situated on the west side of the river of the same name, about twenty-six miles above Calcutta, in North Latitude 22° 54′, and East Longitude 88° 28′. It was a place of considerable importance under the Mogul government, and was the seat of their custom-house for collecting the duties of merchandize carried up the western branch of the Ganges. It is now comparatively of little note, but still tolerably flourishing, and well inhabited. The French, Dutch, Portuguese, and Danes, had originally factories at Hooghly; and, in 1632, while in the possession of the Portuguese, it was the scene of the first serious quarrel between the Moguls and Europeans. After a siege of three months and a half, it was carried by assault by the Mogul army, and the greater part of the Portuguese were put to the sword, or taken prisoners. In 1640, the English were permitted to build a factory at this place; but their trade was greatly restricted, and subject to continual exactions. In 1686, they were involved in hostilities with the native powers. in consequence of a quarrel between some of their soldiers and those of the nabob; and though peace was speedily restored, they withdrew their settlement to Chittanuttee, or Calcutta. See Bruce's *Annals of the East India Company*; Rennel's *Memoir of a Map of Hindostan;* Lord Valentia's *Travels;* and Hamilton's *East India Gazetteer.* (*q*)

HOOKAH is the name of a pipe for smoking, in great use among eastern nations. It consists of a globular vessel of glass, nearly filled with water, in which two tubes are inserted; a perpendicular one which holds the tobacco, and an oblique one to which the mouth is applied. The smoke is thus rendered peculiarly agreeable, by passing through the water.

HOOKE, Robert, an eminent natural philosopher, was born at Freshwater, on the west side of the Isle of Wight, on the 18th July 1635, and for the first seven years of his life was in a very infirm state of health. His father, who was the minister of the parish, educated him under his own roof, as he had been such a sickly child that he was not expected to live. He was at first intended for the church; but after beginning the Latin grammar, his health became so weak, and he was so much subject to headache, that his parents despaired of making him a scholar. Being thus left to the direction of his own genius, he amused himself in the formation of toys, and he even succeeded in the construction of a wooden clock, that exhibited in a rough manner the hours of the day, and in the formation of a full rigged ship, about a yard long, which had a contrivance for firing some small guns as it sailed across a piece of water. This circumstance led his parents to the resolution of putting him an apprentice to a watch-maker, or a painter; but by the death of his father in 1648, neither of these plans were adopted. He was placed, indeed, for a time under the celebrated painter Sir Peter Lely; but he soon found from experience, that he had chosen a profession which the state of his health would not allow him to prosecute. He was therefore sent to Westminster school, and was kindly taken into Dr Busby's house, where he made great progress in Latin, Greek, Hebrew, and other oriental languages. He made also considerable progress in Euclid, and, as Wood informs us, he invented and communicated to Dr Wilkins *thirty different modes of flying!*

In the year 1650, according to Mr Wood, and 1653, according to Mr Waller, he went to Christ's Church, Oxford. In 1655 he was introduced to the Philosophical Society there. He was employed to assist Dr Willis in his chemical experiments; and he afterwards laboured several years in the same capacity with Mr Boyle. He received instructions in astronomy from Dr Seth Ward, Savilian professor of that science in Oxford, and was henceforth distinguished for the invention of various astronomical and mechanical instruments, and particularly for the air-pump which he contrived for Mr Boyle.

In consequence of perusing Ricciolus's *Almagest*, which Dr Ward put into his hands, he was led, in the years 1656, 1657, and 1658, to the invention of the balance or pendulum spring, one of the greatest improvements which has been made in the art of horology: (See Horology, chap. iii. p. 137.) He mentioned this discovery to Mr Boyle, who, as Dr Hooke remarks, "immediately after his Majesty's restoration, was pleased to acquaint the Lord Brouncker and Sir Robert Moray with it, who advised me to get a patent for the invention; and propounded very probable ways of making considerable advantage by it. To induce them to a belief of my performance, I showed a pocket-watch, accommodated with a spring applied to the arbor of the balance to regulate the motion thereof. This was so well approved of, that Sir Robert Moray drew me up the form of a patent; the principal part whereof, viz. the description of the watch so regulated, is in his own hand-writing, which I have yet by me. The discouragements I met with in the management of this affair, made me desist for that time." In the agreement between Dr Hooke, Mr. Boyle, Lord Brouncker, and Sir Robert Moray, which seems to have been drawn up about 1663, it was provided, that out of the first 6000*l.* of profit, Dr Hooke was to have three-fourths; of the next 4000*l.*, two-thirds; and of the rest, one half: but the other partners in the patent very improperly insisted upon the insertion of a clause, giving to any of themselves the sole benefit of whatever improvements they might make upon his invention.

About the same time Hooke contrived the circular pendulum, which was shewn to the Royal Society in 1663, and which was afterwards claimed by Huygens. This pendulum, which is described in Hooke's Animadversions on the *Machina Celestis* of Hevelius, does not vibrate backwards and forwards, but always in a circle, "the string being suspended above at the tripedal length, and the ball fixed below, as suppose at the end of the fly of a common jack. The motion of this circular pendulum is as regular, and much the same with those mentioned before; and was made to give warning at any moment of its circumgyration, either when it had turned but a quarter, a half, or any lesser or greater part of its circle. So that here you had notice not only of a second, but of the most minute part of a second of time." See Derham's *Artificial Clock-maker*, p. 97.

The establishment of the Royal Society in 1660, afforded to Dr Hooke numerous opportunities of extending his reputation. He published in 1660, a small tract on the ascent of water in small tubes by capillary attraction, in which he shewed that the height of the water was in a certain proportion to their bores. A debate arose on this subject in the Royal Society in April 1661; but Hooke's replies were considered so satisfactory, and raised him so high in the estimation of the Society, that in 1662 he was appointed curator of experiments to that distinguished body. He was also one of the 98 persons who were declared members of the Royal Society, at a meeting of the council held May 20th, 1663, by virtue of the power given them by the charter for two months. He was admitted to the society on the 3d of June, and was peculiarly exempted from all payments. In the same year he took his degree of Master of Arts, and the Repository of the Royal Society in the White Gallery of Gresham College was committed to his care. About this time he drew up a list of enquiries for the use of those who might have occasion to visit Greenland or Iceland. Those which respect Iceland are numerous and interesting; and one of them is particularly deserving of notice: "Whether spirits appear; in what shape; what they say and do; any thing of that kind very remarkable, and of good credit?" In May 1664, he delivered the astronomical lecture at Gresham College for Dr Pope, who was absent in Italy; and in the same year, Sir John Cutler gave him a salary of 50*l.* per annum, for reading a course of mechanical lectures, under the direction of the Royal Society. These lectures were afterwards published in 4to, in 1679, under the title of "*Lectiones Cutlerianæ*, or a collection of lectures, physical, mechanical, geographical, and astronomical, made before the Royal Society on several occasions, at Gresham College; to which are added divers miscellaneous discourses." On the 11th January 1664, the Royal Society settled upon him a salary of 30*l.* per annum for life, for his labours as curator of experiments; and on the 20th of March of the same year, he was appointed to succeed Dr Dacres as professor of geometry in Gresham College. In the year 1665, Hooke published his "*Micrographia*, or some physiological descriptions of minute bodies, made by magnifying glasses, with observations and enquiries thereupon." All the figures in this work were drawn with his own hand, and many of them are a kind of standard representations, which have been copied by succeeding authors. The best are those of the common mite, flea, louse, gnat, and ant. A new edition of it with abbreviated descriptions appeared in 1745, in which the baroscope, the hygroscope, and the engine for grinding optic glasses, were wholly omitted. During the recess of the Royal Society, on account of the plague in 1665, he accompanied Mr. Wilkins and other ingenious authors into Surry, where they continued their philosophical labours. In 1665, at one of the first meetings of the Royal Society, Dr Hooke produced a very small quadrant for observing the minutes and seconds, by means of an arm moved with a screw along the limb of the quadrant. His explanation of the inflection of a direct into a curvilineal motion, was read to the Society on the 23d May 1666.

On the 19th of September 1666, he laid before the Royal Society a model for rebuilding the city of London, which was destroyed by the great fire; but though his plan was not executed, he was appointed one of the surveyors under the act of parliament; a situation in which he realized a considerable sum of money, which was found after his death in a large iron chest, that appeared to have been shut up for 30 years. The irritable temper of our author now involved him in several quarrels, in all of which he conducted himself with impropriety. In our life of Hevelius, we have already given an account of his controversy with that astronomer respecting the comparative merits of plain and telescopic sights. In 1671, he attacked Newton's theory of light and colours; and in 1675 he had a warm dispute with Mr Oldenburg, the secretary to the Royal Society, in consequence of his pamphlet, entitled "A Description of Helioscopes, and some other Instruments, made by Robert Hooke," in which he complains that Oldenburg had not done him justice respecting his invention of pendulum watches. The dispute terminated by a declaration of the Royal Society, who took the part of their secretary. In 1676, he published his "Description of Helioscopes, and some other Instruments," a work which contains many curious inventions, some of which are described in anagrams. Upon the death of Oldenburg in 1677, Hooke was appointed to the vacant office of secretary; and while he held that situation, he published between 1679 and 1681 the seven numbers of the *Philosophical Collections*, which have always been regarded as a part of the Philosophical Transactions.

About this time the natural peevishness of his temper began to become quite intolerable: He claimed as his own the inventions and discoveries of every other person; and he became so reserved in communicating his own labours to the public, that though he read his Cutlerian lectures, and exhibited new inventions to the Royal Society, yet he never left any account of them to be entered in the registers. When the *Principia* appeared in 1686, he laid claim to the discovery of the doctrine of gravitation, a claim which was warmly resented by Sir Isaac Newton. Hooke, no doubt, had the merit of stating, that gravitation was the power which kept the planets in their orbits, and he even made some experiments to determine the law by which it was regulated; but what a vast interval is there between this conjecture, happy as it is, and the splendid discoveries of Newton!

In the year 1687 he suffered a severe loss by the death of his brother's daughter, Mrs Grace Hooke, who had lived several years with him; and the distress of his mind was still farther increased by a Chancery suit with Sir John Cutler respecting his salary. In 1691, Archbishop Tillotson employed him in contriving the plan of the hospital near Hoxton, founded by Robert Ash; and out of gratitude for his services, that distinguished prelate obtained for him the degree of M. D. When the Chancery suit with Sir John Cutler was determined in his favour in 1696, he was so overjoyed, that he left an account of his feelings in his diary, expressed in the following manner. "DOMSHLGISSA, that is, *Deo, optimo, maximo, sit honor, laus, gloria in sæcula sæculorum, Amen.*" "I was born on this day of July, 1635, and God hath given me a new birth; may I never forget his mercies to me! while he gives me breath may I praise him!" In order to induce him to complete some of his inventions, the Royal Society requested him in 1696, to repeat most of his experiments at their expence, but the infirm state of his health prevented him from complying with their request. During the two or three last years of his life he is said to have sat night and day at a table, so much engrossed with his inventions and studies, that he never undressed himself or went to bed. Emaciated with the gradual approach of old age, he died in Gresham College on the 3d March 1702, in the 87th year of his age, and was buried in St Helen's church, Bishopsgate street, his funeral being attended by all the members of the Royal Society who were then in London.

Besides the works which we have mentioned, he published in 1677 his *Lampas*, or *Descriptions of some mechanical improvements in lamps and water poises*.

The most important of Dr Hooke's inventions, was undoubtedly the method of regulating watches by the balance spring, which has since his time been carried to the highest perfection. Huygens has commonly been considered as the author of this invention, but there is no doubt that Hooke had invented it about 14 years before. The posthumous works of Dr Hooke, collected from his papers by Richard Waller, secretary to the Royal Society, with a life of the author prefixed, were published in 1705. Another life of Hooke was published in Ward's *Lives of the Gresham Professors*, p. 109. Lond. 1740. The papers which Hooke contributed to the Philosophical Transactions, will be found in volumes i. ii. iii. v. vi. ix. xvi. xvii. and xxii. of that work.

The following list of Dr Hooke's inventions is taken principally from a MS. of the late Dr Robinson, professor of natural philosophy in the university of Edinburgh.

1655. Hooke discovered that the barometer indicated changes in the atmosphere, and was connected with the weather. Before the year 1652 the same discovery was made by the Rev. Mr. Gregory of Drumoak. See our Life of JAMES GREGORY.

1655. Contrived the clockmakers' cutting engine.

1656. Contrived a 'scapement for the small vibrations of pendulums.

1656. Invented the spiral spring for regulating the vibrations of a watch balance.

1658. Contrived the Boilean or double barrelled air-pump.

1660. Used the conical pendulum for procuring a minute division of time.

1660. Explained capillary attraction by affinity.

1660. Found that the catenarian curve was the best form for an arch.

1663. Invented his marine barometer and sea gage, and also the method of supplying air to the diving bell.

1664. Invented a quadrant by reflexion, and a clock for registering the weather.

1664. Proposed the freezing of water in a fixed temperature; and in 1684 the boiling of water as another fixed point.

1664. Applied a screw for dividing astronomical instruments.

1665. Proposed to find the earth's parallax by means of a zenith telescope, also by observing the moon in distant places, and in a solar eclipse.

1666. Nov. 28. Invented the spirit level.

1668. Proposed his theory of combustion. See his *Micrographia* and *Lampas*.

1669. Proposed a pendulum, or a drop of water, as a standard measure. Proposed a camera obscura with a lamp.

1674. Invented the areometer.

1674. Tried the famous experiment with Newton on the inflexion of light.

1678. Proposed a steam engine on Newcomen's principle.

1679. Shewed that the path of a falling body compounded with the earth's motion is an ellipse.

1680. First observed the secondary vibrations of sounding bodies; that a glass touched with a fiddle bow threw water into waves at four points, and that the fundamental sound was accompanied with its harmonics.

1682. Observed the separability of heat and light by a glass plate.

1687. Observed the rapid propagation of sound through solid bodies.

Hooke appears also to have been the first who explained the rise of vapour by a dissolving power in the air, and who took a just view of the arrangement of iron filings round a magnet. See HEVELIUS and HUYGENS. ($\pi$)

HOOKER, RICHARD, an eminent English divine, was born at Heavitree, near Exeter, in the year 1553, or, according to Wood, in 1554. His parents, who were by no means in affluent circumstances, intended to educate him for some mechanical trade; but his schoolmaster at Exeter, having discovered his natural endowments and capacity for learning, prevailed with them to allow him to continue at school. His uncle, John Hooker, who was then chamberlain of the town, recommended him to Jewel, bishop of Salisbury, who, after examining into his merits, took him under his protection, and got him admitted into Corpus Christi College, Oxford, of which he was chosen fellow in 1577. Before this last period, however, Hooker had the misfortune to lose his patron; but his talents and excellent disposition soon procured him other valuable friends in Dr Cole, then president in his college, and Dr Sandys, bishop of London. The bishop placed so much confidence in Hooker's character, that he entrusted his own son to his care.

In 1577, Mr Hooker took his degree of M. A., and in the same year he was elected fellow of his college. In 1579, he was appointed deputy-professor of the Hebrew language in the university: but for some cause, which cannot now be ascertained, he and some others were expelled the college by the vice-president, to which, however, they were again restored in the course of two or three weeks. In 1581, he entered into orders, and was soon after appointed to preach at St Paul's Cross in London. Through the great simplicity of his character, he was, about the same time, entrapped into a foolish and unfortunate marriage with a woman who had neither beauty nor portion to recommend her, and who has been represented by Wood as "a silly clownish woman, and withal a mere Xantippe." In consequence of this imprudent step, he lost his fellowship, and was obliged to quit the university before he had obtained any preferment. He was therefore obliged to support himself as well as he could, until the latter end of the year 1584; when he was presented by John Cheney, Esq. to the rectory of Drayton-Beauchamp, in Buckinghamshire, where he led a most uncomfortable life with his wife Joan. In this situation he received a visit from his friend and pupil Sandys, in company with another pupil, Mr Cranmer, a grand-nephew of the celebrated Archbishop Cranmer. These young men found their learned and respected tutor in a common field, with a Horace in his hand, tending a small flock of sheep, in the absence of his servant, who had been called away to assist his mistress in some domestic business. When released from this duty, his friends accompanied him to his house, where they had an opportunity of witnessing the vexation and misery to which he was constantly subjected, from the churlish and capricious conduct of his wife. Upon their return to London, Mr Sandys acquainted his father with Hooker's deplorable situation, who took a warm interest in his concerns, and got him appointed master of the Temple, in 1585. Although this was a fine piece of preferment, Hooker soon discovered that London was not a place that suited his temper and disposition; and several circumstances conspired to excite in him the desire of obtaining the retirement of a country living. At the time when he was chosen master of the Temple, he got involved in a controversy with Travers, an afternoon lecturer there,—a man, it is said, of learning and good manners, but zealously attached to the Geneva government. This controversy led Hooker into a serious examination of the form and principles of church-government, which terminated in his celebrated work *Of the Laws of Ecclesiastical Polity*, the foundation and plan of which were laid while he was at the Temple. But in this residence he found himself incapable of carrying on the work to his own satisfaction; and he therefore entreated the archbishop, Whitgift, to remove him into some more quiet situation, in a letter which exhibits an interesting picture of that union of piety, simplicity, the love of learning and retirement, which formed the predominant feature of his character. "My lord," says he, "when I lost the freedom of my cell, which was my college, yet I found some degree of it in my quiet country parsonage. But I am weary of the noise and oppositions of this place; and indeed God and nature did not intend me for contentions, but for study and quietness. And, my lord, my particular contests here with Mr Travers have proved the more unpleasant to me, because I believe him to be a good man; and that belief hath occasioned me to examine mine own conscience concerning his opinions. And to satisfy that, I have consulted the Holy Scriptures, and other laws, both human and divine, whether the conscience of him, and others of his judgment, ought to be so far complied with by us, as to alter our frame of church-government, our manner of God's worship, our praising and praying to him, and our established ceremonies, as often as their tender consciences shall require us. And in this examination I have not only satisfied myself, but have begun a treatise, in which I intend the satisfaction of others, by a demonstration of the reasonableness of our laws of ecclesiastical polity. But, my lord, I shall never be able to finish what I have begun, unless I be removed into some quiet parsonage, where I may see God's blessings spring out of my mother earth, and eat my own bread in peace and privacy; a place, where I may without disturbance meditate my approaching mortality, and that great account, which all flesh must give at the last day to the God of all spirits."

In consequence of this application, he was presented, in 1591, to the rectory of Boscomb, in Wiltshire; and in the same year, he obtained other valuable preferments in the cathedral of Salisbury. At Boscomb he finished four books of his *Ecclesiastical Polity*, which were entered at Stationer's hall in the month of March 1592, but not printed till 1594. In the following year he quitted Boscomb, and was presented by Queen Elizabeth to the rectory of Bishop's Bourne, in Kent, where he resided during the remainder of his life, discharging the duties of his office in the most conscientious and exemplary manner. In this place he composed the fifth book of his great work, which was dedicated to the archbishop, and published by itself in 1597. He also finished the 6th, 7th, and 8th books, but did not live to publish them; and it has been much disputed whether we have these books genuine as he left them. In the year 1600, he caught a severe cold, in a passage between London and Gravesend, which produced a lingering and painful illness, that at length put a period to his life, in the 47th year of his age. He died on the 2d of November 1600. Notwithstanding the severity of his indisposition, he persevered in his studies to the last. A few days before his death his house was robbed. When informed of that circumstance, he enquired whether his books and written papers were safe; and being answered that they were, "then," said he, "it matters not, for no other loss can trouble me."

The personal character of Hooker may be gathered from the preceding narrative of his life. As an author, the church is indebted to him for the most profound and ingenious defence of ecclesiastical establishments that has ever appeared. His treatise on *Ecclesiastical Polity*, indeed, has been admired both at home and abroad, as a work of deep and extensive research, and of acute and sound reasoning: and the author has been universally distinguished by the honourable titles of "the judicious," and "the learned." Of this valuable work, Pope Clement VIII. is reported to have said, that "there were in it such seeds of eternity as will continue till the last fire shall devour all learning." When King James I. ascended the throne of England, he is said to have asked Archbishop Whitgift for his friend Mr Hooker; and being answered that he had died a year before the queen, who expressed great concern when she received the news, he replied, "And I receive it with no less, as I shall want the desired happiness of seeing and discoursing with that man, from whose books of church polity I have received such satisfaction." He afterwards added, "though many others write well, yet in the next age they will be forgotten; but doubtless, there is in every page of Mr Hooker's book the picture of a divine soul; such pictures of truth and reason, and drawn in so sacred colours, that they shall never fade, but give an immortal memory to the author."

Besides the eight books of *Ecclesiastical Polity*, and his answer to Travers's *Supplication*, Hooker left some sermons, which were collected and published with his works in folio. An octavo edition has also been printed at Oxford. (z)

HORACE, QUINTUS HORATIUS FLACCUS, one of the most celebrated of the Roman poets, was born at Venusium, a town in the confines of Apulia and Lucania, in the consulship of Aurelius Cotta and Manlius Torquatus. His father was the son of a freedman, and followed the employment of a tax-gatherer. This was the poet's own account, and most likely to be true. Some of his enemies, however, reproached him with his father having been a fishmonger (*Salsamentarius*,) and one of them said to him, *Quoties ego vidi patrem tuum bracchio se immungentem.* His father, however, though of humble origin, appears to have been a man of liberal sentiments, and to have given his son an excellent education, as the son has recorded in these lines, so honourable to the memory of both:

> "Causa fuit pater his:* qui macro pauper agello
> Noluit in Flavi ludum me mittere, magni
> Quo pueri magnis è centurionibus orti
> Lævo suspensi loculos tabulamque lacerto,
> Ibant octonis referentes Idibus æra:
> Sed puerum est ausus Romam potare docendum,
> Artes, quas doceat quivis eques, atque senator
> Semet prognatos: vestem servosque sequentes
> In magno ut populo si quis vidisset; avita
> Ex re præberi sumptus mihi crederet illos.
> Ipse mihi custos incorruptissimus omnes
> Circum doctores aderat, quid multa? pudicum
> (Qui primus virtutis honos) servavit ab omni
> Non solum facto, verum opprobrio quoque turpi.
> * * * * *
> *Nil me pœniteat sanum patris hujus.*"
>
> Sat. vi. lib. 1.

At the age of eighteen, Horace was sent to Athens, for the purpose of finishing his education, by the study of philosophy and Greek literature. Whilst he was in that city, Marcus Brutus, in his way to Macedonia, stopped at the university, and, being pleased with Horace, took him along with him on his journey. Brutus afterwards entrusted a legion to his care as military tribune. As the poet, in his writings, freely confesses, that he had no great genius for fighting, it may be suspected, that it was by his wit and companionable talents that he had ingratiated himself with Brutus. At the battle of Philippi, he describes himself, with some humour as throwing away his shield, to be disencumbered in his flight. By the victory of the opposite party his property was forfeited, but his life was spared. In his indigence he wrote verses, and so recommended himself to Virgil and Varius, that, with the generosity of true poets, they recommended him to Mæcenas. At the first interview with that noble patron, as he tells us in the satire already quoted, he behaved with diffidence, and simply told Mæcenas what he was. The nobleman, as was his custom, said little in reply, and did not send for him again till nine months after, when he admitted him among the number of his friends, and made him easy in his circumstances. Horace proved so agreeable to Mæcenas, that he made him his familiar companion, in which capacity he accompanied him to Brandusium, in that journey which the poet has so agreeably described in verse. He also introduced him to Augustus, who delighted in his society, and used to call him *homuncio lepidissimus*. When seated between Virgil and Horace, the emperor used to say, that he was between sighs and tears; alluding to the uneasy respiration which afflicted Virgil from a chest complaint, and to Horace's tender eyes. Horace was certainly a courtier, and he did not lay on his flattery in faint colours; nor does he seem to have troubled his patrons with any recurrence to those maxims of public liberty, which he must have learned with Brutus, and which had led him into the field of Philippi; but, on the other hand, he makes allusion to great republican names with the spirit of a Roman and of a poet; and he lived among the great with *personal* independence, for he declined the post offered him by Augustus, of being his private secretary.

The incidents of his life are few. His person is described as short and inclined to corpulence, and his temper as easy and obliging. He passed his time between Rome, his Tiburtine or Sabine villa, and the soft climate of Tarentum, to which he fled in winter. Though an Epicurean enjoyer both of society and of sensual pleasures, his writings breathe a fondness for rural retirement, and he seems often to have returned from the satiety of vice to the calm of virtue and repose. He died in his 59th year, and was interred near his patron Mæcenas. Horace is the only one of the Latin lyric poets who has come down to posterity; a circumstance for which the judgment of Quinctilian may console us, who assures us, that they were scarcely worthy of perusal. In Horace have been supposed to be united, if not individually surpassed, the gaiety of Anacreon, the majesty of Alcæus, and the fire of Pindar. We must leave it to the lovers of voluptuous literature to decide, whether the revelling of the Teian bard possess not a lighter grace of ecstacy than that of the Roman? The soul of pleasure is in both; but Horace's moral reflections (Epicurean as his philosophy was) are often like a drapery to his luxuriant images, that encumbers their joyousness without communicating decorum. In the parallel with Pindar, he presents a clear and rapid brilliancy of thought, more pleasing, if less astonishing, than the vague and obscure sublime of the Theban poet, as well as a richer variety in his subjects. He may be called, perhaps without a rival, the master of expression; and such is the harmony and diction of his odes, that an apt quotation from them always sparkles like a gem, when it illustrates the most eloquently expressed thought in the page of any language. Of all poets he is the most frequently quoted. To the merits of style, harmony, and fancy, must be added his knowledge of human nature, and of the principles of human manners, exhibited in that part of his writings where the tone of fancy and poetical diction is purposely relaxed; in his satires, to wit, where we take him to our bosoms for his good humour, and where his good sense instructs us in the language of friendship. His epistle to Pisos has, perhaps, been too much considered as an attempt on his part to give a perceptive theory of the whole art of poetry. It is, in fact, only an epistle upon the subject, in which his design is evidently desultory. Horace knew poetry too well, to think of submitting so ethereal a subject to the trammels of systematic theory; and it is not his fault, if the world has been since annoyed with sickening attempts to teach the art of inspiration. The infallibility of all his tenets of taste it is not our business here either to impeach or support; but, in a general view, it must be confessed, that his maxims, though misapplied by pedants to narrow the range of dramatic genius, have, with reference to all that was then known in that species of poetry, a most respectable weight and felicity. HORN, a musical wind instrument, which, whether of the short kind, called a bugle horn, or the long coiled kind, called a French horn, has a scale of intervals alike defective, and similar to that of the common Trumpet, which see. The supplying of chromatic notes to the scale of the French horn, so as to render it an instrument of general use in an orchestra, is said to have been first attempted in the beginning of the 18th century, in Germany; and since 1740, Messrs. Messings, Spandau, Porto, Leanders, Petrides, &c. have succeeded here in different degrees, in supplying all the requisite notes to the horn, by means of the hand, or a turned block of wood thrust into the mouth of the instrument, so as to alter the length of the sounding part of the tube, in the requisite degrees, during performance.

The late Mr Charles Clagget, as we have explained in our article Chromatic *French Horn*, attempted to accomplish the same thing, by means of two attached tubes, one half a tone higher than the other, either of which the performer could blow at pleasure; but it did not succeed, so as to continue in use. In 1810, Mr William Clare in-

* Speaking of the better traits of his character.

vented and transferred to Mr Perceval, opposite St James's Palace, the patent for a polyphonian French horn, whose scale is rendered complete by means of finger-holes in its sides, and keys like those of a flute. (ϛ)

HORN, Cape. See Fuego.

HORN-Pressing, is the art of moulding or forming toys and various articles in horn or tortoise-shell. These animal substances are capable of being so softened by the application of a moderate heat, that they can be moulded by pressure into any required shape, and the surface may be imprinted with any design in the sharpest and most delicate relief. Another valuable property is, that pieces may be made to adhere firmly together without any cement. In the article Button-*Making*, we have already given a description of the method of pressing horn buttons, by means of iron moulds and a strong vice. The same machine, and similar moulds, are used for knife-handles or other simple articles; but for making hollow articles, such as snuff-boxes, tooth-pick cases, powder-flasks, tubes of opera-glasses, ink-horns, &c. a screw-press is used. The process is extremely simple: The horn or tortoise-shell is boiled in water until it becomes softened, and is then put into moulds of iron or brass, made in two or more pieces, and with cavities between them to correspond with the article which is to be fabricated, and, with all its intended ornaments, engraved in the interior surface of the mould. This mould being made hot, the horn or shell is put between its two halves, and the mould being put in a small screw-press, the halves are forced together to imprint the horn, and press it into the cavity of the mould. If the article has any considerable relief, this cannot be done at one heat, and therefore the press, with the moulds in it, is put into a copper, and boiled still longer: it is then taken out, and, by a lever applied to the screw, it is screwed tighter, so as at length to obtain the impression desired. When a single piece of horn or tortoise-shell is not sufficiently large to fill the mould, two or more pieces are put together: they are cut to fit to each other with a proper degree of overlap, and when sufficiently softened by boiling in water, the surfaces are forcibly pressed together, and they will thus be united as firmly as if they were originally in one piece. The screw-press employed for this business is very simple, being only an iron frame, with a screw through the top of it; and, for the convenience of putting it in and out of the boiler or copper, a small tackle of pulleys is fixed just over the copper, and by the side of it is a block of stone, with a hole or cavity in it large enough to receive the press, and hold it firmly upright, whilst a lever or wrench is applied to the screw to turn it round and produce the pressure, which being done, it is again returned into the boiler. To obviate the inconvenience of thus lifting the press in and out of the boiler, Messrs Poltzappfell and Deyerlin of London have made the machine represented in Figs. 1. and 2. of the Plate. Plate CCXCIX. Fig. 1. being a section, and Fig. 2. an elevation, AA is a box or case of cast iron; B, a boiler or copper to contain the water; and C, the grate for the fire, which is to be placed beneath it to heat the water; E is the flue or chimney, at which the smoke passes off; FFG is a press, made very strong, of cast iron, and capable of being drawn up out of the water, or let down into it at pleasure, by means of racks *a*, *a* at each side, which are actuated by pinions *d*, *d*; the axes *o* of these pinions extend across the machine, and have each a wheel N at the end; and these wheels are moved at the same time by two arms or endless screws, cut upon an axis, which extends from one to the other, and is turned by the handle H: the press is guided in this ascent or descent by grooves in the side of the boiler. When raised up out of the water, the moulds, with the horn or tortoise-shell between them, are put beneath the presser I, and a severe pressure is produced by turning the wheel K. This wheel has an endless screw R upon its axis, which works the teeth of a large wheel L, fixed on the top of the screw P. The screw is received into a female screw formed within the box or presser I, which is guided and prevented from turning round by the cross bar *e e*, through which the presser is fitted; by this means, when the screw P is turned round by the wheel L and endless screw, the horn or tortoise-shell is pressed between the moulds; the press is then lowered again into the water of the boiler, in order to be still farther softened by the boiling; but when the press is down in the boiler, the screw can be screwed tighter by turning the wheel K until the desired impression is obtained. By turning the handle N, the press is then raised up out of the boiler, and by turning back the wheel K, the pressure is released, and the moulds can be removed.

The Figures X, Y and Z represent a pair of moulds proper for forming a cylindrical snuff-box: X is the internal mould for the box, into the bottom of which a piece of shell, softened by boiling, and cut round, is first placed; and round the inside a long slip is curled, the ends being made to lap over with a proper joint. The external mould Y is then put into the cavity of the horn, and is forcibly pressed by the screw so as to give the horn the shape of Y when it is withdrawn from the mould: a similar mould is used for making the lid of the box. Small boxes, and those which are slightly raised, can be made from one single piece without joining; also tooth-pick cases and similar articles.

The Chinese are famous for making lanterns of horn very thin and transparent. We are informed, in the *Annales des Arts*, that they employ the same methods as we do of effecting the joinings by softening the horn in hot water, but that they use a long beam or lever, for making the pressure. This method is for making up the leaves of horn from small pieces; but as the boiling would disfigure these leaves, they are united together to form the lanterns, by warming them at the fire, and pressing the edges of them together by hot pincers, made flat on the inside; by this means the joints are so perfect that they can scarcely be perceived. See a translation of this paper in the *Repertory of Arts*, 2d Series, vol. xxix. An account of the manufacture of Chinese lanterns will be found in the *Memoires des Sçavans Etrangers*, tom. ii. p. 350, in a Memoir by M. D'Incarville. (J. F.)

HORNS. See Anatomy, *Comparative*.

# HOROLOGY.*

Horology is the art of constructing machines for measuring time. The word is derived from the Greek Ὡρολογιον, (through the Latin *horologium*,) compounded of ὡρα, *an hour*, and λεγω, *to read* or *point out*; hence ὡρολογιον, a machine for indicating the hours of the day.

Long before sun-dials were invented, clepsydræ, or

* The Editor is indebted to Mr Thomas Reid for the following article on Horology.

water clocks, had been made in the most remote periods of antiquity, and were used in Asia, China, India, Chaldea, Egypt, and Greece, where Plato introduced them. Julius Cæsar found them even in Britain, when he carried his arms thither; and it was by them he observed, that the nights in this climate were shorter than those in Italy: (See his *Commentaries*, lib. v. xiii.) Toothed wheels, although known a considerable time before, were first applied to clepsydræ by Ctesibius, a native of Alexandria, who lived 140 years before the Christian era. At what time, or by whom, was invented the clock with toothed wheels, crown wheel 'scapement, and the regulator in the form of a cross suspended by a cord, with two weights to shift on it, can now only be guessed at, as no positive information on this subject has been handed down to us. It was this kind of clock, a large turret one, which Charles V. king of France, surnamed the Wise, caused to be made at Paris by Henry Vick, who was sent for from Germany for the express purpose, and which was put up in the tower of his palace about the year 1370. Julien le Roy, who had seen this clock, has given some account of it in his edition of Sully's *Regle Artificielle du Temps*, Paris 1737: (See Plate CCC. Fig. 1. and the Description of the Plates at the end of the volume.) Before a clock could be brought even to the state of the one made by Vick, there must have been many alterations and progressive improvements upon that which had first been projected, so that it must have been invented at least two or three centuries before Vick's time. As the same word for a sun-dial among the Greeks and Romans was also that for a clock, disputes have arisen, whether the *horologia* of Pacificus and of Gerbert were sun-dials or clocks. Father Alexander asserts that the horologium of Gerbert was a clock; while Hamberger supposes it to have been a sun-dial, from the pole-star having been employed in setting it. Pacificus was archdeacon of Verona about the year 850. Gerbert was pope, under the name of Silvester II. and made his clock at Magdeburg, about the year 996.

Richard of Walingford, abbot of St Albans in England, who flourished in 1326, by a miracle of art constructed a clock, which had not its equal in all Europe, according to the testimony of Gesner. Leland too, an old English author, informs us, that it was a clock which shewed the course of the sun, moon, and stars, and the rise and fall of the tides; that it continued to go in his own time, which was about the latter end of Henry the Seventh's reign; and that, according to tradition, this famous piece of mechanism was called *Albion* by the inventor.

"In 1382," says Father Alexander, "the Duke of Burgundy ordered to be taken away from the city of Courtray, a clock which struck the hours, and which was one of the best known at that time, either on this side or beyond seas, and made it be brought to Dijon, his capital, where it still is in the tower of Notre Dame. These are the three most ancient clocks that I find, after that of Gerbert."

"We know no person," continues this author, "more ancient, and to whom we can more justly attribute the invention of clocks with toothed wheels, than to Gerbert. He was born in Auvergne, and was a monk in the abbey of St Gerard d'Orillac, of the order of Saint Bennet. His abbot sent him into Spain, where he learned astrology and the mathematics, in which he became so great a master, that, in an age when these sciences were little known, he passed for a magician,* as well as the Abbot Trithemius. From Spain he came to Rome, where he received the abbacy of Bobio in Italy, founded by Saint Columbus; but the poor state of its funds compelled him to return to France. The reputation of his learning and uncommon genius, induced Adalberon, Archbishop of Rheims, to establish him, in 970, as rector of the schools there, and at the same time to make him his private secretary. It was near the end of the tenth century, about the year 996, when he made at Magdeburg this clock, so wonderful and surprising, *by means of weights and wheels.* He was Archbishop of Rheims in 992, a situation which he held during three years, then archbishop of Ravenna in 997, and at last sovereign pontiff, under the name of Silvester II. in 999; and he died at the beginning of the fifth year of his pontificate, in 1003." The clock constructed by Gerbert seems to have been made after he left Rheims, and before his appointment to Ravenna; and it is highly probable, that this was the period when clock-making was introduced into Germany.

"William Marlot," continues the same author, "to show how wonderful this piece of work was, makes use of an expression which can hardly be suffered in our language: *Admirabile horologium fabricavit, per instrumentum diabolica arte inventum.*"

Since toothed wheels had been known above 1300 years before Gerbert is said to have made his horologium, and above 1100 after they had been applied to the clepsydra, and as they were also sculptured on Trajan's column at Rome, where they are still to be seen, there seems to be nothing unaccountable in Gerbert's having fallen on the way of applying wheels to make a clock different from the clepsydræ, which had been long in use. Besides, Father Alexander seems to have investigated the history of horology more profoundly and indefatigably than Hamberger; and Gerbert may have made use of the pole-star, for other purposes than merely to set a sun-dial by it, and probably for the purpose of drawing a meridian line, in order to regulate his clock. If it were a sun-dial, as some suppose, why does Marlot, who wrote at Rheims in 1679, consider it as such a wonder, since it appears from our *History of* DIALLING, that dials were well known, and in common use, 1600 years before Gerbert's time? Hamberger, however, admits, that the clock was invented in the eleventh century; and he thinks it probable, that we are indebted to the Saracens for it. Now Gerbert's clock was made near the commencement of the same century. The college in Spain, where he had been instructed, had Arabians or Saracens among its professors, and was at that time the only place in Europe where any learning or science was to be found.

The argument against Gerbert's horologium being a clock, in our acceptation of the word, is, that he made use of the pole star, as if to set a sun-dial by it; and yet we have no positive information that it was a sun-dial. Berthoud admits, that such a clock as Vick's could not have been a new invention; and he thinks, "that the different parts which compose the balance clock, have only been made after a long train of research and of time, which supposes the highest antiquity for the successive discoveries, and that clocks were not known in France till the middle of the 14th century."

The art of horology might be going slowly on in Germany, though the balance clock was unknown in France till 1370, previous to which Vick had been sent for. Had this not taken place, it might perhaps have remained still longer unknown. It must be allowed, that there is something inconsistent in Father Alexander's argument, for giving the clock to Gerbert, and refusing it to Pacificus,

* It may have been for a crime of this kind that he was afterwards banished from France.

"because it was not known in France till 250 years after. The discovery was of too great utility not to be spread abroad, particularly in monasteries, where it was so much required to regulate the office of the night. In the famous monastery of Cluny, however, the sacristan, in 1108, went out to see the stars, in order to know the time when to awaken the monks to prayer." In the early stage of the art very few clocks could have been made, and those which were constructed could not be of much use.

"As all arts are at first imperfect," says Hamberger, "it is observed of these clocks, that they sometimes deceived; and hence in the *Ordo Cluniacensis Bernardi Mon.* the person who regulated the clock is ordered, in case it should go wrong, 'ut notet in cereo, et in cursu stellarum vel etiam lunæ, ut fratres surgere faciat ad horam competentem.' The same admonition is given in the *Constitutiones Hirsaugiensis*." From what is said here, it may be inferred, that even those who had clocks in the earliest periods, could not place much dependance on their time-keeping; and with great probability we may suppose, that many a palace and monastery might continue a long time unprovided with such a machine. It was near the end of the 15th century before they came to be in use among private persons.

The art of clockmaking seems to have been introduced into Europe by some of the Romish clergy. They were, in general, especially the higher orders, possessed of wealth, time, and leisure, to cultivate such of the arts and sciences as were then to be attained; and if the art of horology did not originate with them, they certainly were among the first who did every thing in their power to promote and encourage it. Time measuring being so desirable for the regulation of the stated services required of the church, which took place at all hours of the day and night, their attention was naturally called to a subject in which they were so much interested.

Those who wish for more information on the origin of clocks, are referred to the following works. *The Artificial Clockmaker*, by William Derham, D. D. London, 1698. *Traité general des Horloges*, par le R. P. Dom. Jacque Alexandre, Religieux Benedictin de la congregation de Saint Maur. A Paris, 1794. A Dissertation by Hamberger in Beckmann's *History of Inventions*, vol. iii. Lond. 1797. *Histoire de la Mesure du Temps par les Horloges*, par Ferdinand Berthoud, mechanicien de la marine, &c. &c. A Paris, 1802. This last is a very interesting work for an amateur in horology, and was the result of seven years labour, when the author was at a very advanced period of life. To these may be added *Histoire de l'Astronomie Moderne*, tom. i. p. 60, edition de 1785, and *Histoire de l'Astronomie Ancienne. Eclaircissemens*, liv. iv. § 34. liv. ix. § 5. Vitruvius's *Architecture*. Pollius Vitruvius lived 40 years before Christ, and was architect to Augustus. In a triumph of Pompey, among the spoils brought from the East, was a water clock, the case of which was strung round with pearls. *Pliny*, lib. xxxvii. cap. i. *Memoires de l'Academie des Inscriptions*, tom. xx. p. 448.

It would be a waste of time to describe the nature of wheels and pinions, as this kind of machinery is now so generally known. It may be sufficient to remark, that a clock or a watch movement is an assemblage of wheels and pinions, contained in a frame of two brass plates, connected by means of pillars, the first or great wheel of which, in an eight day clock movement, has concentric with it a cylindrical barrel, having a spiral groove cut on it. To this cylinder is attached one end of a cord, which is wrapped round in the groove, for any determined number of turns, and to the other end of the cord is hung a weight, which constitutes a power or force to set the wheels in motion. Their time of continuing in motion will depend on the height through which the weight has to descend, on the number of teeth in the first or great wheel, and on the number of teeth or leaves of the pinion upon which this wheel acts, &c. The wheels in spring clocks and in watches are urged on by the force of a spiral spring, contained in a hollow cylindrical barrel or box, to which one end of a cord or chain is fixed, and lapping it round the barrel for several turns outside; the other end is fixed to the bottom of a solid, shaped like the frustum of a cone, known by the name of the *fusee*, having a spiral groove cut on it; on the bottom of this cone, or fusee, the first or great wheel is put. The arbor on which the spring barrel turns, is so fixed in the frame, that it cannot turn when the fusee is winding up; the inner end of the spring hooks on to the barrel arbor, and the outer end hooks to the inside of the barrel. Now if the fusee is turned round in the proper direction, it will take on the cord or chain, and consequently take it off from the barrel. This bends up the spring; and if the fusee and great wheel are left to themselves, the force exerted by the spring in the barrel to unbend itself, will make the barrel turn in a contrary direction to that by which it was bent up. This force of the spring unbending itself, being communicated to the wheels, will set them in motion, and they will move with considerable velocity. Their time of continuing in motion will depend on the number of turns of the spiral groove on the fusee, the number of teeth in the first or great wheel, and on the number of leaves in the pinion upon which the great wheel acts, &c. The wheels in any sort of movement, when at liberty or free to turn, and when impelled by a force, whether it is that of a weight, or of a spring, would soon allow this force to terminate; for, as the action of the force is constant from its first commencement, the wheels would be greatly accelerated in their course, and it would be an improper machine to register time or its parts. The necessity of checking this acceleration, and making the wheels move with an uniform motion, gave rise to the invention of the *escapement*, or *'scapement*, as it is commonly called. To effect this, an alternate motion was necessary, which required no small effort of human ingenuity to produce.

## CHAP. I.

### *On the Escapement, or 'Scapement.*

The escapement is that part of a clock or watch connected with the beats which we hear them give; and these beats are the effects of the moving power, carried forward by means of the wheels in the movement to the last one, which is called the *swing wheel* in a pendulum clock, and the *balance wheel* in a watch. The teeth of this wheel act on the pallets or verge, which are of various shapes, and which form the most essential part in a 'scapement; the drop from each tooth of the swing or balance wheels, on their respective pallets, giving one beat or impulse to the pendulum or balance, in order to keep up or maintain their motion; and were it not for the pallets which alternately stop the teeth of the swing or balance wheels, the motive force would have no check. Hence it is, that, by this mechanism of the 'scapement, the wheels in the movement are prevented from having their revolutions accelerated, which would take place to such a degree, as to make the machine run down in a minute or two; whereas, from the resistance opposed by the pallets, it is kept going for twenty-four or thirty hours, for a week or a month, or even for twelve months. In the clocks or watches, however, which as a matter of curiosity have been made to go so long, it was not possible to have an accurate measure of time.

No part of a clock or watch requires so much skill and judgment in the contrivance of it, and so much care and nicety in its execution, as that of the 'scapement; none of the 'scapements of the present day require this more than the ancient crown wheel and verge 'scapement, which, when nicely executed, upon the proper principle, does extremely well for a common pocket watch. But this is a thing hardly now to be met with. From the time of Dr Hooke, and during the last century, many ingenious contrivances for 'scapements were suggested; but the number of them adopted in practice is very limited. The crown wheel and verge 'scapement is represented in Plate CCC. Fig. 2, where V is the verge, and C the crown wheel, *p*, *p* the pallets, and B B the balance. It is the oldest that is known, and must have been the only one used in clocks, for several centuries, previous to the middle of the seventeenth, or towards the end of it. Although it has been so long in use, and so well known to every clock and watch-maker, that its merits are now overlooked, and held in little estimation, yet, if it is duly considered, it will be found to have been a very masterly and ingenious device. The crown wheel and verge are of such an odd shape, that they resemble nothing that is familiar to us. Yet some ancient artist had contrived it for the purpose (and it certainly was an ingenious thought) to give an alternate motion to a plain wheel, or cross, which he had suspended from the upper end of its axis by a string, or which at first might rest on the lower end of the axis or *foot pivot*. This plain wheel was like the fly of our common kitchen jack. In place of this circular rim, or plain wheel on the axis, there were some of them that had two arms upon it, forming something like a cross; on these were made a sort of notches, concentric to the axis, in which were hung a small weight on each arm, which, by shifting more or less from the centre, the clock was made to go slow or fast. From the weightiness of this kind of balance, and the rude execution of the work, the friction on the end of the foot pivot would be so great, that it is probable there was some difficulty to make the clock keep going for any length of time. Recourse was then had to suspend the balance by a small cord, so that the end of the lower pivot should not rest on the foot of the potence. This ingenious idea has in modern times been adopted both by Berthoud and Le Roy, who have had the balances in some of their marine time-keepers suspended by a very small wire, or a very delicate piece of watch pendulum spring wire. The mechanism of the movement of these old clocks is exactly the same as has been frequently made for an alarm. To construct this, and apply it to a clock, there was hardly a step to go; and therefore in all probability the invention of the alarm part took place before that of the striking part, though some have thought otherwise. The contrivance of the striking part was a more complex process, and less likely to take place.* The alarm-clock is represented in Plate CCC. Fig. 3.

This opinion is strongly corroborated by the observations of Hamberger in Beckmann's *History of Inventions*. "These horologia," he remarks, "not only pointed out the hours by an index, but emitted also a sound. This we learn from *Primaria Instituta Canonicorum Præmonstratentium*, where it is ordered that the sacristan should regulate the horologium, and make it sound before matins to awaken him. I dare not, however, venture thence to infer, that these machines announced the number of the hour by their sound, as they seem only to have given an alarm at the time of getting up from bed. I have indeed never yet found a passage where it is mentioned that the number of the hour was expressed by them; and when we read of their emitting a sound, we are to understand, that it was for the purpose of awakening the sacristan to prayers. The expression *horologium cecidit*, which occurs frequently in the before-quoted writers, I consider as allusive to this sounding of the machine. Du Fresne, in my opinion, under the word *Horologium*, conceives wrong the expression *de ponderibus in imum delapsis*, because the machine was then at rest, and could raise neither the sacristan or any one else, whose business it was to beat the *scilla*."

When an alarm is set off, the weight, which is the moving force of it, very soon falls to the bottom, and then the alarm ceases.

In attempting to make the first 'scapement, there can be little doubt that something of the circular or cylindrical kind was contrived, and the only thing which could give it an alternate motion, was either a spiral spring or a pendulum; but these things being then unknown, the clockmaker was obliged to seek after other methods, and at last produced the crown wheel and verge 'scapement. How came it that means so complicated were fallen on, when those which were more simple and better were over-looked?

It is a very singular circumstance, that a small ball or weight, when suspended by a slender thread, and drawn a little aside from the perpendicular, on being let go, continues to vibrate for a considerable time, and with the utmost regularity. Many things in domestic life were hung up or suspended by strings, and were every day seen or observed; yet what a long time elapsed before any thing of this kind was ever thought of, or applied to regulate the motion of a clock! It is said that Galileo took his idea of a pendulum from the motion of a lamp, suspended from the roof or ceiling of a church, which had been accidentally set a vibrating. He used the simple pendulum in his astronomical observations, long before it was applied to a clock. Some of the earlier astronomers, as well as Galileo, used a common string and ball, which they made to vibrate a little while, during the time of an observation of any of the heavenly bodies. Yet even these astronomers did not think of its application to clocks. Some watch-finishers, when their watch is finished, for want of a pendulum clock, regulate it by means of a ball and string, which will answer very well, by taking 50 vibrations of a pendulum's length for seconds, in the same time that the wheel ought to make one revolution.

As gravitation is the principle on which the pendulum is founded, it cannot properly be considered as an invention, as some have called it, whatever name may be given to it when applied to regulate the motion of a clock. The pendulum having before this been long known in its simple state, and used as a sort of time measurer, it was no wonder that the idea of applying it to a clock was entertained by several persons nearly about the same period. The movement of the old balance clocks was not adapted for the application of the pendulum, so as to give motion to it; the wheels in it were all flat ones except the crown wheel, and no other 'scapement at this time was known but that of the crown wheel and verge; so that, without considerable difficulty and invention, the pendulum could not well be ap-

* In many parts of India, where public clocks are unknown at this day, they strike the hours upon a plate of silver, or silver alloyed with another metal, of a lenticular form, about 18 inches in diameter. It is hung on a frame by a doubled string; and when the hour is pointed out, either by their sand-glasses, clepsydræ, or water-dropping instruments, which they sometimes use, they strike with a wooden hammer on the middle of the circular plate, and thus indicate, by the number of blows, the hour of the day. The sound which is produced is strong, clear, and pleasant. This contrivance is used in many of the towns and camps throughout India.

plied to this construction of a clock movement. The pocket watch had been made a considerable time before this, and the construction of its movement, which had a contrate wheel in it, would naturally lead them to that of one which would adapt itself to the motion of a pendulum, as by means of the contrate wheel the crown wheel could be made to stand in a vertical position; whereas, in the old balance clocks, the position was horizontal. Galileo seems early to have discovered the properties of the pendulum, and the investigation was prosecuted with great success by Huygens. The son of Galileo applied the pendulum to a clock at Venice in the year 1649; but to what sort of a movement we cannot pretend to say, though we suspect, from that want of success which seems to have attended his trials, that he had not adopted the contrate wheel movement, already mentioned, as the most proper for it. We know that Huygens made use of this sort of movement, as the only one fit to be regulated by the motion of the pendulum, which he had also applied. Of late, another candidate for the application of the pendulum to a clock has been brought forward by such respectable authority, that leaves little or no room to doubt of its authenticity. Mr Grignion informs us, "that a clock was made in 1642, by Richard Harris of London, for the Church of St Paul's, Covent Garden, and that this clock had a pendulum to it."

It appears, from unquestionable evidence, that Galileo, mathematician to the Grand Duke of Tuscany, first discovered the properties of the pendulum, used it in his astronomical observations, and wrote a tract explaining the principles of it. This tract was translated from the Italian into French at Paris, printed in 1639 in a duodecimo volume, and sold by Pierre Ricolet. He intended to apply it to a clock, but this he never put into execution. Father Alexander says, "that they had nothing better than the balance clocks in France until the year 1660."

The application of the pendulum to a clock, and of the spiral form of a pendulum spring to the balance of a watch, were the greatest improvements that could possibly have been made in the machinery of time measuring, and they both happened to take place nearly about the same period.

Notwithstanding the application of the pendulum, and the ingenious contrivance of cycloidal cheeks by Huygens, in order to make the long and short vibrations be performed in nearly as equal time as possible, yet the clock did not keep time with that correctness which was expected: This arose from the great extent of the arc of vibration, the lightness of the pendulum ball, the great *dominion* which the clock had over the pendulum, and the bad effects produced by the cycloidal cheeks, which, however excellent in theory, were never found useful in practice. See Plate CCC. Fig. 4. where a front view of the cycloidal cheeks is represented in Fig. A. This led artists and amateurs of the profession to think of farther means of improvement; accordingly, about the year 1680, a clock was made by W. Clement, a clock-maker in London, having, in place of the crown-wheel and verge 'scapement, a 'scapement which was nearly the same as the common recoiling 'scapement of the present day. The swing-wheel, S W, was flat, having a sort of rachet or saw-like teeth: and the pallets, P P, had remote resemblance to the head of an anchor, by which it acquired at that time the name of the *anchor 'scapement*. See Fig. 5. The ball of the pendulum was made much heavier than what had formerly been adopted, the arc of vibration much shorter, and the motive force much less. From the excellent time-keeping of the clock, this was found to be a great improvement, and hence this 'scapement was afterwards generally practised. It passed into Holland and Germany, and was hardly known in France until the year 1695. See *Histoire de la Mesure du Temps*, tom. i. p. 100.

At the time when this clock of Clement's appeared, Dr Hooke claimed the invention of it as his, and affirmed, that after the great fire of London, in 1666, he had shewn to the Royal Society a clock with this very 'scapement. "Considering," says Sully, in his *Histoire des Echappemens*, "the genius, and the great number of fine discoveries of this excellent man, I see no room to doubt that he was the first inventor of it." The pendulum with this 'scapement had received the name of the *royal pendulum*.

The *dead-beat* 'scapement of Graham's next succeeded, which was invented some time after the beginning of the eighteenth century, and has continued to be that which is generally used in regulators, or astronomical clocks, with a very few exceptions. See Fig. 6. About ten or fifteen years afterwards, it came to be known in France, and was adopted there also, as the best for clocks intended to measure time very accurately. Lepaute, a very ingenious watchmaker in Paris, produced, about the year 1753, or some time before it, a 'scapement founded on that of Graham's dead-beat one. See Fig. 7. In Lepaute's, the rest of the teeth on the pallets was always with the same effect, because it was on the same circle, whichever of the pallets it rested upon; the impulse given was also always the same on whichever pallet it was given, the flanches of the pallets being planes equally inclined. This was no doubt some improvement on Graham's; but the teeth of the swing wheel in Lepaute's consisted of sixty small pins, thirty being arranged on each side of the rim of the wheel; and where pin-teeth are used, oil, which is in some degree necessary, cannot easily be kept to them, the attraction of the rim of the wheel constantly draining the oil from these pin sort of teeth; an evil which is perhaps not easily to be got the better of, unless by using stone pallets and hard tempered steel pins.

Notwithstanding the seeming superiority and great character which the dead beat 'scapement had long acquired over that of the *recoiling* one represented in Plate CCC. Fig. 8. this last had, however, its partizans; and among them were artists and amateurs possessed of first rate talents. Such were Harrison, Professor Ludlam of Cambridge, Berthoud, Smeaton, and others. Harrison, indeed, always rejected the dead beat 'scapement with a sort of indignation. The author of the Elements of Clock and Watch Making, has said a great deal in favour of the dead beat, and as much against that of the recoiling one, without having shown in what the difference consisted, or what was the cause of the good properties in the one, or what the defects in the other. It appears doubtful if these causes were known to him; yet he was very deservedly allowed to be a man of considerable genius. When pallets are intended to give a small recoil, their form, if properly made, differs very little from those made for the dead beat, as may be seen by the dotted lines upon the dead beat pallets in Fig. 6.

We shall endeavour to point out the properties and defects naturally inherent in each: When the teeth of the swing wheel, in the recoiling 'scapement, drop or fall on either of the pallets, the pallets, from their form, make all the wheels have a retrograde motion, opposing at the same time the pendulum in its ascent, and the descent, from the same cause, being equally promoted. This recoil, or retrograde motion of the wheels, which is imposed on them by the reaction of the pendulum, is sometimes nearly a third, sometimes nearly a half or more of the step previously advanced by the movement. This is perhaps the greatest, or the only defect that can properly be imputed to the recoiling 'scapement, and is the cause of the greater wearing in the holes pivots, and pinions, than that which takes place in a clock or watch having the dead beat, or cylindrical 'scapement; but this defect may be partly removed by making the recoil small, or a little more than merely a dead beat. After a recoiling clock has been brought to time, any additional motive force that is put to it will not greatly increase the arc of vibration, yet the clock will be found to go considerably faster; and it is known that where the arc of vibration is increased, the clock ought to go slower, as would be the case, in some small degree, with the simple pendulum. The form of the recoiling pallets tends to accelerate and multiply the number of vibrations, according to the increase of motive force impressed upon them, and hence the clock will gain on the time to which it was before regulated. Professor Ludlam, who had four clocks in his house, three of them with the dead beat, and the other with a recoil, said, "that none of them kept time, fair or foul, like the last: This kind of 'scapement gauges the pendulum; the dead beat leaves it at liberty." Were it necessary, many good proofs could be adduced of the excellent performance of clocks which had the recoiling 'scapement.

Let us now make a similar comparative trial with the dead beat 'scapement. An additional motive force being put to it, we find that the arc of vibration is considerably increased, and the clock, in consequence of this, goes very slow. There are two causes which produce this; the one is, the greater pressure by the swing wheel teeth on the circular part of the pallets during the time of rest; the other is, the increase of the arc of vibration. It was observed in the case of recoil, that an additional motive force made the clock go fast; and the same cause is found to make the clock having the dead beat go slow. As the causes are the same, and yet produce effects diametrically opposite, does not this evidently point out what is necessary to be done? The pallets should be so formed, as to have very little of a recoil, and as little of the dead beat; and here any variation in the motive force, or in the arc of vibration, will produce no sensible deviation from its settled rate of time-keeping. We have been informed, that a clock was given by Mr Thomas Grignion to the Society for the encouragement of Arts, Manufactures, &c. "which had a dead beat 'scapement, so constructed, or drawn off, that any diminution or addition of motive force would not alter the time-keeping of the clock." All the 'scapements of this kind which have been hitherto made, were commonly drawn off nearly in the same way as Mr Grignion's, that is, the distance between the centre of the pallets, and the centre of the swing wheel, is equal to one diameter of the wheel; and the line joining the centre of the pallets, and the acting part of them, is a tangent to the wheel, taking in ten teeth, and 'scaping on the eleventh. This is nearly the same as represented in Plate II. of Mr Cuming's book. The only difference is, that Mr Grignion's circle of rest is the same on each pallet. But whether it possesses the properties which have been ascribed to it, shall be left to the determination of those who may chuse to try this experiment with it.

Clockmakers in general have an idea, that, in a 'scapement, the pallets ought to take in seven, nine, or eleven teeth, thinking that an even number would not answer. This opinion seems to have arisen from the old crown wheel having always an odd number of teeth, because an even number could not have been so fit for it.

There seem to be no rules (as some have imagined) necessarily prescribed by either the recoiling or the dead beat 'scapement, for any particular distance, which the centre of the pallets ought to have from that of the swing wheel. The nearer that the centres of the swing wheel and pallets are, the less will be the number of teeth taken in by the pallets, when a tangent for them is drawn to the wheel. It is very obvious, that when the arms of the pallets are long, the greater will be the influence of the motive force on the vibrations of the pendulum, and *vice versa*, when the pallets are short, the angle of the 'scapement will naturally be greater than may be required, but this can be easily lessened by making the flanches so as to give any angle required. When this angle is not quite half a degree on each side, a very small motive force will keep a pretty heavy pendulum in motion. We have known a very good clockmaker, who thought that the flanch of the pallets was an arbitrary or fixed point, which could be made only in one way, and it was some little while before he could be convinced of the contrary. The flanches may be made so long as to act something like detents, so as to stop the wheel altogether by the teeth, (see Fig. 5.) or they may be made so short as to allow the wheel teeth to pass them altogether, without giving any impulse at all to them. It is true, that there would be no 'scapement here; only it shows that the flanch of the pallets may be made to give any angle of 'scapement, from a few minutes to two or three degrees. Whatever the angle of the flanches may be taken at, all that is requsite is, to make the wheel 'scape so, that the tooth, when it drops on the pallet, shall fall just beyond the corner of the flanch, on the circular or recoiling part of the pallet.

Harrison's clock pallets (which are sometimes made to act by means of very delicate springs, and sometimes by their own gravity), have a very considerable recoil, which was a most ingenious contrivance, to do away the necessity of having oil put to them. The construction of them seems to be but little known; and they have very rarely been adopted in practice. Indeed, it is a 'scapement of such a nature, that very few would be competent to execute it properly. The circumstances which led to the invention of them, were mentioned by Mr Harrison himself to the late Professor Robison. Having been sent for to look at a turret clock which had stopt, he went to it, though it was at a considerable distance from his home, and found that the pallets were very much in want of oil, which he then applied to them. On his returning, and ruminating by the way on the indifferent sort of treatment which he thought he had met with, after having come so far, he set himself to work, to contrive such a 'scapement, as should not give to others that trouble to which he had been put in consequence of this turret clock. Hence the origin of his pallets. A drawing and description of them will be given in a future part of this article.

The justly celebrated Mr Mudge, in a small tract, published in June 1763, relative to the best means of improving marine time-keepers, suggested, as a great advantage, that of making the moving power bend up, at every vibration of the balance, a small spring, whose returning force should be exerted in maintaining the motion of the balance, (see Plate CCC. Fig. 9.) The first essay of this most ingenious contrivance was a small pocket watch, executed by himself, nearly about this period; and this is the same principle which, some years afterwards, he adopted and practised in those time-keepers which he made.

About two or three years or so after the publication of this tract, Mr Cuming contrived a clock 'scapement, nearly on the same principle as that of Mudge's, where the motion of the pendulum was maintained by the force of gravity of two small balls, which acted upon it during the time of the descent. In this 'scapement, the centre of motion of the pallets is independent of that of the pendulum and verge, although the same, and concentric with them; two detents were applied for locking the swing wheel teeth, one for each pallet; from each of the pallet arbors a wire projected in an horizontal position, and on the end of these wires the balls were fixed, which were alternately raised up, at every vibration of the pendulum, by means of the action of the swing wheel teeth on the pallets. In a periodical philosophical journal, it is insinuated that Mudge had borrowed the idea of the 'scapement, which he used in his time-keepers, from this of Cuming's. That Mudge's 'scapement was his own invention, is clearly evident from the hisorical facts which have been stated. And although there is an apparent similarity between Cuming's and it, yet we are not inclined to be of opinion, that Mr Cuming borrowed his from Mudge's. The 'scapement of the clock made by Cuming for his Majesty the king in the year 1763, is of the free or detached kind, a name which was not then known. The improvement which he himself made upon it two or three years after, was to keep up the motion of the pendulum by the gravity of two small balls, independent of the motive force through the wheels of the movement. In this 'scapement, he insists on the adjustment between the pendulum screws and crutch being made so as just to unlock the swing wheel and no more. This can then be only unlocked at the time, when the force of the pendulum in its ascent is nearly gone, and that the pendulum should not then meet with the arm of the ball, but to receive it, as it were, just before the descent of the pendulum has commenced. In that part of Mr Mudge's, each pallet and detent were formed in one, and the unlocking takes place a considerable while before the end of the vibration. Thus, the springs which maintain the motion of the balance are bent up, not only by means of the action of the swing or balance wheel teeth on the pallets at every vibration till the wheel teeth are locked, but are still a little more bent up when unlocking by the exertion or momentum of the balance, or pendulum itself, previous to the vibrations being nearly finished; and this is one of the greatest properties of this 'scapement, whether it is applied to the balance and spring, or to the pendulum. No 'scapement appears to be better calculated than this is, to keep the pendulum or balance constantly up to the same arc of vibration, notwithstanding its having what some have been pleased to call a *defect* in the recoiling one, that of opposing the balance or pendulum in its ascent, and promoting its descent. In the spring pallet 'scapement, as in the recoiling one, the pendulum is opposed in its ascent, and has its descent equally promoted; but there is still a difference between them, notwithstanding this similarity. In the spring pallet 'scapement, no retrograde motion is given to the wheels, pinions, and pivots, which produces that early wearing on them, and where the seconds' hand partakes also of this retrograde motion, as in the common recoiling 'scapement. These are circumstances which have no place in that of the other. In such 'scapements as those now mentioned of Mudge's or Cuming's, it has been said by some, that it matters not what sort of work the clock movement is, or however ill it may be executed; since the motion of the pendulum is kept up by a force, which, in some degree, is independent of the motive force produced through the wheels in the movement. This may be so far true, yet there is no 'scapement, where any irregularity in the pitchings, pinions, &c. of the movement will be more readily discovered than in this, during the going of the clock, which will be very perceptible to the ear at the time of raising up the balls, or that of bending up the springs. We would therefore by no means advise, that this sort of 'scapement should be put to a movement of indifferent execution: on the contrary, it seems to require one finished in the best possible manner. The motive force put to it requires to be greater than that which is usually put to clocks having the dead beat 'scapement. It may be asked, whether weights or springs are the best for these sorts of 'scapements, which is perhaps a question not easy to be resolved. We confess that springs appear to be preferable; they seem to have, as it were, an alertness or quickness of action, when compared to the apparent heavy dull motion of gravity in the balls. The pivots which are at the centre of motion of the pallets and balls would be regarded by many as objectionable, from the belief that oil is necessary to them. Oil does not seem to us in the least degree requisite, considering the very small angle of motion which they would have; and we have always thought, for the same reason, that oil was not necessary to the pivots of such detents as were sometimes used in the detached 'scapement.

We shall now proceed to give a description of a clock 'scapement, on the same principle as that of Mudge's in his marine time-keepers, which was put to a very capital regulator or astronomical clock, made some years ago by Mr Thomas Reid, for Lord Gray's observatory at Kinfauns Castle. It had a mercurial compensation pendulum, and its time of going without winding up was forty-five days. The great wheel, the second wheel, and the swing wheel pivots, were run on rollers, three being put to each pivot. Rollers were first applied by Sully to the balance pivot of his marine time-keeper, and have since been adopted by Berthoud, Mudge, and others. They have sometimes been used for clock pivots, but in such an injudicious manner, that, in place of relieving the friction of the pivots, they have at last jambed them to such a degree, that the pivot could not at all turn or revolve upon them.

In Plate CCCI. Fig. 1. SW is the 'scapement or swing wheel, whose teeth are cut not unlike those of the wheel for a dead beat, but not near so deep. P, P are the pallets, the upper ends of whose arms at *s*, *s* are made very thin, so as to form a sort of springs, which must be made very delicate; for, if they are any way stiff, the force of the swing wheel will not be able to bend them when raising up the pallets. In order that these springs may have a sufficiency of strength, and at the same time be as delicate as possible, they are cut open at the bending parts, as may be seen at Fig. 2. These springs come from a kneed sort of sole, formed from the same piece of steel, by which sole they are screwed on to cocks, which are attached to the back or pillar plate of the clock-frame. The pallet arms must be made very light and stiff, in order that their weight may have the least possible load or burden on the springs; *a*, *a* are the arms of the pallets, as represented in the front view, Fig. 1. and are fully as broad as is necessary. Their thickness may be made much less than this. An edge view of the pallet arms is seen in Fig. 2. The acting parts of the pallets at P, P, Fig. 1. should be made of such thickness as to allow room for inserting a piece of ruby, agate, or any fine or hard sort of stone, the thickness of the stone being a very little more than that of the 'scapement or swing wheel. Each of these stone pallets has a sort of nib or detent for the wheel teeth, which is left at the end of the pallet flanches, as may easily be seen at the left hand pallet, Fig. 1. These nibs are made for the locking of the swing wheel teeth, and their use will be more particularly explained afterwards. On the back of the pallets are screwed to each a kneed light brass piece, *c*, *c*, as seen at Fig. 1. On the lower ends of these kneed pieces, the screws *d*, *d* are put through, serving the double purpose of adjusting the 'scapement, and setting the pendulum on beat. The upper part of the pendulum-rod is composed of a sort of frame, whose steel plates A, A, A, A, Fig. 1. are represented as being contained within the dotted circular lines; the thickness of these ring-sort of plates is seen at A, A, A, A, Fig. 2. This frame has three pillars to keep the plates properly together; and though they are not represented in the drawing, yet any one may readily conceive where their places ought to be, and what should be their length and height. At *e*, *e*, Fig 1. is seen on each side the ends of a thin steel plate, or traverse bar, which goes from plate to plate, and is fixed in the frame. An oblique view of one of them is seen at *e*, *e*, Fig. 2. In the steel frame plates, there is a circular opening, as represented by the dotted inner circle, Fig. 1. This opening must be of such a diameter as to allow the swing wheel and the cock which supports it to come freely through; a part of the cock is seen at *f*, *f*, Fig. 2. the sole of which F is screwed to the back of the pillar plate of the clock; the other knee K turns up to receive the pivot of the arbor of the swing wheel, the pivot at the other end of this arbor being supposed to run in the fore plate, or in a cock attached to it, and it is the pivot which carries the seconds' hand. This description of the manner by which the swing-wheel is supported within the pendulum, it is to be hoped will be sufficiently understood, notwithstanding the want of a proper drawing of that part. The swing-wheel S W, and part of its pinion arbor *g*, are seen edgewise at Fig. 2.; also the arm *a* of one of the pallets P, and its screw *d* bearing on the steel bar *e*, *e*. At the point of contact between the end of the screw *d* and the bar *e*, a small piece of fine stone may be inserted into each bar. This will prevent any wearing or magnetic attraction which might otherwise take place, if the screw was left solely to act on the steel bar; for the smallest wearing here would in some degree alter the effects of the 'scapement. In Fig. 1. B represents a part of the bar of the pendulum rod, which is fixed into the lower part of the steel frame; an edge view of this bar is seen at B, Fig. 2. At the upper part of the steel frame is inserted a piece *c*, *c*, Fig. 1. and 2.; in this piece the pendulum spring is fixed, whose top-piece goes into a strong brass cock, which is firmly attached to the back of the clock-case, or to a large stone pier; the end of the projecting part of this cock is seen at DD, Fig. 1. and a side view of this part of it at DD, Fig. 2. The top piece of the pendulum spring has a long and strong steel pin through it, which lies in a notch made across on the upper side and projecting part of the pendulum cock. By this strong pin, the pendulum is suspended. In the side of the pendulum-spring top-piece, is made a large hole, so as to admit freely a strong screw, the head of which is seen at E, Fig. 2. This screw serves to pinch the top-piece and cock firmly together, after the pendulum has been made to take a true vertical position. This strong pin and screw are not represented in the drawing, but the description which has been given will, it is presumed, easily supply this want. In the pendulum spring *h*, *h*, Figs. 1. and 2. may be seen an opening in it, so as to have the appearance of a double spring, as seen at *h*, *h*, Fig. 2. This opening is made to allow the spring parts of the pallets *s*, *s* to be brought very near together, and this at the bending part of the pendulum spring, so that it and the bending part of the pallet springs should be as it were in one common centre. A part only of the cocks on which the spring pallets are screwed, is represented by *k*, *k*, Fig. 1.: *m*, *m* are the heads of the screws by which they are fixed to these cocks. It must be observed here, that the spring pallets are so placed, that they should act on the line of suspension and gravitation of the pendulum, which necessarily brings the swing wheel to the place where it is; no verge, crutch, or fork, are required; the influence of the oil on the verge pivots, and the friction by the crutch or fork on the pendulum rod, are done away by this arrangement. The motion of the pendulum is kept up *entirely* by the force of the spring part of the pallets, independent of any impediment in the wheel work, so long as it has force sufficient to raise up the pallets readily and easily: this force may be considered as permanent and invariable, and so should be the arc described by the pendulum. If the length of the pendulum and of the arc it describes are invariable, so should be the time which is kept by the clock. Having described the parts which compose this 'scapement, it will now be requisite to show their mode of action, which is extremely simple.

When the pendulum is set in motion, it will, by means of either one or other of the screws *d*, unlock the swing wheel; which, in the drawing, is represented as being locked by one of its teeth on the nib or detent part of the right hand pallet; and the moment when the wheel is unlocked, the tooth at the left hand pallet is ready to press forward and raise up the pallet; and, of course, it bends up the spring. Let the pendulum be now brought to the right hand side, the steel bar *e* will meet with the screw *d*, and carrying it or pushing it on, it will by this means unlock the swing wheel, and allow it to escape. At this instant, the wheel tooth meeting with the pallet on the left hand side, it will force its way on the flanch, and raise it up till it is stopped by the detent or pallet nib. Here the wheel is locked until the return of the pendulum to that side, when it will be again unlocked. From the time of the unlocking at the right hand pallet, till the same takes place at the left hand, the pendulum, during its excursion to the right, is opposed by the spring part of the pallets, and on its return it is assisted by the same part, until the pendulum comes in contact with the point of the screw *d* on the left hand part: Here it is again opposed in its excursion, as far as the arc it describes; and on its descent or return, it is assisted or impelled by that of the spring part of the pallet, in conjunction with the force of gravity. In this clock, all that the motive force through the wheels has to do, is to raise up the pallets, by bending up the springs; and these, along with gravity, maintain the motion of the pendulum.

When clocks of the common construction get foul in the oil, or dirty, the arc of vibration falls off, or is less than what it was when the clock was clean and free. In this 'scapement, however, when the clock gets foul, the force of the swing wheel teeth, on the detent part of the pallets, will be lessened, consequently the wheel will more easily be unlocked by the pendulum: hence we may expect a small increase in the arc of vibration; but whether this will affect the time-keeping, by making it slow, must be left to the experience of those who may think of making such trials. It appears to us, that if any lengthening of the arc of vibration takes place, it will be equally accelerated by the greater tension of the spring part of the pallets.

Another clock, having the same kind of 'scapement, has since been made by Mr Thomas Reid, where the adjustments for 'scapement and beat are transferred from the pallets to the pendulum itself. By this means, these adjustments are not only easier made, but are effected without that danger to which the pallets are exposed, when this is done by the screws which are in them. This 'scapement has also been very advantageously applied, even where a a verge and crutch were adopted.

The following is a scheme and description of another clock 'scapement, which the writer of this article contrived about twelve or fifteen years ago.

In Plate CCCI. Fig. 3. SW is the swing wheel, whose diameter may be so large, as to be sufficiently free of the arbor of the wheel that runs into its pinion, which in eight-day clocks is the third. The teeth of this swing wheel are cut thus deep, in order that the wheel may be as light as possible, and the strength of the teeth little more than what is necessary to resist the action or force of a common clock weight through the wheels. They are what may be called the locking teeth, as will be more readily seen from the use of them, afterwards to be explained. Those called the impulse teeth, consist of very small tempered steel pins, inserted on the surface of the rim of the wheel on one side only. They are nearly two-tenths of an inch in height; and the smaller they are, so much more room will be given to the thickness of the pallets. If they have strength to support about eighty or a hundred grains, they will be strong enough. There is no rule required for placing them relatively to the locking teeth, only they may as well be opposite these teeth as anywhere else. P, P are the pallets, whose centre of motion is the same with that of the verge at *a*. These pallets are formed so as to have the arms sufficiently strong, and at the same time as light as may be. That part where the arms meet at the angle at *a*, has a steel socket made out of the same piece as the arms, being forged together in this manner. This socket is made to fit well on the verge, on which it is only twisted fast; and is turned pretty small on the outside, in order to allow the arbors of the detents to be laid as close to the verge as may be, so that their centres of motion may coincide as nearly as possible. A perfect coincidence of the centres might be obtained by using a hollow cylinder for the verge, with the detent arbors running in the inside of it, but this would have occasioned more trouble. That part of the pallet frame, as it may be called, in which is set the stone for receiving the action or impulse of the small pin teeth, is formed into a rectangular shape, so as to allow room for a dovetail groove, into which the stone pallets are fixed, as may be seen at PP, Fig. 3. and at P, Fig. 4, which also gives a side view of the verge at *a*, and where the socket of the pallets is seen, as fixed on the verge. At *b*, Fig. 4, is seen the outer end of one of the stone pallets made flush with the steel. That part of the stone pallets upon which the pin teeth act may be seen in Fig. 3, where they are represented in their respective positions relative to the pin teeth. Their shape or form is exactly that which gives the dead beat. In Fig 3. are seen the detents *d*, *d*, whose centre of motion is at *c*, *c*. They are fixed on their arbors by a thin steel socket, made as forged with the detents, much in the same way as the pallets were, as may be seen at *c*, Fig. 5, which gives a side view of one of the detents and its arbor. The screws *e e*, *f f*, in the arms of the detents, have a place made to receive them, which is more readily seen in Fig. 5. than in Fig. 3. The screws *e e*, serve for the purpose of adjusting that part of the 'scapement connected with the pallets, pushing the detents out from locking the wheel, by means of the locking teeth. The ends of the screws *e*, *e* on the unlocking, are met by the ends of the stone pallets, one of which is represented at *b*, Fig. 4. The screws *f*, *f*, serve to adjust the locking of the wheel teeth on the detents. *g*, *g* are brass rectangular pieces or studs, which are fixed to the inside of the pillar frame plate, and may be near an inch in height. The ends of the screws *f*, *f*, rest on the side of these studs, and according as they are more or less screwed through at the ends of the detents, so much less or more hold will the detent pieces have of the teeth. These holding pieces of the detents are not represented in the drawing, as they would have made other parts of it rather obscure. They are made of stone, and are fitted in by means of a dovetail, cut in a piece left for that purpose, on the inside of the detent arms, as may easily be conceived from the drawing, where it is represented in part at *e*, Fig. 5; and is in the line across the arm with the screw *e*, which is close by the edge of the detent stone-piece, which projects a little beyond the end of the screw. Having described the parts of the 'scapement, we shall now explain their mode of action. On the left hand side, the pin-tooth is represented as having just escaped its pallet, as seen in Fig. 3; but, previous to its having got on to the flanch of this pallet, let us conceive that the back of the pallet, or end piece *b* of it, had come, in consequence of the motion of the pendulum, to that side, and opposing the screw *e*, which is in the detent arm, pushes or carries it on with it, and consequently unlocks the tooth of the wheel, which then endeavours to get forward; but the pin-tooth, at this instant of unlocking, meeting with the flanch of the pallet at the lower edge inside, and pushing forwards on the flanch, by this means impels the pendulum, and after having escaped the pallet, the next locking tooth is received by the detent on the right hand side, where the wheel is now again locked. In the mean time, while the pendulum is describing that part of its vibration towards the left hand free and detached, as the pallets are now at liberty to move freely and independently of the small pin-teeth, on the return of the pendulum to the right hand side, the detent, by means of the back of the pallet on that side, is pushed out from locking the wheel, and, at the instant of the unlocking, the wheel gets forward, and the pin-tooth is at the same instant ready to get on the flanch of its pallet, and give new impulse to the pendulum, as is obvious by what is represented in the drawing, Fig. 3 After the pin-tooth has escaped the pallet, the wheel is again locked on the opposite or left hand side; the pendulum moves on to the right freely and independently till the next locking on the left takes place, and so on. It may be observed, that the unlocking takes place when the pendulum is near the lowest point, or point of rest, and of course where its force is nearly a maximum. Without attaching any thing to the merits of this 'scapement, we may remark, that the clock was observed from time to time by a very good transit instrument, and, during a period of eighty-three days, it kept within the second, without any interim apparent deviation. This degree of time-keeping seemed to be as much a matter of accident as otherwise; and cannot reasonably be expected from this, or any clock whatever, as a fixed or settled rate.

This 'scapement being a detached or free 'scapement, can at pleasure be converted either into a recoiling or a dead beat one, without so much as once disturbing or stopping the pendulum a single vibration. To make a dead beat of it, put in a peg of wood, or a small wire to each, so as to raise the detents free of the pallets; and these being left so as to keep them in this position, the pin-teeth will now fall on the circular parts of the pallets, and so on to the flanch, and the 'scapement is then, to all intents and purposes, a dead beat one. To make a recoiling one of it, let there be fixed to each arbor of the detents a wire, to project horizontally from them about 3½ or 4 inches long; the outer ends of the wires must be tapped about half an inch in length; provide two small brass balls, half an ounce weight each, having a hole through them, and tapped so as to screw on the wires; the balls can be put more or less home, and be adjusted proportionably to the force of the clock on the pendulum. No recoil will be seen by the seconds' hand; yet these balls will alternately oppose and assist the motion of the pendulum, as much as any recoiling pallets can possibly do; and as their effects on the pendulum will be exactly the same, it may be considered as a good recoiling 'scapement. This sort of detached 'scapement, by becoming a dead beat, or a recoiling one, at any time when required, makes it convenient for making various experiments with the different 'scapements.

We shall now proceed to describe a clock 'scapement, whose pallets require no oil, invented by the late Mr John Harrison, who received the parliamentary reward of 20,000*l*. for a marine time-keeper.

In Plate CCCI. Fig. 6. S W is the swing wheel, whose teeth are shorter than usual. On the verge is a brass arm, of a sort of cross and flat pronged form, as may be seen at *e, e, e*, Fig. 6. and at *e, e*, Figs. 7. and 8. Upon this arm are screwed two brass-cocks, marked *d, d*, in Fig. 6. and *d* in Figs. 7 and 8; the upper pivots of the pallet arbors, as seen at *a*, Figs. 7. and 8. run in these cocks, and the lower pivots in the end of the prongs. On the lower end of the pallet arbors is a brass socket to each, having freedom to move easily on them, and also a proper end-shake between the prongs and the pallet arms. On the end of the sockets, next the pallet arms, is rivetted a thin piece of brass to each, the piece on the socket of the driving pallet being shaped as seen at *h, h*, Figs. 6. and 7. and having two holes in it: one of these holes has a range, limited by a pin fixed to the brass arm from the verge; the other hole, which is at the outer end, allows range to a pin, which is fixed to an arm on the pallet arbor, as may be seen at Figs. 6. and 7. The piece of brass on the socket of the leading pallet arbor is shaped as seen at *k, k*, Figs. 6. and 8. having a tail which comes to rest on the outer edge of the cock *d*, after being carried a little way by the motion of the pallet; at the outer end, at *k*, is a small brass screw, serving as a counterbalance to the opposite arm or pallet hook. In this pallet arm is an opening, through which the swing wheel comes, as may be seen at *l*, Fig. 8. the arm at the other end being filed thin down, leaving a sort of shoulder on it. AB, Fig. 6. is a stout piece of brass, rivetted or screwed to the verge collet; CC is the steel crutch, having another arm, which comes up on the inside of the piece of brass; the ball or paume of the crutch is kept to the verge collet by a sort of spring collet, which has two screws outside, and through to the verge collet, the crutch having liberty to turn on the verge. The piece of brass AB has two short knees turned up, having a hole tapped in each to receive the two screws *s, s*, Fig. 6. whose ends bear on the upper arm of the crutch, and serve to move the arm to one side or the other, so as to put the pendulum or clock on beat; *p, p*, is a piece of hard wood put on the lower end of the crutch, having an opening in it, to clip or take in with the middle rod of a gridiron pendulum.

The parts of this 'scapement being described, it now remains to explain their action. The tooth of the swing wheel, which has hold of the hook of the leading or right hand pallet, carries it on, until another tooth meets with the hook or notch at the end of the driving pallet arm. When this takes place, the wheel is made to recoil a little back; at this instant, the hook of the leading pallet gets free of the tooth, and is made to rise clear of the top of it, by means of the counterbalancing of the brass arm, and the screw *k* at the end of it. The tooth of the swing wheel, which has now got into the notch at the end of the driving pallet arm, carries it forward, until another tooth, meeting with the hook of the leading pallet, causes the wheel again to recoil. This allows the notch of the driving pallet to get free of the tooth; and the brass piece, which is on the pallet arbor, falls down, till it comes to rest on the pin in the brass cross piece, making the pallet notch get quite clear of the top of the tooth, and so on. There is a great deal of ingenuity displayed in the contrivance of this 'scapement, yet the nice and ticklish balancing of the pallets occasion some degree of uncertainty in their operations; and whether the great recoil which it has may not be against the time-keeping of the clock, remains, perhaps, yet to be proved. Was it this 'scapement which was in a clock of Mr Harrison's, at his house in Orange Street, of whose going Mr Short said, "That he could depend on it to *one second in a month*," and "that it had been going for fourteen years at this rate?"

The properties of a good 'scapement are, that the impelling force should be applied in the most uniform and direct way, and with the least friction and loss of motive force: that it require little oil, or none; and that the oscillations of the regulator, whether it is a pendulum or a balance, be made in as free and undisturbed a manner as possible. The nice execution required in a 'scapement, whether for a clock or a watch, formerly engrossed so much of the attention of workmen, that they, in some measure, lost sight of the properties of the pendulum, as well as that of the spiral or balance pendulum spring, and thought that the time-keeping of their machines depended more on the 'scapement than on any other thing, without considering, that this, from principle, lies wholly, or almost wholly, in the pendulum and in the spiral spring. Berthoud imputes a notion like this to Harrison, for attempting to make the 'scapement in his time-keeper so that the long and short vibrations should be made in equal times. Whereas he says, "he ought to have looked for this in the isochronous property of the spiral or balance spring. But this property (he adds) was unknown at that time to the English artists; and was a discovery of those in France, from whom the English artists afterwards obtained it." If this be the case, how did it happen that Mr Mudge, long before the period when Le Roy and Berthoud disputed about the property of this spiral spring, each claiming the merit of having first made the discovery, mentioned in his tract, published in 1763, "That the pendulum or balance spring, from physical principles, made the balance perform the long and the short vibrations to equal times?" He learned this from Dr Hooke's works, with which he was well acquainted; and this property of springs was known to Dr Hooke, and pointed out by him nearly a hundred years before Mudge published his pamphlet. It is but too true, that few or none of the English artists seem to have been acquainted with these properties till very lately, though Mr Mudge had pointed them out so long before, and though they were contained in the works of Dr Hooke. Lepaute's book was published at Paris in 1767, and does not contain the most distant hint of these properties of the balance spring; hence they were not known there at the time when Lepaute wrote, otherwise he would have mentioned them. It was soon after this, that the disputes commenced between Le Roy and Berthoud regarding this subject.

Watch finishers always made the pendulum spring for the watches of their own finishing, while at the same time, knowing nothing of its properties, the general practice was to taper them, so that the coils, when bending or unbending, should preserve an equal distance with one another; and this method has been used ever since the application of the spiral spring. Those who finished watches for Mudge and Dutton, were never employed to make the pendulum spring. This was always done at home by either Mudge or Dutton themselves, who, no doubt, endeavoured to make them as nearly isochronous as possible. This, among other causes, perhaps gave their watches the celebrity which they at that time had deservedly acquired.

The pallets of the 'scapement at the turret clock in Greenwich Hospital, are said to have been contrived by Mr Smeaton. The following narrative will show how he came to be concerned in it. It may be observed, that at that time he was one of the commissioners.

The turret clock, which is in the cupola of Greenwich Hospital, was undertaken by the late Mr John Holmes, and executed under his directions by Mr Thwaites. But before any thing was done, Mr Holmes consulted two gentlemen, who happened to be his most intimate friends; the one was the Rev Mr Ludlam of Cambridge, the other Mr John Smeaton, both of whom were very eminently qualified to give such advice as was wanted in this business, not only about the 'scapement, but how every part of the clock should be fitted up, so as to insure safety and utility in its performance. Several very long and masterly letters (of which Mr Reid has copies, though none of the originals were ever published) passed between them on that occasion, and evince much ingenuity. They agreed that the 'scapement should have a recoil. Mr Smeaton recommended, that the pallets, in place of having planes, as was common for their acting parts, should have curved surfaces, the leading pallet being concave, and the driving one convex; and when the pendulum was at or near to the extremity of the vibration, the 'scapement should then be nearly dead. This was, as he said, what "old father Hindley at York had ultimately come into!" Mr Ludlam advised, that the swing wheel teeth should be thick and deep, and of such a shape as to roll as it were on the pallets, and not to slide on them, which would prevent biting or wearing. The pallet arms were of brass, made so as to put it in the power of the clockmaker to take the pallets very easily out, when repairing was necessary. These methods had long before this been used by Harrison, and were adopted in a clock of his in Trinity College, Cambridge, as mentioned by Mr Ludlam. Broad rubbing surfaces were strongly advised by them. Mr Smeaton at this period took away gudgeons from a mill wheel, whose diameters were only 2½ inches, and put others in their place of 8 inches, with great success, as it afterwards proved. On the same principles which have just now been mentioned, was the 'scapement made for the clock, which Mr Thomas Reid put up in St Andrew's Church, Edinburgh; and although it has been going for about thirty years, there is not yet the smallest appearance of biting or wearing on the pallets.

'Scapements have been divided into classes, one of which has been called those of the remontoir kind. Now, the mechanism of a remontoir may be applied to any 'scapement, and even then it can hardly be said to form a part of it, more than the wheels of the movement, or the weight which moves them.

The motive force passing through the wheels, may at times be unequally impressed upon the 'scapement either of a clock or watch. This idea gave rise to the invention of what has been called *remontoirs;* that is, that the movement should at intervals be made to wind up either a small weight, or bend up a delicate spring, which alone should give its force to the 'scapement, by which means the pendulum or balance was supposed to be always impelled by an equal and uniform force. The earliest thing of this sort was used about the year 1600. Huygens applied it to some of his clocks, and gives a description of it in his *Horologium Oscillatorium;* and Harrison had one in the marine time-keeper, which gained him the great reward. We are of opinion, that they are of no great use either to a clock or a spring time-piece; for if the pendulum of the one is well fixed, and the momentum of the ball is not too little, any small inequalities of the motive force through the wheels will hardly be perceptible; and in the spring time-keeper, the isochronism of the pendulum or balance spring is sufficient to correct any inequalities whatever in its motive force. As their mechanism, however, is curious, and has been rarely described, it may not be uninteresting to our readers to have such an account of it as would enable them to make and adopt it should they think it proper.

The one which we propose to describe, is that which was contrived by Mr Reid for the clock of St Andrew's church. Suppose a small frame, separate and independent of the clock frame, to contain two wheels, one of which is the swing wheel, having within it the 'scapement work. The other wheel is crossed out, so as to be as light as may be, the rim being left just so broad as to admit fixing on it seven kneed pieces or teeth, each about a quarter of an inch thick and half an inch long, three of which are on one side of the rim, and four on the other side. Three on each side have the knees of different heights, corresponding each to each. The fourth is a little higher than either of the third highest. The wheel on which these are fixed, has a tooth prolonged beyond the rim, of the same thickness and length as the others, making eight teeth in all, having a small space left between each. These teeth become as it were so many wheels in different planes, and are at equal distances from one another, with the same extent of radius coming to the centre of the swing wheel arbor, being just so much larger than that of the swing wheel, as to allow the swing wheel teeth to clear the arbor of it. The edge or side of the teeth which rest on the swing wheel arbor is a plane, and rounded off on the opposite side, to the point or angle formed by this plane. The arbor of the swing wheel has eight notches cut into it a little beyond the centre. These correspond to the eight teeth of the other wheel, and are sufficiently wide and deep to allow the teeth to pass freely through them. Each notch stands at an angle of 45 degrees to the one which is next it, which difference is continued along the arbor through the whole, making 360 degrees for one revolution of the swing wheel. On each of the arbors of these wheels was fixed a pulley having a square bottom, in which were set about ten hard tempered steel pins a little tapered, something like the pullies at the old thirty hour clocks, whose bottom was round in place of square. The pendulum was fixed to the wall of the steeple, as well as the frame containing the 'scapement work, and the apparatus which has been described. The arbor of the eight toothed wheel had one of its pivots prolonged with a square on the end outside. The clock frame containing the movement was in the centre of the steeple, and the pinion in it, which suppose to be that of the swing wheel, had one of its pivots also prolonged and squared outside. These squared pivots were connected by a steel rod and Hooke's joints. The main weight of the clock being put on, must urge not only the wheels to turn, but that of the wheel having the kneed teeth; but some one or other of these teeth pressing on the arbor of the swing wheel cannot turn, consequently none of those in the large frame can turn, nor can the swing wheel turn here unless some other means are used. An endless chain was provided, and passed over the two pullies fixed on the wheel arbors, and through two common pullies, to one of which is hung the small weight which is to turn round the swing wheel, and to the other a counter weight. The weight which turns the swing wheel, has its force placed on that side so as to make the wheel act properly with the pallets; now, while the swing wheel is turning, (the pendulum being supposed in its motion,) one of the other wheel teeth is gently pressing on its arbor. Whenever this tooth meets with its own notch, it will, by means of the main weight, be made to pass quickly through it; *while passing*, the small weight is wound up a little by the main one; the succeeding tooth then meeting with the swing wheel arbor, rests on it for a quarter of a minute, till its notch comes about; it then passes in its turn, and so on. The swing wheel makes a revolution every two minutes, in which time the wheel with the eight teeth makes also one. The minute hand, by this mechanism, when passing one of the notches, makes a start every quarter of a minute; at every such passing, the small weight is wound up a little by the great or main one. After the clock had gone a considerable time with this, it was found that the kneed teeth got a little swelled on their parts of rest, by the force of the main weight which made them fall on the swing wheel arbor. To remedy this, an endless screw wheel was put on the arbor of the remontoir wheel, (or wheel with the kneed teeth,) working into an upright endless screw, on the upper end of whose arbor was fixed a pretty large fly, in order to lessen the velocity of the remontoir wheel, and make the kneed teeth fall gently on the swing wheel arbor. This helped the swelling greatly, but did not entirely prevent it, though it existed now in a less degree. The endless chain had also a tendency to wear fast; in consequence of this, and of no provision having been made for the swelling of the kneed teeth, by making the notches on the swing wheel arbor much wider than was required for them when newly finished and first applied, this part of the remontoir was taken away, and the rod, with Hooke's joint, was put on the square of a pivot of the swing wheel, prolonged on the outside of its frame. These matters being guarded against, it might be well for some artist in future to try such a remontoir. During the four years it was in use, the clock went uncommonly well, and was the admiration of a gentleman who lived opposite the church, and who was an amateur in horology. One of Mr Reid's men who took an interest in this clock, said it did not do so well after the remontoir was taken away. This, however, may have been more owing to a change in the position of the weights, than to any thing else, occasioned by a chime of eight large bells being put up in the steeple. For the weights, in place of having their natural fall, were carried a great way up in the steeple above the bells and clock, in order to fall down again; and here a complication of rollers and pullies became requisite.

Harrison's remontoir is a very delicate spring, which is bent or wound up eight times in a minute. Were it necessary, a more obvious description could be given of it than that which is given with his time-keeper. In Haley's, the remontoir spring is bent up 150 times in a minute. In the 'scapement of Mudge's marine time-keepers, what may be called the remontoir, was bent up 300 times in a minute; the 'scapement here became in some degree wholly the remontoir. A variety of 'scapements may be seen in *Thiout*, and in some of the modern periodical works; yet, for the purpose of common or ordinary sort of clocks, they are confined chiefly to those of the dead beat, and the recoil. Where accurate performance is expected, some may have recourse to 'scapements of a different description.

About the year 1752, Le Roy, Lepaute, and other clockmakers in Paris, were much engaged in making clocks having only one wheel; and some had not even a single wheel in the movement. They were, however, more expensive in making, and performed much worse, than those which were constructed in the ordinary way. Simplicity in the machinery seems to have been their chief object. It requires, however, experience to know what simplicity in machinery is; although apparently more simple, a clock having two wheels in it, will not be equal to that having three or four; yet it does not follow, that, by having more wheels, the clock will be proportionally better: it has already been mentioned, that there are bounds which cannot be overstepped with impunity. This subject cannot be better exemplified than by making a comparison of one of Hindley's clocks, having two wheels, and giving thirty vibrations in a minute, with a clock giving the same number of vibrations in the same time, and with three wheels. The first or great wheel, in one of Hindley's, had 180 teeth, the second or swing wheel 120, and the pinion 8. The number of these teeth, and of the pinion leaves, amounts to 308. In the other, the wheels were 48, 40, and 30, and two pinions of 8; the sum of these is 134; the difference is 174, being the number of teeth more in the one than in the other, and more than the sum of the teeth in the three wheeled clock.

We shall now proceed to give a short account of such watch 'scapements as have been thought worthy of notice, from the old crown wheel and verge to the modern free or detached 'scapement; but, in order that the reader may be able to follow our descriptions, we have given from Berthoud a view of an assemblage of wheels and pinions, to represent something like the movement of a watch or a small clock. They are contained in a frame made for the purpose of allowing them to be more readily seen. Plate CCCII. Fig. 1. DE is the pillar plate, or pillar frame plate; G F the fore frame plate. A is the balance; the arbor or axis on which it is fixed is the verge, whose two pallets, *p*, *p*, scape with the teeth of the crown wheel C. The pivots of the balance turn or run in the frame; those of the crown wheel C, and of its pinion *d*, run in the potence I, and in the counter potence H, both of which are screwed on the inside of the pillar plate, the arbor of the pinion *d* being at right angles to the axis of the balance. The contrate wheel K and its pinion C turn also in the frame; the teeth of the contrate wheel pitch into the balance (or crown) wheel pinion, and can turn or drive it; the third wheel L, and its pinion *b*, run in the frame; the teeth of the third wheel pitch into the contrate wheel pinion, and turn it. The centre or second wheel M and its pinion *a*, have a long arbor going beyond the outside of the dial RS. The second wheel M, pitches with the third wheel pinion *b*, which it likewise can turn. N is the first or great wheel, pitching with the second wheel pinion *a*. X is the ratchet, *m* the click, and *n* its spring. On the arbor of the great wheel the ratchet is fixed; and, on winding up the main spring, the ratchet and arbor turn freely in the hole at the centre of the great wheel, which keeps its place during the time of winding. OP is the main spring deprived of its barrel; the inner end of it hooks on to the lower part of the great wheel arbor, and the outer end is hooked to the rim of the barrel, but is here fixed to a temporary stud. The force of the main spring, after being wound up, sets all the wheels and pinions in motion, and would oblige the ratchet and arbor to turn round independent of the great wheel; by this the main spring would be instantly unbent, but is prevented from this, by the click *m* being forced by its spring *n* to fall into the teeth of the ratchet, applying its end to the face of the ratchet teeth; by this means the main spring must unbend itself very slowly, the motion of the wheels being checked by the 'scaping of the verge with the crown wheel teeth. Q is the cannon pinion, put spring tight on the arbor of the second wheel, whose socket or cannon goes outside or beyond the dial, where it is squared for the purpose of the minute hand being put on it. T is the minute wheel, *g* its pinion; the cannon pinion pitches into or leads the minute wheel; the hour wheel V having a hollow arbor or socket *t*, is put on the cannon pinion, and is led by the minute pinion which pitches into its teeth. It is on the socket of the hour wheel which comes a little above the dial, that the hour hand is put. When a wheel pitches with a pinion and turns it, the pinion is said to be driven by the wheel; if the pinion turns the wheel, the wheel is then said to be led by the pinion. The pendulum or balance spring *s s* has its inner end fixed to a collet, which goes spring tight on the arbor of the balance; the outer end is fixed or pinned to a stud fixed on the inside of the fore plate. In the action of the crown wheel teeth on the pallets, the balance spring is either bent up or unbending; it is by the small force of it, that the balance is made to give twice the number of vibrations that it would give without it. It should have been observed, that, by putting a key on the square of the cannon pinion, and turning it about, this will not only move the minute hand about, but will oblige the hour hand to follow slowly, in the ratio of one turn to twelve of the minute hand.

The first watches may readily be supposed to have been of rude execution. Having no pendulum spring, and only an hour hand, and being wound up twice a day, they could not be expected to keep time nearer than 15 or 20 minutes in the twelve hours. After the application of the pendulum spring, they would no doubt go considerably better, and may now be made to keep time sufficiently correct for the ordinary purposes of life. Indeed, when the crown wheel and verge 'scapement is executed with care, it will do uncommonly well. Let the angle of the verge be 93 or 95 degrees, the teeth of the crown wheel undercut to an angle of 28 or 30 degrees, and scaped as near to the body of the verge as just to be clear of it, (it is to be understood here that the verge holes are jewelled.) To carry the matter still farther, the body may so far be taken away as to admit the teeth near to the centre, which will tend to allow the vibrations of the balance to move more freely and independently; but this requires such nice execution *here*, and in other parts of the 'scapement, that from not having encouragement, few are fit to execute it, and therefore it may in general be safer not to bring the wheel teeth so near to the verge. Care must also be taken to have the balance of a proper diameter and weight, which has of late been much neglected since the old fashion of half timing has been left off, that is, making the watch go without the pendulum spring, if it goes slow 30, 32, or 33 minutes in the hour, the balance may be considered of such a weight as to be in no danger of knocking on the banking from any external motion the watch may meet with in fair wearing. When the pallets of the verge are banked on pins in the potence, they should, to prevent straining, both bank at the same time, alternately the face of one pallet on a pin, when the back of the other is on its pin; or the banking may be done by a pin in the rim of the balance, but not near the edge of it. Which of the two is preferable, we shall not stop to determine.

The verge watch, as has been already said, when properly executed, will perform extremely well. About thirty years ago or more, the writer of this article had some of them made up in such a way, that they went fully as well as any horizontal 'scapement, and for a longer time; this last requiring oil to the cylinder, after going ten or twelve months. Oil, however, should never be allowed to come near the wheel teeth or pallets of a verge. Verge or contrate wheel watches have, of late years, been very much overlooked and neglected in many respects, and in none more so than in the relative position of the balance wheel, and contrate wheel arbors. They are rarely seen but at a considerable distance from one another, which gives a very oblique direction in the pitching of the contrate wheel with the balance wheel pinion. It is well known, that where force is indirectly or obliquely applied, it will work under great disadvantage. These arbors ought to be placed as near to each other as can be. In order to obtain this, reduce the balance wheel pinion arbor *towards the end to the smallest size it will bear*, and turning a hollow out of that of the contrate wheel, will allow them to come very near the line of their centres. To get this pitching to the greatest advantage, some place the counter potence within the arbor of the contrate wheel, so as to have the line of the balance wheel pinion direct to the centre of the *contrate wheel*, as may be seen in Plate CCCII. Fig. 1.

It has been recommended by a very celebrated artist, that the movement wheels should be placed in such a manner as to act at equal distances from the pivots of those pinions which they drive, in order to divide the pressure or action of the wheel between the pivots, and that one should not bear more than the other. This is apparently sound reasoning; but having put it in execution, the pivots unexpectedly seemed to wear very fast, even more so than in the common barred movement; the pivots, it is true, were small, and the motive force rather great. It is to be wished that it were again tried by others to bring it to the test. No pivots have been found to stand so well as those in movements of the double barred sort.

A pendulum spring collet, made as it ought to be, is as seldom to be met with, as that which we have noticed regarding the *position* of the contrate and balance wheel arbors. Yet simple as the thing is, it seems to require a rule to shew *how it should be done*, there appearing to be none, if we may judge by the greatest part of those which have hitherto been made. The ring of the collet should be no broader than to allow a hole to receive the pendulum spring, and the pin which fixes it. The *slit* in the collet, for the purpose of its being always spring tight on the inside taper of a cylinder or verge collet, should be put close to where the small end of the pin comes, when the spring is pinned in. The pendulum spring, in this case, will have the first or inner coil at such a distance, as to allow the point of a small screw-driver to get into the slit without any danger to the spring, when it is wanted to set the collet and spring to any required place. If the slit is put at the other end of the pin, where it is oftener than anywhere else, it is evident that the workman cannot get into it without danger. The outer end of the pendulum spring ought to be pinned or fixed into a brass stud or cock, in performing which operation it goes easily on; whereas with steel cocks or studs, there is a kind of crossness and trouble, which shews that they should never be used.

Studs are, in general, very improperly placed, being at a greater distance from the curb pins than is requisite. We have seen this distance so great, that the motion of the pendulum spring between the stud and the pins was such, as to take away a part from every vibration of the balance; which is something like a pendulum when suspended to a vibratory cock, where it would not be allowed to have half the motion it would otherwise have acquired.

A few years ago, our modern improvers would have the joint transferred from the pillar plate to the brass edge, than which nothing worse could have been proposed. In the old way, the whole of the movement was kept in its place by the united assistance of the joint, and of the bolt and its spring; whereas, in the other way, the movement had its sole dependence on the pins of the brass edge feet, from which it would be disengaged by violent exercise on horseback, &c.

From what has been said of the imperfections in watches, it may be seen, that they are inevitable, arising from a want of energy of mind in workmen, of which not one in a hundred is possessed. Can it be supposed, that every new watch, which is purchased, is complete, and requires no assistance? Whoever thinks so, must be disappointed. Persons of this description, on finding it not to go as they expected, bring it to a watchmaker, many of whom cannot put it in a better state than that in which the workman left it. But it is not brought to him with the view of any thing being done to it, but to see what is the matter with it; never considering, that any irregular going or stopping must imply some fault or other, and is the very cause that brings them to the watchmaker. It does not follow, however, from this, that every watch which stops is badly executed; this will happen sometimes with those of the very best execution, and frequently from an over-nicety of execution. On its being left with him, he takes it down, to examine what is wanting to make it keep time. The owner, on being told afterwards that it will cost so much to make it do what is required, strongly suspects, though he is polite enough not to say it, that there must be some imposition on the part of the watchmaker. Much is the trouble which many have of rectifying the faults of work given in to them, and thought to be complete, and much money is paid to others to have them rectified. We have known four guineas paid to a workman for doing a particular branch; and not being executed to the satisfaction of the watchmaker, he has given half as much more to another to have it corrected. There are as few excel in this art as in those of sculpture, painting, and engraving, which are called the fine arts, a name to which the other is equally entitled, but which labours under the great misfortune that few or none are able to appreciate its merits.

The old 'scapement, even after the application of the pendulumspring, not giving that satisfaction which was required, induced Huygens and Hooke to think of other means of improving it, or to substitute a superior mechanism in its place. In this pursuit, the mechanical talents of Hooke stood conspicuously eminent over those of the justly celebrated Huygens.

Some of the movements of Huygens' watches, or timekeepers, were much larger than those of our box chronometers. The contrate wheel was cut into teeth of the same form as those of the common crown wheel, and made to 'scape with a verge of the usual kind. On the axis of this verge was a sort of contrate or crown wheel, having teeth like the ordinary contrate wheel, which drove a pinion fixed on the axis of the balance. The verge, when 'scaping with its wheel, caused the balance to make several revolutions from every impulse on the pallets. Plate CCCII. Fig. 2. Some of them had no pendulum spring, having been made perhaps before its application. When the balance made several revolutions in every vibration, each being two seconds, this 'scapement would be but ill suited for the coils of a pendulum-spring. Those having the pendulumspring appeared about 1675. This was the origin of half-timing, upon seeing, when the pendulumspring was applied, that it made the balance give two vibrations in the same time that it gave one without it. About the same period, Dr Hooke brought into notice his watch with a new 'scapement; which, for seventeen years before, he had been privately endeavouring to improve. This was very different from the old crown wheel one, and as much so from that of Huygens. It had two balances, on the axis of each of which was a toothed wheel, pitching into one another. The verge or axis of these balances had each a pallet on it. The balancewheel was flat, having a few ratchet or saw-like teeth; its arbor run in the frame, parallel to those of the balances, at a point equally distant from them; the three points forming, as it were, the angles of an equilateral triangle. When a tooth of the balancewheel gave impulse on one pallet, the other, by the pitching of the two wheels, was brought about to meet another tooth, (after the wheel had escaped from the pallet on the opposite side,) in order to receive impulse in its turn. There was a pendulumspring on one of the balances, and the object of their being pitched together was to prevent the effects of external motion on them, while it served the double purpose of bringing alternately about the pallets, which still gave some recoil to the wheels by the reaction of the balances. Although this was a very ingenious contrivance for a 'scapement, yet it appears not to have given that satisfaction which was expected from it, (probably from indifferent execution, which, from Sully's account, was the case,) and the old one was again adopted. However, some years afterwards, other artists, among whom was Dutertre, were attracted by this 'scapement of Dr Hooke's, and were led, from time to time, to make improvements on it. From it originated the duplex 'scapement, which has of late years been so much in repute. A large old German clock had a 'scapement on the same principle as the above, of which the maker's name is unknown. Dr Hooke's claim to his own 'scapement, remains however undisputed.

The famous Tompion, who contributed greatly to bring the art of Horology in England to that reputation which it had acquired for a long period of sixty years or more, during which he practised it, made a 'scapement about 1695, and flattered himself with being very successful. The verge or axis of the balance was a small solid steel cylinder, cut across at the middle, and nearly half way down; along the length way of this part cut across, a deep angular notch was made, forming a sort of pallet on the right hand side; the balance wheel was flat, and much like Dr Hooke's; and the spaces between the teeth sufficiently wide to allow the cylinder to turn freely between them. When a tooth of the wheel impelled the pallet, and when on escaping from it, the tooth following dropped on the outside of the cylinder, near the left edge, resting on the cylinder during this vibration of the balance, after passing the left edge, and meeting a little recoil, it got on the pallet, and gave a new impulse, which was given only at every second vibration. An excellent property was observed in this 'scapement, that any inequalities in the motive force made no deviation in its timekeeping; but the friction of the balance wheel teeth on the cylinder and its edges was so great and destructive, that it was given up in consequence of it.

Knowing what Tompion had been doing, being bred under him, Graham, a good many years after, set to work with the cylinder 'scapement, and ultimately succeeded. Although this 'scapement is now pretty generally known, yet we may be allowed to give an account of what he did. Plate CCCII. Fig. 3. In place of Tompion's solid cylinder he made a hollow one; on the points of the wheel teeth of Tompion were raised something like small pins or stems, on the tops of which a sort of inclined or curved wedge-like teeth were formed, of such a length as to have very little freedom when in the inside of the cylinder, and the outside of the cylinder to have the same freedom between the point of one tooth and the heel of the other. A notch or opening was made across the cylinder, not quite half way down the diameter; the edges of the cylinder made by this opening were dressed so that the curved edge of the tooth might operate easily on them; the right hand edge was flanched outward, the left one rounded; when the balance was at rest, and the wheel in its place to 'scape, the point of the tooth got then just in on the cylinder edges, and no more; a second notch was made below the other, to allow the bottom of the wheel to pass, leaving hardly a fourth of the circumference of the cylinder, the other leaving more than a semicircle. The highest part of the wedge or curved tooth being on a circle, greater or beyond that on which the point was, it is evident that, if the wheel is urged forward, it will make the cylinder to turn, and the angle of 'scapement will be according to the height of the wedge. When a tooth of the cylinder wheel escapes from the left edge of the cylinder, the point of it falls into the inside of the cylinder, after reposing there, and then passing and impelling the right hand edge; on escaping it, the point of the succeeding tooth drops on the outside of the cylinder, where it reposes; on the return of the balance, it gets on the left hand edge, giving a new impulse, and so on. The teeth impel at both edges of the cylinder, giving by each a vibration to the balance.

This 'scapement being the best of any that had preceded it, (Debaufre's perhaps excepted) procured for Graham's watches a very considerable reputation, as their performance was much superior to that of those of the old construction. However, on comparing the going of some of Graham's with those of a later date, we confess that none of his, though excellent, were ever equal to them in this. The cylinders were rather large in diameter, the balance too light, the motive force too weak, and he had great difficulty in obtaining good pendulum spring wire, meeting sometimes with iron, where he expected steel wire. Watches having the cylinder 'scapement were not known in France till 1728, when Julien Le Roy commissioned one of them from Graham. They were losing their character here, some time before the introduction of the duplex, which contributed afterwards still more to bring them down. The duplex will in its turn be supplanted, for reasons which will be afterwards noticed. Flat movements, shallow balance wheels, steel and brass of bad materials, from the difficulty of getting them good, injudicious execution, and low prices, must have tended to make the cylinder 'scapements so bad as they were of late; many of the cylinders were destroyed and cut to pieces in a very few years, and some of them could not last so long. Let these be compared with the cylinder 'scapements of old Hull, many of which that we have seen, have little or no impression even on their edges, after having been in use thirty years and upwards. Of what did Hull's art consist? There must have been some causes for it; but what these are, we shall not attempt to conjecture. As Graham, with whom he was instructed, did, Hull soldered in the plugs of his cylinders, with silver solder, which caused a very tedious process afterwards in making the cylinder; but this is not offered as any reason for his excelling in the art of cylinder 'scapement making. The acting edges of the teeth have hitherto been made too thin, particularly for steel cylinders, with the view of lessening the friction; but, from cutting soon, this friction increased, and was worse than a greater friction which was constant.

When the vibrations of the balance are at the lowest point, the resistance of the pendulum spring is at the least; but the more it is bent or unbent, the greater is the resistance; consequently, when at the height of the wedge or tooth, it is greater than when the tooth first begins to act. Two or three different curves for this purpose have been imagined; one approaching nearly to a right line, which is supposed to give the wheel time to acquire a velocity during the passing of two-thirds of the curve, and the least resistance of the spring, by which the other third more readily overcomes, when the resistance to it is at the greatest. This has been thought to give a greater extent to the arc of vibration, and has been adopted by the French artists. Another curve, where equal spaces make the balance describe equal portions of a circle, is thought to give the least wearing to the edges of the cylinder, and is that which is practised by our 'scapement makers. Arguments equally good for either, it appears, might be given.

The weight and diameter of the balance, are circumstances very materially connected with the wearing on the cylinder edges. Whatever will prevent this wearing, should be carefully attended to. When the diameter is large, the balance must of consequence be less heavy; a sort of sluggishness in its motion takes place, the pendulum spring making great resistance to the teeth passing the cylinder edges, and causing wearing to go rapidly on. On the contrary, when the diameter is small, and the weight at a proper medium, there is an alertness in the vibration; the momentum of the balance has such force over the pendulum spring, that it allows the teeth to pass the edges quickly; and hence there is a less tendency to wear them. The diameter of the balance should be less than that in a verge watch of equal size, nor should it be heavier than just not to allow setting, unless where a going in time of winding is used. The cylinder 'scapement, on the whole, must be allowed to be a very excellent one; and where care is taken to have it made as it ought to be, such watches will give very good performance. Provision for oil on the cylinder should be made as ample as can be admitted; that is, the part where the tooth acts, should be as distant from the notch where the wheel bottom passes as possible, and at the same time more distant from the upper copper plug; the lower notch should not be longer than to give freedom to the wheel bottom to pass easily. When they are made long, which they frequently are, the cylinder will break there, if the watch receive a slight shock from falling. The acting part of the tooth, as has already been noticed, should not be too thin, nor the stems too short. If the diameter of the balance is too great, any addition of motive force will make the watch go slow; if too little, the watch will go fast; and if of a proper weight and diameter, any addition of motive force will make no change on the time-keeping. We have made the motive force more than double, and no change took place; the pendulum spring no doubt had its share in keeping up this uniformity. Balances whose diameters are rather small, will have a natural tendency to cross farther, that is, the arcs of vibration will be greater than where the diameters are great. Their weight will be in the ratio of the squares of their diameters; from which it follows, that if the balance is taken away from a watch which has been regulated, and another put in its place, having the diameter only one half of the former, before the watch could be regulated with the same pendulum spring, the balance would require to be four times heavier than the first. One way of estimating the force of a body in motion, is to multiply the mass by the velocity. Let us then calculate the respective forces of two balances, whose diameters are to one another as two to four. The radii in this case express the velocity. According to this principle, we shall have for the small balance two for the radius, multiplied by eight of the mass, equal to sixteen; and for the great one, four of the radius by two of the mass, equal to eight; sixteen and eight are then the products of the mass by the velocities; consequently they express the force from the centre of percussion of each balance; and as it is double in the small one, it is evident that the arcs of vibration will be greater, having the faculty of overcoming easily any resistance opposed to it by the pendulum spring, without requiring any additional motive force.

Let us take an example done in another way, which is the square of the product of the diameter multiplied by the velocity or number of degrees in the vibration, and this again multiplied by the mass or weight, so as to compare the relative momentum of two balances of different diameters, &c. Suppose one balance to be .8 of an inch in diameter, the degrees of vibration 240, and the weight eight grains; the other .7 of an inch in diameter, the arc of vibration 280°, and the weight 10 grains

$$240 \times .8 = 192 \times 192 = 36764 \times 8 = 294112.$$
$$280 \times .7 = 196 \times 196 = 38416 \times 10 = 384160.$$

The balance having the smaller diameter, has its momentum to that of the greater, as 384 is to 294. When the arcs of vibration are great, the nearer to isochronism will the long and short ones be.

When a little expence in the cylinder or horizontal 'scapement is not grudged, a ruby cylinder is certainly a great acquisition to prevent wearing on the edges; if it is not steel cased, and wholly of stone, it is so much the better, giving a little more scope to extend the limits of the banking, the steel crank of the other confining the extent of banking. There is no doubt a greater risk of breaking than in the cased one; yet this might be considerably lessened, were some attention paid to make the notch which frees the bottom of the wheel, as has been proposed in the case of the steel cylinder, no longer than is necessary. It would be desirable to have the cylinder, formed by the strata of the sapphire or ruby, being placed in a vertical position instead of a horizontal one. This is surely attainable, when we know that diamond splitters can distinguish the strata or layers of the diamond, a stone which may be supposed more compact than either the ruby or sapphire. We have seen a cylinder, wholly of stone, in a watch belonging to a gentleman, who was wearing it when between 70 and 80 years of age; he used frequently to let it fall without any accident happening to the cylinder. Three small griffs or cocks placed on the potence plate, so as to allow the balance edge to come into notches fitted for it, and having sufficient freedom, would prevent either the cylinder or the cock pivot from breaking. A little practice should make the stone cylinder easier, and perhaps cheaper made, than the cased one; at all events, even on equal terms, it ought to be the preferable of the two. From what has already been said, it appears that the weight and diameter of the balance are matters not merely arbitrary; for if the motive force is too great for that of the force of the balance, the watch will go fast when in the laying or horizontal position, and slow when in the vertical or hanging position: by diminishing either the motive force, or making the balance heavier, the watch may be made to go the same in both positions. The properties of the pendulum spring may conduce a little to this. It is in some degree a desideratum for a pocket watch to have the balance pivots and holes made so that the balance with its spring, when in a state by itself, and free of any communication with the wheels, should vibrate the same length of time, whether it is in a vertical or a horizontal position. We know when it is in the last, that it will continue to vibrate twice the length of time that it will do in the other. We are humbly of opinion that this could be come at. But who will be at the trouble and expence to make such experiments as may lead to it? Mr Earnshaw's pivots, with flat ends and shallow holes, should come very near to this object. About forty years ago we used to hollow out the ends of balance pivots.

In the interim, between Tompion's having left off his trials in attempting the horizontal 'scapement, and Graham's having brought it to a state of perfection, M. Facio, a native of Geneva, having discovered the art of piercing holes in rubies, or any hard precious stone, came to Paris with this art as a secret; and not being well received either by the Duke of Orleans, at that time regent of France, or by the watchmakers, he repaired to London with it about the year 1700, which was at that time a school where the art of horology was more cultivated than at Paris. He was admitted a member of the Royal Society, and having entered into a kind of partnership with a native of France, who had been settled in London, whose name was Debaufre, they carried on the business of watch-jewelling.* Facio's partner had, at this time, contrived a new 'scapement; it was a dead beat one, which was the thing now sought for. Plate CCCII. Fig. 4. The balance and balance wheel holes of it were jewelled; the pallet was made of diamond, formed from a very short cylinder of two-tenths of an inch in diameter; the upper end of the cylinder was cut down nearly one-half of the diameter, and flanched to the lower end and opposite side, rounded off from the circular part of the base left at top, to the lower end of the flanch, resembling something like a cone bent over, and wanting a part of the top. Two flat balance wheels, having ratchet or crown wheel sort of teeth, were on the same arbor, the teeth of the one being opposite to the middle of the spaces of the other; the distance between these wheels was a little less than the diameter of the cylinder; the drop of the teeth in 'scaping, falls on what was left of the upper base of the cylinder, (the lower base being taken away in forming the pallet) and near to the edge formed from the flanch; here they rested during the time of the vibration of the balance. On the return, the tooth gets on the flanch, and passes over it, during which, giving impulse to the balance, and escaping at the lower end, a tooth of the other wheel drops opposite on the same base of the cylinder, and so on. A watch having this 'scapement, and bearing Debaufre's name, was put for trial into the hands of Sir Isaac Newton, who, in shewing it to Sully in 1704, gave a very flattering account of its performance. It attracted Sully's notice very much, but thinking it by no means well executed, and not being quite satisfied with two wheels, it was thought that an improvement would be made by having one wheel only and two pallets, which was part of the scheme of the 'scapement he adopted for his marine time-keeper made in 1721. Considering the genius which Sully was allowed to possess, this was by no means an improvement on Debaufre's 'scapement.

Although an Englishman, Sully's name was unknown to his countrymen; and would have remained so, had it not been for the accounts given of him by the French artists, in whom he excited an emulation, and whom he inspired with a taste to acquire such a pre-eminence in their profession as had been before unknown to them. Julien le Roy, who was intimately acquainted with Sully, and Berthoud, are uncommonly lavish of their encomiums on him. Soon after he had completed his apprenticeship with Mr Gretton, watchmaker in London, he went over into Holland, Germany, and Austria, and attracting the notice of several of the princes and nobility, he was much employed by them. Having seen, in the library of Prince Eugene, the *Memoirs of the Royal Academy of Sciences of Paris*, he eagerly acquired the French language in order to read them. This excited in him a strong desire to see Paris, to which he repaired about the year 1713 or 1714, under the patronage, and in the suite of the Duke of Aremburg, at whose hotel he lodged, with a pension of 600 livres. He had not been long there, when our countryman, Law of Lauriston, under the authority of the court of Versailles, got him engaged to establish a manufactory of clocks and watches. In consequence of this he came twice to London, and having carried away a great number of workmen at a vast expence, and spent much money on tools and other articles, Law began to murmur, and the establishment in two years or little more fell to the ground. This made him complain bitterly of his bad fortune to a friend; but fortunately a nobleman to whom this was mentioned, feeling much for the disagreeable situation in which Sully was placed, sent him in a present some shares in the public funds, value 12,000 livres, which enabled him, for several years afterwards, to pursue very zealously his favourite scheme of making a marine time-keeper to ascertain the longitude at sea. In this attempt he was not so successful

* Some of Debaufre's family, or name, were at this profession in London so late as 1773.

in his first trials, as he had led himself to expect. It was in general believed, however, that had he lived he would have been the first to have deservedly acquired one or other of the premiums which were before that time offered, by four of the greatest maritime powers in Europe, to those who should produce a time-keeper which could ascertain, to a certain extent, the longitude at sea. Philip the Third, who ascended the throne of Spain in 1598, was the first who proposed a reward of 1000 crowns for this invention. The States of Holland soon after followed his example, and offered 100,000 florins. The British Parliament, in the reign of Queen Anne, voted 20,000*l.* sterling for the same purpose; and the Duke of Orleans, Regent of France, in 1716, promised, in the name of the King, 100,000 livres. Sully may literally be said to have died a martyr to the cause in which he was engaged. Having got a false address to a person who it was said was occupied in the same pursuit with himself, he got so overheated in his anxious and vain endeavours to find him out, that he died in a few days after at Paris, in the month of October 1728, and was buried with great pomp in the church of St Sulpicius. Sully acted so conspicuous a part in the profession, that no apology is necessary for giving this short account of him.

It may be observed here, that Debaufre's 'scapement has this advantage, which is not in Graham's, that the impulse is given the same in every vibration; and the time of rest on both sides is the same, bearing mostly on the foot pivot end, and a little on the sides of the pivots, and not wholly on the sides of the pivots, as in Graham's. Having made one or two watches, to which this 'scapement was put, they were found to perform very well; and we would recommend it to the attention of 'scapement makers: A little practice will make the execution of it very easy. The two thin steel wheels may at pleasure be placed at any distance from one another; their diameters should be as large as can be admitted between the potence foot and the verge collet. An agate, or any hard stone, for the pallet, whose height is half the spaces between the teeth, or a little less, is fixed on the verge or axis of the balance; the level of the base of the pallet on which the teeth rest being a very little above that of the line of the centre of the balance wheel pinion. The teeth must be a very little undercut, so that the points only may rest on the pallet. The verge should be placed more inward in the frame than in the common contrate wheel movement, in order to give room for the balance wheels. The necessity of a contrate wheel movement for this 'scapement is a trifling objection, which will wear away in spite of prejudice.

In 1722, the Abbé Hautefeuille, who long before this had at Paris disputed, in a process of law with Huygens, the right of the invention and application of the pendulum spring to the balance of a watch, published a quarto pamphlet, containing a description of three new constructions of 'scapements for watches. One of these was the anchor, or recoiling 'scapement, on the verge of which was attached a small toothed segment of a circle, or rack, working into a pinion, which was the axis of the balance. Plate CCCII. Fig. 5. The idea of the axis of the balance being a pinion, seems to have been taken from the 'scapement of Huygens, with this difference only, that the balance should not make so many revolutions as that of Huygens, and is contrived so as to make scarcely one revolution at every vibration. This 'scapement is the same as it came from the hands of Hautefeuille, without any improvement having been made upon it even to this day, although a patent was taken out for the same invention above twenty years ago, by some person in Liverpool. The name of lever watches, which they received from the patentees, is that which is generally given to those having this 'scapement, which is the same that Berthoud has described in his *Essai sur l'Horlogerie*, published in 1763; see tom. ii. No. 1933, and plate xxiii. fig. 5, of which our Figure is a copy. Berthoud, under certain modifications, introduced the principle of this 'scapement into some of his marine time-keepers.

A very able and ingenious artist at Paris, M. Dutertre, who was zealous in his profession, and had considerable success in his pursuits, invented, in 1724, a new 'scapement, or rather improved that of Dr Hooke's with two balances, which has already been described. Plate CCCII. Fig. 6. The additions and improvements, however, which he made, were so great, as to give him a sort of title to claim it as his own, and to render it, in the opinion of good judges, the best 'scapement by far that was known at that time. The additions which he made, consisted in putting another wheel upon the same arbor with the first, but it was considerably larger in diameter, having the same number of teeth with the other, and forming the principal merit of the 'scapement. The balance arbors at one place were made rather thicker than usual, for the purpose of having notches cut across them, and as deep as to the centre. This part of the arbors becomes then a semicylinder. The larger wheel, which may be called that of *arrête*, or repose, is placed on its arbor, so as to correspond with the semicylinders and their notches, the points of whose teeth are made just to clear the bottom of the notches, alternately passing one of them, and resting on the semicylindrical part of the other. The action of the two wheels shall now be explained. Let us suppose, that one of the larger wheel teeth, after reposing on one of the semicylinders, is, on the return of the vibration of the balance, admitted to pass through the notch; after having passed, a tooth of the impulse-wheel falls on the corresponding pallet, gives impulse, carrying it on till it escapes; when another tooth of the wheel of repose falls on the other semicylinder, and rests there until the return of the vibration of the other balance; when it passes the notch in its turn, and the corresponding pallet presenting itself, is impelled by a tooth of the impulse wheel, and so on. Hooke's 'scapement had a small recoil; the aim of Dutertre was to make a dead beat one of it, in which he succeeded. There is a drawing of this 'scapement in Plate xiv. fig. 4. of Berthoud's *Histoire de la Mesure du Temps*. He says, "that the properties of this 'scapement are such, that sudden shocks do not sensibly derange the vibrations; that the pressure of the wheel-teeth of *arrête* on the cylinders, corrects the impulse that the balance receives from the wheel work, which, on the motive force being doubled, prevents the vibrations from being affected."

In Plate xli. fig. 16. of the first volume of Thiout's work, is a drawing of this 'scapement, modelled for that of a clock, described at page 101. He says, "Fig. 16. is an escapement of the Sieur Jean Baptiste Dutertre, which has only one pallet, on the axis of which is the fork. The two ratchets or wheels are on the same arbor, when the pallet escapes from the small ratchet; the larger one, which is called the ratchet, or wheel of *arrête*, rests on the arbor of the pallet, and leaves the vibration to be pretty free. Plate CCCII. Fig. 7. On the pallet's returning to meet with the teeth of the small ratchet, the pallet-arbor, or cylinder, being notched or cut across into the centre, allows the wheel of *arrête* to pass; and the wheel of impulsion, after getting a small recoil, gives new force to the vibration; so that in two vibrations only one of them is accelerated: Hence it was thought, that the half of the vibrations being *free*, and independent of the wheel work and its inequalities, they would be more correct than others; but experience did not confirm this." This is, then, the duplex 'scapement, or the nearest possible approach to it.

It is more than fifty years since we saw a small spring clock having this 'scapement, made by a very ingenious clockmaker of this place, whose name was Robert Brackenrigg. It may be supposed to have been made a very few years after Thiout's work was published.

In 1727, Peter le Roy gave an account of a 'scapement which he had made, having one pallet on the axis of the balance, and a notch below it, a wheel of *arrête*, and one of impulse, as described in the preceding 'scapement; so that one half of the vibrations were independent of the wheel work. Dutertre claimed the pretended invention of Le Roy, who, finding it not to answer his expectations, gave it up. That Dutertre made the one which is represented in Plate xli. of Thiout, we have no doubt; and there is unquestionable authority, that he brought Dr Hooke's to the improved state which has just been mentioned. It is said, that he had made a free or detached 'scapement; but no account whatever has been given of it.

The duplex 'scapement, as it is now called, was introduced into its native country about thirty years ago or more, under the name of Tyrer's 'scapement, the name, it is supposed, of him who put the last hand to improve that which came in a lineal descent from Dr Hooke. In place of the notch being made right across the arbor, as has been mentioned before, Tyrer's had a very small cylinder or roller, whose diameter was .03 of an inch, into which was made, in a longitudinal direction, a deep angular notch of 30 or 40 degrees. Plate CCCII. Fig. 8. The cylinder was sometimes of steel, but most frequently of ruby. When the points of the teeth of the wheel of repose fall into the notch, they meet with a very small *recoil* by the balance, in what may be called the returning vibration. This goes so far as to make the point of the teeth for a little to leave the notch, at the side opposite to that by which it came in. The balance on returning, is now in the course of that vibration, when it is to receive impulse from the wheel, which takes place immediately on the tooth of the wheel of repose leaving the notch and the small cylinder, and as soon as the tooth of impulse escapes from the pallet,—the next tooth of repose falls to rest on the small cylinder, and so on.

This 'scapement of Tyrer's is much superior to that of the cylinder, or horizontal one; it is almost independent of oil, requiring only a very little to the points of the wheel teeth of repose. It can carry a balance of much greater momentum, and, when well executed, performs most admirably. But there are so many circumstances or minutiæ to be attended to in it, that some of them may at times escape the eye of the most judicious and careful; the watch may stop, and yet the 'scapement be in every other respect as complete as possible. This has often given the wearer cause to complain, and to suspect the qualities of his watch, and hence watchmakers have been induced to abandon this 'scapement, and adopt inferior ones. The pallets of Tyrer's were at first very thin. We frequently urged the necessity of having them made much thicker, and were pleased to see that this was gradually adopted. Why should they not be made as thick as the pallet of a detached 'scapement? There is no 'scapement which requires to have the balance wheel teeth more correctly cut, or the steady pins of the cock and potence more nicely fitted to their places in the potence plate. The minutiæ alluded to were, too much or too little drop of the impulse teeth on the pallet, the 'scapement not set quite so near to beat as might be, the balance rather heavy, or the points of the teeth of repose too much or too little in on the small cylinder. In a good sizeable pocket watch, the wheels having fifteen teeth, the ratio of the diameter of the wheel of repose to that of impulse may be as .520 of an inch to .400, the cylinder .030. The angle of 'scapement will be 60 degrees, taking from the escape of the impulse tooth, to that of the tooth of repose falling on the cylinder; the balance passes 20 degrees of these, before the impulse tooth gets again on the pallet, consequently it has only 40 degrees for the acting angle of the 'scapement. There is a variety of 'scapements in Berthoud's *Histoire*, which appeared in 1802, many of which are of very inferior note to that of Tyrer's, and yet he takes no notice of the latter. This is remarkable, as he surely must have seen it, considering the great number of them which were made.

While Dutertre was engaged with Hooke's 'scapement, an artist in England, whose name is unknown, produced a 'scapement with the dead beat, which seems at that time to have been the great object of pursuit. Julien Le Roy having got one of these watches, showed it to Sully in November 1727, and told him that it was a 'scapement very deserving of notice. Thiout mentions it as a 'scapement of M. Flamenville, having two pallets of repose; and says that it had much attracted the attention of the English watchmakers, who had made it for three or four years. Plate CCCII. Fig. 9. (See page 108, plate xliii. fig. 26. of his first volume.) With our workmen it went by the name of the 'scapement with the tumbling pallets. The axis of the balance had two semicylindrical pallets, whose faces stood in the same plane or centre of the axis; the balance wheel was the common crown wheel one, the teeth of which got a very small hold of the pallets. When escaping from the face of one pallet, a tooth on the opposite side dropped on the semicylindrical part of the other pallet, where it rested during the going and coming of the vibration; getting then on the face, it gave new impulse, escaping in its turn; the pallet on the opposite end of the verge received a tooth on the semicylindrical part, and so on. After having been laid aside for some time, it was of late years taken up by several, who no doubt must have thought well of it. Among these was Kendal, a man possessed of no common talents. He transformed it into one having two crown wheels on the same pinion arbor, the tops of the teeth in the one pointing to the middle of the spaces in the other, and with only one pallet, the diameter of the semicylinder being of any size. (See Plate CCCIII. Fig. 1.) About thirty years ago we had some watches made with this 'scapement, and after a few years trial gave them up. The principle of the 'scapement is good, as long as the parts of it remain unimpaired, and the oil continues fresh; but the acting parts having such a small hold of one another, get soon altered, which causes a great deviation from the rate of time with which it first sets out. They cannot be expected to last long, unless with a diamond pallet, and a steel wheel of the hardest temper.

The *free or detached 'scapement*, is that in which the greater part of the vibrations of the balance is free and independent of the wheels, the balance wheel being then locked; when unlocked, it gives impulse, which only takes place at every second vibration. In Mudge's detached 'scapement, the impulse is given at every vibration. The progress which has of late years been made in improving the detached 'scapement has been very wonderful, when we consider that half a century ago the name of this 'scapement was unknown. The first rude draught of any thing like it, appears to be that of Thiout's, described at p. 110 of the first volume of his work, and shown in Plate xliii. fig. 30, which he calls "A 'scapement of a watch, the half of whose vibrations appear independent of the wheel work, during the time they are made. A hook retains the ratchet or balance wheel; the return of the vibration brings the pallet to its place of being impelled by the wheel; in the returning, the hook is carried outwards, and leaves the wheel at liberty to strike the pallet, and so on. This sort of 'scapement cannot act without the aid of a spiral or pendulum spring"

Peter Le Roy's 'scapement is the next step that was made towards this invention. He contrived it in 1748, and, like Thiout's, it has hardly ever been made use of. Both of them have a great recoil to give the wheel before it could be disengaged, and their arcs of free vibration are not much extended. Berthaud informs us, that in 1754 he made a model of one, which he gave to the Royal Academy of Sciences. Camus, on its being shown to him at that time, told him that the late Dutertre had made and used such a 'scapement, having a long *detent* and free vibrations. Nothing appears now to be known of the construction of Dutertre's, and Le Roy seems to have acknowledged the priority of it to the one he contrived in 1748. "My thought, or invention," he says, "was not so new as I had imagined. Dutertre's sons, artists of considerable repute, showed me very soon after, a model of a watch in this way by their late father, which the oldest Dutertre must still have. This model, very different from my construction, is, however, the same with respect to the end proposed."

The detached 'scapement in Le Roy's time-keeper, which was tried at sea in 1768, is very different from that of 1748.

Berthoud, in his *Traite des Horologes Marines*, published in 1773, has given, in No. 281, an account of the principle on which the model was made in 1754; and, in No. 971, a particular description of the parts composing it, which are represented in plate xix. fig. 4. of that work. It may be somewhat interesting to lay before our readers what is contained in No. 281. "I composed," says he, "in 1754, an 'scapement upon a principle, of which I made a model, in which the balance makes two vibrations in the time that one tooth only of the wheel escapes, that is to say, the time in which the balance goes and comes back on itself; and, at the return, the wheel escapes and restores, in one vibration, the motion that the regulator or balance had lost in two. The 'scapement wheel is of the ratchet sort, whose action remains suspended (while the balance vibrates freely) by an anchor, or click, fixed to an axis carrying a lever with a deer's-foot joint, the lever corresponding to a pin placed near the centre of the axis of the balance. When the balance retrogrades, the first vibration being made, the pin which it carries turns a little back the deer's-foot joint, and the balance continuing freely its course, its liberty not being disturbed during the whole of this vibration, but by a very small and short resistance of the deer's foot joint spring. When the balance comes back on itself and makes the second vibration, the same pin which it carries raises the deer's foot lever in such a way, that the anchor which it carries unlocks the wheel, in order that it may restore to the balance the force which it had lost in the first vibration. This effect is produced in the following manner: In the instant that the deer's-foot jointed lever is raised, the wheel turns and acts upon the lever of impulsion, formed with a pallet of steel which acts upon the wheel, and with another arm which acts on a steel-roller placed near the axis of the balance; and, in the same instant that the wheel acts upon the lever of impulsion, the second arm, which its axis carries, and which is the greatest, stays on the roller, and the motion of the wheel is communicated to the balance almost without loss and without friction, and by the least decomposition of force. As soon as the wheel ceases to act on the lever of impulsion, it falls again, and presents itself to another tooth." "To render the vibrations of the balance more free and independent of the wheel work," continues Berthoud in No. 282, "and diminish as much as possible the resistance it meets with at every vibration, the pin must be placed very near the centre of the balance, so that the lever may not be made to describe a greater course than that required to render the effect of the click perfectly sure, and while the balance turns, and makes its two vibrations, prevent only one tooth of the wheel from escaping; an effect which would be dangerous, by the seconds' hand, which is carried by the wheel, announcing more seconds, or time, than the balance by its motion would have measured. It was the dread of such a defect that made me then give this 'scapement up, which, I confess, seemed to be rather flattering; but it did not give to the mind that security in its effects which is so necessary, particularly in marine time-keepers, the use of which is of too great consequence, to allow any thing suspicious in them to be hazarded."

The principle given here by Berthoud is the same as that of the detached 'scapement now made, although the parts of the model are more complex. This 'scapement had received a variety of modifications under his hand. In 1768, he had five marine clocks planned to have spring detents to their 'scapements, the lifting spring being placed on the roller, or pallet, which received the impulse. These were not finished till 1782. Subsequent improvements, made by the late Mr Arnold and others, can hardly be considered as differing very materially from those of Berthoud. This 'scapement in pocket watches may sometimes come under such circumstances as have been noticed with Tyrer's; but no other can well be admitted into box-chronometers, whether it is made in the manner of Arnold, or in that of Earnshaw. In the 'scapement of Arnold, (see Plate CCCIII. Fig. 2.) that part of the face of the pallet at the point, or nearly so, on meeting the cycloidal curved tooth to give impulse, rolls, as it were, down on this curve, for one half of the angle, and in the other goes up; or it may be thus expressed—the curve goes in on the pallet for the first part of the impulse, and comes out during the last. In making this curve too circular near the point of the tooth, as has been done by some, when the drop is on the nice side, the pallet has to turn a little way before the wheel can move forward, which has sometimes caused stopping; but, where attention is given to the proper form, this is not likely to happen. In that of Earnshaw, (see Fig. 3) the face of the pallet is considerably undercut. Here, the point of the tooth will slide up for the first part of the impulse, and down in the last; in the first it seems to have little to do, and may acquire some velocity in order to overcome the part it has to perform in the last. The face of the pallet being undercut, had been found requisite from experience, as is said, in order to prevent cutting or wearing. In Berthoud's box-chronometers, or time-keepers, the face of the pallet is made straight, or in a line to the centre. One of these, after twenty-eight years going, the greater part of which was from Europe to India, and in the Chinese seas, was put into our hands, and neither the face of the steel pallet, or that of the detent, had the least appearance of being any way marked. This was the more remarkable, as the wheel was uncommonly thin. It must have been made of very fine brass. The wheel had ten teeth; the ratio of the diameter to that of the roller, or pallet, was .530 to .340; the balance weighed 174 grains, and made two vibrations in a second. The balance was suspended by a short and weak spring, which had been broken by some accident before we got it. The length of this suspension spring required to be .9 of an inch, and of so delicate a nature, that many were made for it before the chronometer could be brought any way near to time. It seemed, indeed, to have more influence on the timing than any spiral spring could possibly have. Each of the balance pivots turned between the rollers, which were more than one inch in diameter; and from them and the suspension spring, perhaps, arose that ease and freedom in the motion of the balance, in consequence of which the balance wheel teeth had little to do when impelling the roller or pallet; and this may have been one cause why the pallet face was not cut or marked. It may be observed, that it had the common spiral balance spring, and a compensation consisting of two laminæ, or blades of brass and steel, pinned together and rivetted; and in the moveable end was a screw, which, by its connection with an arm in which the curb pins were placed, served to regulate for mean time. Three screws in the balance were also used for this purpose.

When the diameter of the pallet roller has a considerable proportion to that of the wheel, the angle of 'scapement will be less, and the hold on the face of the pallet will also be less; but the impulse given will be more direct, and the chance of stopping, from any counter-action by external motion, will also be greatly lessened. In this angle more must be included than that which is made from the drop of the tooth to its escaping the pallet. The angle of 'scapement is included between the point where the tooth escapes from the main pallet or roller, and the point to which the lifting-pallet comes in returning, after having passed the lifting-spring. There can be no 'scaping unless the lifting pallet has passed the lifting spring: It is then again ready to unlock the wheel. It is desirable, that the unlocking of the wheel should be made with the least possible resistance to the vibrations of the balance; which is attained, by having the end of the lifting-pallet as near to the centre of the balance as is consitent with its getting such a hold of the lifting-spring, that in its course, it can readily and easily bring out the detent from locking the wheel. The hold of the tooth on the detent should not be more than the hundredth part of an inch. But, in doing this, the supplementary angle becomes greater and increases the angle of 'scapement; and therefore it may be proper to have the lifting-pallet a little longer. A little additional length will greatly reduce the angle of 'scapement, and not much increase the evil of a greater resistance to the vibrations of the balance.

In a box chronometer, where the balance wheel has twelve teeth, and the whole angle of 'scapement is to be 60°, it is required to find the ratio of the diameter of the wheel to that of the roller. The supplementary angle being taken at 15°, the angle of impulse must then be 45°, which is rather wide as otherwise; but it will be less than this, when the thickness of the points of the teeth, and the spaces for drop and escape, are not taken into the computation. Now 360° being divided by twelve, the number of the wheel teeth, gives 30° for the quotient; and again divided by 45, the number of degrees for the angle of impulse, the quotient will be 8°. The diameter of the wheel is supposed to be .6 of an inch. To find that of the roller, say, as 12 : 6 : : 8 : 4. Four tenths of an inch is the diameter required for the roller, which will give somewhat less than 45° for the angle of impulse. The diameter of the roller may be found in another way, sufficiently near for practice. The diameter of the wheel is .6 of an inch, or .600; then say, as 113 : 355 : : .600 : 1.885; this last being divided by 12, the number of the wheel teeth, gives for the quotient .157, the distance between the teeth. This distance taken as a radius for the roller, would give 60° for the angle of impulse. About one-fourth more of this added, will give .200 for the radius, so that the angle may be about 45°.

Nothing should be overlooked, which can contribute to make the balance unlock the wheel with the least possible resistance. When the wheel is locked by the extremity of the teeth, it must be easier unlocked than when the locking is at a less distance from the centre. The unlocking cannot be done easier than with a wheel for such a detached 'scapement as was contrived about fifteen years ago by Owen Robinson, (see Plate CCCIII. Fig. 4) a very judicious 'scapement maker, who wrought long with the late Mr Arnold. This wheel is like that for Tyrer's 'scapement. The long teeth of *arrête* rest on the detent, and the upright teeth give impulse. It is evident that the unlocking with such teeth must be very easy, when compared with the teeth of those wheels which are made after the ordinary way.

Lest what has been said concerning the principle of a detached 'scapement may not be sufficient, we shall endeavour to describe the 'scapement itself, such as it is at present commonly made, so as to give an idea of it, and of the manner by which it acts. The balance-wheel of a pocket chronometer has fifteen teeth not very deep cut, and a little under cut on the face. A notch cut into a round piece of steel or roller, which is thicker than the wheel, forms the face of the pallet. Sometimes a small piece of ruby or sapphire is inserted into the notch at the face of the pallet, for the wheel teeth, to act upon, so that no wearing may ensue. The ratio of the diameter of the wheel to that of the roller, is that of .425 to .175. When the wheel and roller are in their places, the wheel supposed to be locked, the roller must turn freely between two teeth, having only freedom, and not much more. From the centre of the roller to the point of one of the teeth, that next the last escaped, let a line be drawn at a tangent to this tooth. On this line is placed the detent and lifting springs. The detent piece on which the wheel is locked, is a small bit of fine stone, either ruby or sapphire, set into steel, formed into a delicate spring, of such a length as to be equal to that of the distance of two or three spaces between the teeth, with a sole and steady pin at one end, which must be fixed to the potence plate by a screw. This is what is called the *detent spring*, the end of which goes within a little distance of the circle described by the extremity of the lifting pallet. On the left hand side of the detent spring is attached another called the *lifting spring*, which cannot be too delicate, but is made a little thicker towards the outer or lifting end than anywhere else. This end of the lifting spring projects a very little beyond that of the detent spring. On the arbor of the roller and balance, and placed near the roller, is twisted a short and thick steel socket, in which is set a bit of precious stone, the face of which is made flat, and nearly in a line with the centre, behind it is chamfered on towards the point, and made rather thin than otherwise. This is called the *lifting pallet*. The length or height is made so as to unlock the wheel to the best advantage; that is, by only carrying the detent a short way beyond the unlocking. This excursion is to be confined to as small an angle as may be. Near to the detent piece is fixed a stud, in which is a screw to regulate the depth of the detent into the wheel teeth. The point of the screw should be hardened, and have a part of the ruby detent to rest upon it, when the detent spring presses that way. When the balance is at rest, the face of the lifting pallet is very near to the outer side and end of the lifting spring. If the balance is brought a very little about to the left, the lifting pallet will pass the end of the lifting spring. On the balance being now turned towards the right, at the moment of the wheel being unlocked, the main pallet or roller presents itself, to receive the point of one of the teeth, and is impelled with considerable force; meanwhile the detent falls again to its place, and locks the wheel. The balance, having completed this vibriation, returns. In the returning, the lifting pallet pushes the lifting spring easily aside, being no longer supported by the detent spring when turning in this direction, that is, from the right to the left, the detent is again ready to be disengaged on the next return of the balance to the right, and so on.

The detached 'scapement of Mudge was contrived about sixty years ago or thereabouts, if we may reckon from the year 1766, when he showed it to Berthoud, who was then in London, and who informs us that it had been made a considerable time before.

This 'scapement consists of a wheel and pallets, like those made for the dead beat 'scapement of a clock, only the wheel teeth are not cut half the depth. On the verge or arbor of the pallets is placed an arm of any length, generally a little more than that of the pallets. (See Plate CCCIII. Fig. 5 ) The end of the arm is formed into a fork-like shape. On the axis of the balance is a short pallet, whose acting end may be of a small circular form, having the sharp part of the angles blunted, coming a little way within the prongs of the fork, which alternately acts, and is acted upon. There is also on the balance axis a small roller, having a notch in it. On the end of the arm is attached a small steel piece or index, in a plane which may be either above or below the prongs of the fork; this index is on the outside of the roller, when the free part of the vibrations is performing, and prevents the wheel teeth from getting away from the place of rest. On the return of the balance, the index passes with the notch in the roller to the opposite side. Meanwhile the short pallet gets into the fork, meeting with one of the prongs, pushes it on a very little way, and thus disengages the teeth of the wheel from the circular part of the pallet, where they rest during the free excursions of the balance. During the disengaging, the teeth get upon the flanch of the pallet, and give impulse, which causes the opposite prong of the fork to come forward on the short pallet, and communicate impulse to it. In Mudge's 'scapement, as drawn in the plate for the work published by his son, there are two short pallets, and the prongs of the fork lie in different planes. The impulse in this 'scapement is given at every vibration; and it seems to have done uncommonly well, particularly in the watch which he made for her Majesty Queen Charlotte. It is by no means suited for the execution of ordinary workmen, as it requires more address than usually falls to their share. The late Emery was much taken up with it; and although he had a little success, and had the aid of a very excellent hand, yet he experienced considerable difficulties. It might be somewhat easier managed, by adopting Lepaute's mode of Graham's dead beat, which we have tried.

In 1792, a very neat and ingenious detached 'scapement was contrived by the late Howells, founded on that of Kendal's, (in whose hands he had occasion frequently to see it,) in which the wheel teeth rested on the cylindrical part of the pallet, during a part of the going and returning vibrations of the balance. See Plate CCCIII. Fig. 6. In the other, after impulse is given on the face of the same semicylinder, and just before the tooth is quitting it, a detent is presented to receive one of the wheel teeth, by which the action of the wheels is suspended during the greater part of the going and returning vibrations, the pallet being then free and independent of the wheels. This 'scapement is composed of two crown wheels on the same arbor, the points of the one being opposite to the middle of the spaces of the other. On the axis or verge of the balance, which stands quite close to that of the balance wheels, is a semi-cylindrical pallet, whose diameter should be according to the angle of 'scapement required, which will also regulate the distance of the wheels from each other. The pallet is put near to the collet on which the balance is rivetted; a small arbor, having very fine pivots, is run in so as to stand parallel with that of the balance, and placed at some distance outside of the wheels, but where a line drawn from it, and passing at equal distances from the points of the wheel teeth, when continued, shall fall in with the centre of the balance; on this arbor is fixed an arm, at the end of which is a small fork and index; on the verge or balance axis, and near the lower end, is a short pallet, and a roller connecting with the fork and index, in imitation of Mudge's, acting in the same way as has been described, but only in the locking and unlocking part. Where the arm passes between the wheel teeth, which may be at ninety degrees or so from where they act on the pallet, are fixed two detent pieces, one for each wheel, opposite to the arm, and in the same line. A part of it is prolonged beyond the arbor outside, by way of a counterpoise, where two screws in fixed studs serve here as a banking to it. It may easily be conceived, that one of the wheels being locked, suppose that on the left, the balance, when returning from the left to the right, will, by means of the short pallet and forked arm, &c. carry the detent away; and just as the point of the tooth is free, the face of the semicylinder is presented, to meet with a tooth of the same wheel, and get impulse; but before this tooth has nearly escaped, the detent is ready to receive a tooth of the opposite wheel, and so on. This 'scapement gives an impulse at every vibration, as is done in Mudge's. In the tenth volume of the *Transactions of the Society for the Encouragement of Arts, &c.* there is a description and drawing of it. It may be observed, that were the semicylindrical pallet faced with a piece of precious stone, the 'scapement would go on for a considerable time without falling off.

In the marine keepers which Mr Mudge himself had made, the 'scapement is on a very flattering principle, which he suggested as the means of improvement many years before he put it in practice. Its good performance seems to have been unequalled; and it is singular, that, notwithstanding the efforts of three or four of the best hands that could be got to the establishment set up by Mr Mudge, junior, in order to put these 'scapements to timekeepers which they were employed to make, not one was ever produced that was at all equal to the original ones. The 'scapement is *apparently* very complex, elaborate, and of course expensive in making; yet, when once executed, it will be permanent in its effects, and require no after adjustment like the common detached one. After what has happened, it is not likely that it will be again adopted. The basis of it is that of the curious old crown wheel and verge. In place of the verge being in one, having two pivots and the balance rivetted on it, let us conceive that each of the pallets of the verge has an arbor and two pivots, and that the balance is on a double kneed crank, having a pivot at the end of each knee, one being near to the foot, the other near to the collet on which the balance is rivetted; these pivots, and those of the pallet arbors, are in one upright line, coinciding and concentric with one another, having their motion, as it were, free and independent of each other, unless when in a part of the action of the 'scapement; the face of the pallets, in place of being flat, are hollow, or a little curved, having a nib at the edge to lock the wheel by. On the lower end of the lower pallet arbor is an arm projecting nearly as far as the bending of the crank knee, in which is fixed a pin that acts on the inner side, and near to the end of the arm, and is alternately acted upon; close by the arm, and on the pallet arbor, the inner end of a spiral spring is fixed; the outer end is in a stud, having a certain tension or bending up before fixing in the stud. The upper pallet arbor has the same as has been described to the lower one, and a pin in the upper knee of the crank. It may easily be conceived, that the length of the crank knees ought to be such as to allow it to sweep round and behind the crown wheel, its boundary or banking being that of the crown wheel arbor, or its pinion arbor. When the pallets are not raised up, and the wheel unlocked, the tendency of the spiral springs is to bring them down within the spaces of the crown wheel teeth. Suppose the upper pallet raised up, and the wheel locked, the under one being in the reverse position, and the balance vibrating towards the right, the pin in the upper crank will, of course, meet with the small arm, and carrying it on a little way, the wheel-tooth gets disengaged, by which the wheel getting forward, the lower pallet is raised up, and the wheel is again locked. In the interim, the upper arm being carried on a few degrees, by means of the momentum of the balance in vibrating, bends up the spiral still more than what was done by the wheel raising up the pallet, the re-action of which, in the returning vibration, gives impulse by means of the arm on the pin of the crank. The pin in the lower crank now getting forward, meets with the arm of the lower pallet arbor, carries it on, the wheel gets disengaged, and so on. This 'scapement cannot set itself off; for before this can be effected, the balance must get some degree of external circular motion in its plane. The balance may be said to be free in that part of the vibration, after the pin of one crank has left its corresponding arm, till the pin of the other meets with its arm; this is, however, very momentary. The balance had on its arbor two spirals or pendulum springs, for the purpose of obtaining the most isochronous vibrations. Something in this way had been proposed by one of the Bernoullis. Drawings and a description of this 'scapement will be found in the work published in 1799, by Mr Thomas Mudge, junior. The compensation, like every thing of Mudge's, is ingenious, though nothing of this kind can ever be equal to that of being in the balance itself. The train of wheels went contrary to the ordinary direction, and we have no satisfactory reason assigned for it.

Although the balance in pocket watches may be put very well in equilibrium, yet many things contribute to make them go unequally in different positions, such as in hanging, laying, &c. which require time, and give a great deal of trouble, before they can be completely corrected. In order to get the better of this, Breguet, an eminent watchmaker in Paris, contrived a 'scapement, which, with the pendulum spring stud, revolved round the centre of the balance once every minute. By this means, whether the balance was in equilibrium or not, the going of the watch was little affected by it, as every part of it was up and down in the course of a minute, which compensated any want of equilibrium. This contrivance is merely mentioned by Berthoud in his *Histoire*, as he did not think himself at liberty to give any description of it, since Breguet had a patent or *brevet d'invention* to make them. We have heard it said that the same invention had been made before by the late Mr John Arnold.

Those who wish for farther information respecting 'scapements, may consult *Traité d' Horlogerie* par M. Thiout, *Histoire de la Mesure du Temps*, par M. F. Berthoud, and the *Transactions of the Society for the Encouragement of Arts, Commerce, &c.*

## CHAP. II.

### *On Compensation Balances.*

Compensation against the effects of heat and cold in time-keepers, has been one of the greatest improvements that could have been applied to them. Without this they would have been far from keeping time, and would have varied continually with the temperature of the atmosphere, so that no fixed or settled rate could have been obtained. The detached 'scapement will show this more than any other; for if there is no compensation to it, the watch will vary nearly thirty seconds in twenty-four hours. The influence of oil on the cylinder 'scapement becomes in itself a sort of compensation, and the effect of changes of temperature is much less obvious in it than in the detached 'scapement. There is very great reason to believe that Harrison was the first who applied a compensation; but there are no written documents to warrant us in ascribing to him the honour of the invention, to which, however, we think he has a just title. Some very imperfect hints had been given by Martin Folkes, Esq. President of the Royal Society in the year 1749, of Harrison's having some mechanism of this sort in the three time-pieces which had been made prior to the fourth, which gained the reward voted by parliament. But as no description of it was ever made public, the French artists have had it in their power to claim a priority in the invention. In Harrison's fourth machine, it is known that the compensation piece in it was composed of laminæ of brass and steel, pinned and rivetted together in several places. Perhaps those in the three former differed little or nothing from this.

The first pocket watch made in Europe with a compensation was by F. Berthoud. It was begun in 1763, and finished in the beginning of 1764; and was sold in London in 1766, to Mr Pinchbeck, for his Britannic Majesty King George the Third. The compensation was effected by laminæ of brass and steel pinned together; one end of which being fixed to the potence plate, the other acted on a short arm from a moveable arbor, a longer arm having the curb pins in it, being made to move nearly in the circle of the outer coil of the spiral spring. It had a common crown wheel and verge 'scapement, and a going in time of winding. The balance was so heavy as to set, being sixteen grains in weight, and the vibrations were four in a second. Mr Kendal adopted this mode of compensation in some of his pocket watches.

Mudge, some time before the year 1770, made a watch for Mr Smeaton, in which the compensation was effected by two long slips of brass and steel soldered together: being dressed up, it was turned up into a spiral, as close together in the coils as to be free, and no more. The inner end was fixed to a circular curb-wheel, a short portion of the outer end had a pivot, bent in the circle of the outer coil, and supported by a small stud, through a hole of which it moved freely; at this end was the curb pins, between which the spiral or pendulum-spring passed; the effect of heat or cold on it was counteracted by the spiral compensation piece. The 'scapement of this was the cylindrical one; and so long as the oil kept clean and fresh, the compensation might be useful to it. In 1774, we made one or two of the same sort for horizontal watches. At that time no better 'scapement and compensation were known, at least so far as came under what was then the common practice.

In the voyage undertaken for the trial of Le Roy's Time-keeper in 1768, and published by Cassini in 1770, along with the description and drawings of it, Le Roy has given that of a compensation balance, which is exactly like those of the present day, only the laminæ are pinned together, in place of the brass being melted on the steel. Plate CCCIV. Fig. 1. The compensation of the time-keeper, however, was not of this kind; it consisted of two glass tube thermometers, bent nearly into the form of a parallelogram, with a small ball at one end to each, the other open, and filled partly with mercury, partly with spirit of wine, fixed to the axis of the balance opposite one another: the balls lay very near to the axis. It would appear that Le Roy had not thought of a metallic compensation, until the return of the time-keeper from the voyage of trial. He had taken the idea of this from getting an account of Harrison's, which was sent to the Royal Academy, signed by Ludlam, who was one of the scientific gentlemen appointed by the Commissioners of the Board of Longitude to take Harrison's account of his time-keeper, previous to any part of the reward being paid him.

In a life of Peter le Roy, the son of Julien, the method of compensation is erroneously ascribed to that artist's father, to whom "we are indebted," says the writer of the article, "for the method of compensating the effects of heat and cold on the balances of chronometers, by the unequal expansion of different metals; a discovery which has been brought by our English artists to a state of great perfection, although it had been laid aside by the inventor's son Peter."

It is difficult to understand how this mistake should have been committed; for the following account of the discovery, given by Peter le Roy himself, is in direct contradiction to the preceding statement.

"Observation V.—*Sur la compensation des effets de la chaleur et du froid*

"Selon la gazette du commerce, et la rapport *signé* Ludelam, envoyé à l'academie: pour remedier aux irregularités produites dans les montres marines par la chaleur et par le froid, *M. Harrison se sert d'une barre composée de deux pieces minces de cuivre et d'acier de longeur de deux pouces, rivées ensemble dans plusieurs endroits, fixées par un bout, et ayant de l'autre deux goupilles au travers desquelles passe le ressort du balancier. Si cette barre reste droite dans le tems temperé (comme le cuivre recoit plus d'impression de la chaleur que l'acier,) le coté de cuivre deviendra convexe au tems chaud, et le coté d'acier le sera au tems froid. Ainsi les goupilles fixent tour-à tour les parties du ressort, selon les differens degrés de chaleur, et l'alongent ou le racourcissent: d'où nait la compensation des effets du chaud et du froid.*

"Si j'avois connu cette ingenieuse methode avant d'avoir pensé à mes thermometres, je n'aurois vraisemblablement point hesité à en faire usage dans ma machine.

"J'ai balancé quelque tems, si je ne devois pas lui donner la preference. J'ai même fait quelques essais dans cette vue. J'en parleroi bientôt: mais apres y avoir pensé murement, et avoir mis à part, autant qu'il m'a été possible, ce penchant qui nous parle en faveur de nos productions, mes thermometres m'ont paru préférable," &c. &c.

See *Memoire sur la meilleur maniere, de mesurer le tems en mer*, p. 55, 56, inserted at the end of *Voyage fait par ordre du Roi, in* 1768, *pour éprouver les montres marines inventées par M. le Roy*, &c. par M. Cassini, fils, Paris, 1770.

As must always be the case in the infancy of any branch of science, various methods are fallen on before it arrives at its most improved state. Berthoud, Arnold, and others, had recourse to different modes of compensation before they arrived at the one which gave them complete satisfaction. The former, in his first machines, used small wires of brass and steel, combined nearly like the gridiron pendulum, to effect the purpose of compensation; to those of a later date, was applied a straight piece, Plate CCCIV. Fig. 2; composed of laminæ of brass and steel pinned together, acting on the short arm of a lever. In the end of the other arm, which was long, the curb pins were fixed. Even with those balances which were afterwards made, and composed of brass and steel pinned together, he adopted as a supplementary aid, the straight compensation piece with the moveable arm and curb pins. Fig. 3. Considering the talents he possessed, and the great experience which he must have had, this seems a little curious; as we think, where there is a complete compensation in the balance, it *alone* should be sufficient, and that the curb pins would tend to disturb the pendulum spring rather than give any aid to the compensation. The more free the pendulum spring is, the chance is more in favour of good performance, when the compensation balance is supposed to be fit and complete for what is required. In some of Arnold's balances, two pair of laminæ were placed parallel to the diametrical arms; on the middle of them was fixed a small wire which came through the rim, outside of which, and on the end of the wires, a small ball was fixed to each. Fig. 4. These balls were pushed out or drawn in by changes of temperature. The arguments given in favour of such as Earnshaw's, which are turned first on the steel, and again on the brass, after being melted on the steel, are certainly very strong and convincing, and nothing can well be said against them, and yet there appears to be a softness in such a balance, that cannot exist in those where the laminæ are set or turned up by hand. Fig. 5. There is undoubtedly a great deal more trouble in making the last, and though it has been said that they cannot be true or round when made in this way, yet we have seen some of those done by Owen Robinson, as round and true as any turning could make them, and possessing a degree of stiffness that cannot exist in the other; they have been even unscrewed, or taken to pieces, and again put together, without altering the rate of the chronometer. After all, we are not aware that cronometers with the one balance actually perform better than those with the other.

It may be observed, that on the rim of the turned balances, which is separated into two, there are small pieces of brass, made to slide backwards and forwards, according as it may be found requisite, when under the process of adjusting for heat and cold. In the other, this is done by screwing backwards and forwards the pieces of brass which turn spring tight on small screws left at the outer end of the laminæ, and are bent in the same circle with them. Both balances have what are called meantime screws, placed in the vertical line of the hanging position, which serve to adjust them to their rate of time, &c. We have seen and made compensation balances with three arms, and three pieces, and three meantime screws, which were stiff, and answered very well.

## CHAP. III.

### *On Balance or Pendulum Springs.*

The invention and application of the spiral spring to the balance of a watch is, by the foreign artists in general, ascribed to Huygens, while they admit the idea of a straight spring having been long before this applied by Dr Hooke. It was in 1658 that Dr Hooke observed the restorative action of springs, when he put one to the balance of a watch, and applied for a patent to secure his right of invention. The profits were to be divided between himself, Sir Robert Moray, Mr Boyle, and Lord Brouncker. It was not carried into effect, in consequence of a quarrel between the parties, on account of a very unreasonable demand on the part of these gentlemen. Nor was it till 1674 that Huygens claimed the same discovery. Hooke charged Huygens with plagiarism, through the intervention of Mr Oldenburgh, Secretary of the Royal Society, who communicated to him, when he was twice in England, the registers of the society, and also corresponded with him upon the subject. In 1665, Sir Robert Moray requests Oldenburgh to tell Huygens that such watches had already been made in England, and to ask him if he does not apply a *spiral* spring to the balance arbor? It may be asked, where had Sir Robert seen a spiral spring? The natural answer is, that he must have seen it in the hands of Dr Hooke.

On nothing does a chronometer depend so much as in the good quality of the pendulum spring: great as the power of the rudder is, in controuling and regulating the motion of a ship, it is not more extraordinary than that of this spring, in regulating the motions of a chronometer, and we may be allowed to say, that it possesses something like *invisible* properties. It may be set so as to make the machine go fast or slow, in any position required, while neither its length, nor the weight of the balance, are in any way altered. Le Roy thought that he had made a great discovery, and it must be granted to be one, when he found, "that there is in every spring of a sufficient extent, a certain length, where all the vibrations, long or short, great or small, are isochronous; that this length being found, if you shorten the spring, the great vibrations will be quicker than the small ones; if, on the contrary, it is lengthened, the small arcs will be performed in less time than the great ones." Notwithstanding this condition of *sufficient extent*, the isochronous property will remain no longer than while the form of the spring is preserved, as it originally was. Should the coils be more compressed or taken in, the long vibrations will now be slower than the short ones; and, on the contrary, if they are more let out or extended, the long vibrations will be faster than the short ones. A more general principle for obtaining the quality of isochronism may be applied, by making the spring act proportionally, in an arithmetical progression, according to its tension. Every five degrees of tension should make an equilibrium with a given force or weight of ten grains, that is 5, 10, 15, 20, &c. degrees of tension, should be balanced by 10, 20, 30, 40, &c. grains. To try small springs by this process would require a very nice and delicate tool. In order to obtain these properties in pendulum springs for his timekeepers, Berthoud made them thicker gradually from the outer to the inner end; our old English way is the reverse of this. Whatever may be the form of the spring, whether flat or cylindrical, the best and most direct way is to try them in the timekeeper itself, by taking four hours going, with the greatest force the main spring can give, and then four hours with the least. It is of consequence to have these springs hard, or well tempered.

## CHAP. IV.

### *On the Jewelling of Pivot Holes.*

Our chronometers, from the art of jewelling the pivot holes, may be said to have acquired a durability and character, which they would not have otherwise received. It must not be imagined that there is any time-keeping principle or improvement in a jewelled hole more than in a brass one; and, notwithstanding what has been said in favour of the last, few will be hardy enough to run the hazard of having the balance, and balance wheels, to move in brass holes. It is very well known, that in a common verge watch, where the balance holes are jewelled, its motion will be kept up for a longer time than when it runs in brass holes. The friction at the balance holes cannot be supposed to be less than at those of the fusee; for, in the time of one-fourth of a turn of the fusee, the balance must make more than what is equivalent to 9000 revolutions Berthoud regretted much that he had not an opportunity of getting the pivot holes of his timekeepers jewelled; yet, from that versatility of genius which he possessed, he supplied admirably the want of this, in a manner that very few could have equalled. Some of the balances in his time-keepers were made to give six vibrations in a second, while others gave only one. His number *eight* made one vibration in a second, and was the one which gave the best performance of all those that he had constructed. It seems to have been considered as a wonderful discovery, that jewelled holes wore down the pivots, and thickened the oil, after they had been used for upwards of a hundred years. How came this not to be sooner observed, when so many were engaged in making chronometers, and that too in considerable numbers? That pivots, from a length of time, even with good oil, and with greater probability from bad oil, may have got, as it were, glued in their holes, there is little reason to doubt; but this never arose from particles wearing away from either the steel or the stone, by the friction of the pivot. Let any one try to whet a graver, which requires some degree of force, on a polished Scotch pebble, for instance, and they will find that no exertion whatever will make the graver bite the stone, or the stone the graver: for where any effect of this kind takes place, it must be nearly mutual. The hardness of the Scots pebble is well known to be much inferior to that of the ruby or sapphire. After being exposed to the air for a considerable time, oil gets viscid and thick, which arises, as has been observed by chemists, from its absorbing or attracting oxygen. We suspect that oil, from this cause *alone*, may become more glutinous at a jewelled hole than at a brass one. By its application to brass it soon acquires a bluish green tinge, as if something acted upon it. This is owing to the metal becoming oxidated by the joint action of the oil and air. The oxide thus formed combines with the oil, and forms a metallic soap, which is much less tenacious than that formed at a jewelled hole. By the continuation of this process, the hole in brass in time becomes wider, and the oil disappears, leaving the pivot and hole in a greater or less degree wasted; and, instead of the oil, we have the metallic soap, which has hitherto been considered as rust. To be convinced, however, that this is not the case, we need only attempt to wipe it off from the pivot, from which it easily parts, and which it would not do were it really rust. Oil, however, can have no action on the jewelled hole, and any change that is effected by the oil must be confined to the steel pivot, on which its action is so exceedingly slow, that a great length of time must elapse before the oil is decomposed and disappears; and hence what has been called rust in a brass hole, is seldom or never met with in a jewelled hole. If a little fine Florence oil is put into a small phial for about two-tenths of an inch deep, and remain for a few years, it will become exceedingly viscid and glutinous, and will be intermixed with parts tinged with red of various shades.

The same appearance is sometimes seen at jewelled pivot holes, and has been erroneously supposed to be produced by the operation of the pivot on the hole. It is singular that oil will act more forcibly on fine brass th n on the common sort, or even on copper; a metallic soap somewhat resembling verdigrease will soon show itself on the former, while the latter will have no appearance of being injured. But we are not to infer from this, that copper holes would be preferable to those made in fine brass; for although the oil in this case would be more durable, from its acting more slowly on copper than on brass, yet the increase of friction from the copper would more than counterbalance this advantage. It can hardly have escaped the eye even of the most indifferent observer, that oil acts more readily and forcibly on new than on old work. On the former, it will frequently show itself in the course of 24 hours. Oil varies so much in its quality, that some will become so thick and viscid in the course of a few months, as to stop the machine altogether. This has occurred in the experience of a very celebrated artist, who informs us that "his regulator, which has been found to go to a greater degree of accuracy (though not to a second in two months, as has been said of others) than even that at Verona, as observed by the astronomer Cagnoli, or that at Manheim, as observed by Mayer, was found to perform very indifferently after being cleaned, and at the end of three or four months stopped altogether, which arose from the application of bad oil." We are of opinion, that where the pivots are small, and the revolutions of the wheels quick, jewelled pivot holes are the best. It will not be an easy matter to do without oil, particularly in pocket or box chronometers, although astronomical clocks or regulators may be so constructed as not to require it.

## CHAP. V.

### *On the Machinery for going in time of Winding.*

The earliest machinery for going in time of winding is the simplest and best that has yet been produced; although, upon the whole, it may not be so convenient in its application. In the old thirty hour clocks, the first wheel of the going part had on its arbor a fixed jagged pulley A: (See Plate CCCIV. Fig. 6.) On the arbor of the first wheel of the striking part was a moveable jagged pulley H, with click and ratchet to it. Over these, and through or under the pullies of the counter weight *p* and main weight P, went an endless cord, woven either of silk or cotton. Both parts of the clock were carried on by a single or main weight; and, when winding it up, this was done by the striking pulley; by which means, the weight acted constantly on the going part. This is a method which we adopted in some common regulators, and afterwards found it was the same that Berthoud had used in some of his. The moveable and winding up pulley with its ratchet was on a fixed stud, having a click and spring, which were fixed to one of the plates, as was also the stud. The other pulley was on the arbor of the first wheel, and fixed to it. The only inconvenience and objection to this contrivance, particularly in eight day clocks, arises from the wearing of the cord on the jagged part of the pullies, which produces a great deal of dust, and makes the clock get sooner dirty than it would do, if this was effected in a different way. In clocks which go a month, or six months, as some of Berthoud's did, this will be very much obviated, particularly with a fine and well wove silken cord.

There is a very ancient way of going while winding, which was long applied to the fusees in clocks and watches. On the inside of the great wheel is another wheel, whose teeth are cut to look inward to the centre, upon which acts a pinion of six, which runs in the bottom of the fusee, and is turned round with it. The fusee arbor is free within both the great wheel and the fusee; upon it is fixed the fusee ratchet, and a wheel with about half the number of teeth of those in the inward toothed wheel. It is evident, that if the fusee arbor is turned round, the wheel fixed on it, which acts also into the pinion of six, will by this make the pinion turn; and this again, acting on the inside wheel teeth, will apply as much force to it as the fusee requires in setting up. When wound up, the click in the great wheel, as in the ordinary way, stops the fusee by the ratchet from running back. This method takes six times longer of winding up than by the common way; and the great strain which is laid on the pinion and inside wheel teeth soon destroys them. With a little more apparatus, a fusee of this kind can be made to wind up whichever way the arbor is turned; hence it got the name of the *drunken fusee* (See the particulars of it in *Thiout*, vol. ii. p. 383. and Plate xxxviii. Fig. 14.)

A going in time of winding, of later application to clocks and regulators, consisted of an arbor within the frame, on which was a pin, and an arm inside, with a nib and deer's foot joint; another arm on the outside when pulled down, served to make the jointed nib rise and pass the third wheel teeth; a spring acting on the pin brought the nib in a contrary direction, to act on the third wheel teeth, by which it gave motion to the swing wheel during the time of winding, and continued to do so until getting clear of the teeth.

The general method which is now adopted, both in clocks and chronometers, consists of an auxiliary spring, ratchet, and detent. In clocks, two springs are somewhat used; being doubled round, are screwed by one end to the back of the auxiliary ratchet; the other end is made to act against the arms or crosses of the great wheel. On the opposite side is the click, which acts with the barrel ratchet; and when the force of the weight is taken off by winding up, the force of the springs act on the great wheel, and not being allowed to bring the auxiliary ratchet forward, which they would do; but this is prevented by the detent, consisting of an arbor whose pivots run in the frame, and an arm acting against the face of the small teeth in the auxiliary ratchet.

When this method is applied to a clock or watch fusee, there is a circular and flat steel spring screwed or made fast by one end to the inside of the great wheel; in the other end is a small hole, opposite to which is made a short and circular slit in the great wheel. A pin in the auxiliary ratchet is placed so as to correspond to the hole in the spring and the slit in the great wheel, through both of which it comes; the slit gives range for the bending up of the spring. When the force of the main spring does not act on the fusee, which is taken off when winding up, the auxiliary ratchet and detent, which has a slender spring to keep it to its place, serve the same end as has been described for the clock.

The mechanism of this going in time of winding, was first exhibited by Harrison in his time-keeper, when explaining its principles to the commissioners who were appointed to receive them. It has been said that he took the idea of it from having seen an analogous contrivance in an old kitchen jack, where it had been applied to keep the spit turning while the jack was winding up. There has been a great deal of ingenuity displayed even in jack-making.

It is singular, however, that it was never thought of to apply vanes or wings to the fly, which could have been set so as to regulate the velocity according to the greater or less weight with which the spit might be loaded ; but, simple as the setting of these wings would be, it might not be so easy to prevail upon the cook to take the trouble of either understanding or using them. The water-jack, which has been known in this country for more than seventy years, is very convenient in this respect, as it is so easy to make the discharge of water at the cock to run full, half, or quarter, on the small kind of mill-wheel which drives the whole of the machinery belonging to the jack.

A great many years ago, we contrived an easy way of making a going in time of winding for a clock, to several of which it was applied. The third wheel has a socket (with a small shoulder) truly fitted to it, the hole being soundly and smoothly broached. That part of the third wheel pinion arbor, which works in the socket, must also be truly turned, and made as smooth as any pivot, so as to be free, easy, and without shake. The end of the socket, which is not in the wheel, should be smooth and flat ; its diameter outside about three-tenths of an inch, and to apply to a flat smooth steel shoulder formed on the pinion arbor. On the side of the wheel opposite that on which the socket shoulder is placed, let there be fixed a small steel pin, distant from the centre about three-tenths of an inch, the height of it being about one-tenth. Make a piece of brass so as to have a fine small ratchet wheel on it, of about four-tenths of an inch in diameter, with a sort of hoop or contrate wheel rim on one side of it, three-tenths and a half in diameter inside, the thickness being a little more than that of an ordinary contrate wheel of a watch, and the depth one-twentieth of an inch. The ratchet wheel and hoop have a socket common to both, which is twisted on the third wheel pinion arbor ; this socket on that side of the hoop inside, is the smallest matter lower than the edge of the hoop ; on this part of the socket is fixed the inner end of a small and weak spiral spring, of two or three turns, the outer end having fixed to it a small stud, with a hole in it, that goes over on the steel pin of the third wheel, which works in a short circular opening in the ratchet wheel or bottom of the hoop, of a sufficient range for the spiral spring to keep the clock going during the time of winding up. The detent for the ratchet has one of the pivots of its arbor in the back frame plate, the other runs in a small cock attached to the inside of this frame plate, and sufficiently clear of the third wheel on that side. The edge of the hoop, when the socket is twisted home, should allow the third wheel to have freedom during the action of the spiral spring on it. In applying this going in time of winding apparatus to a clock, it will easily be seen in which way the small ratchet teeth must be cut, and also in which way the spiral spring must exert itself. During the action of winding up, this allows the minute hand to make a retrograde motion, but it resumes its place as soon as the weight is at liberty.

In the early part of the last century, a considerable intercourse was carried on between Holland and Port Seaton, by the ship owners of Prestonpans, in East Lothian. Among the imports, was old iron in hogsheads, and many of the articles were little worse for being used, as, by a law with the Dutch, no iron work was allowed to be repaired. Among the things which came home were some camp jacks, of a very ingenious construction, and evidently of German origin. Two or three of them, one of which we have seen, are still in that neighbourhood. It was composed of the usual wheels and pinions, endless screw, and a small fly, rather weighty. The frame mounted on an upright stand, was about four feet or more in height. A thin and narrow iron bar, of four or five feet long, was attached to the stand, and could be made to slide up and down on it, nearly the whole four or five feet ; one edge of it was toothed like a straight rack, and worked into the pinion of the first wheel, by means of a weight or weights hung on a hook at the lower end of the bar ; when the weight and bar came to the lowest point, it was easily moved up to the greatest height, when the jack was to be wound up. The pinion had a hollow socket, and could turn freely round the arbor of the first wheel ; on the lower end of the socket was a ratchet which rested on the first wheel, where the click and spring was placed to act with the ratchet, which by the hollow socket allowed the pinion to turn freely backward when winding up ; on the weight being allowed to act on the rack, all the wheels were made to turn the proper way, and so on. An idea occurred to us, that, in place of the rack moving, a machine might be made to go by its own weight, by means of a pinion turning down on the toothed edge of a fixed rack. A scheme shall be given for a box chronometer of this construction, which supersedes the necessity of either fusee, barrel, spring, or chain. A contrivance of a similar kind has lately been communicated to the Society of Arts in Paris, by M. Isabelle, and is described in the *Bulletin de la Société d'Encouragement*, No. 52. The same method, which has been known for a considerable time, is used at Liege by Hubert Sarton, who makes eight day spring clocks on this plan.

On the arbor of the first or great wheel is fixed what may be called the fusee ratchet, working with the click and spring, which are on the auxiliary or going ratchet ; in the last is fixed a pin, which comes through the end of the auxiliary spring, and the circular notch in the great wheel, which is keyed on in the same way as in the case with a fusee ; and having also a detent and spring for the going ratchet, the whole forming the great wheel, and the mechanism for going in time of winding. On the great wheel arbor, close to the main ratchet, let a small bevelled wheel be fixed, of any small number of teeth, fully stronger than those in the great wheel, the back of the bevelled wheel lying against the main ratchet : indeed both might be made from one and the same piece of brass. Supposing the diameter of the pillar plate to be 2.25 inches, that of the great wheel would be 1.5 inch, and the number of teeth 72 ; the bevelled teeth being half an inch in diameter, would admit 24 teeth ; and if made a little thicker than the great wheel, the teeth would be sufficiently strong. Another bevelled wheel, of the same diameter and number of teeth as the other, is fixed on a pinion arbor, (a hole being made in the potence plate, to allow the bevelled wheels to pitch together,) which is placed within the frame in a horizontal direction, in that line which passes through the centres of the great and second wheels ; one of the pivots runs in a cock, inside of the potence plate, and placed near to the great wheel arbor ; the other, which is a little beyond the pinion head, runs in a cock fixed on the outside of the potence plate. This pinion has sixteen leaves, of the same strength as the teeth of the bevelled wheels, and runs in with the edge of a toothed rack ; every revolution will be over the length of one inch on the rack, and equal to four hours, or one turn of the great wheel ; the second wheel pinion being 18. The length of rack, supposed to be 8 inches, would allow the time of going to be equal to 32 hours, 8 inches multiplied by 4 being equal to 32. Were the rack 12 inches long, it would admit the time of going to be 48 hours ; or the diameter of the pinion might be increased from .333 to .500 parts of an inch, and the time of going would then be somewhat more than 30 hours. Let a slip of wood be made 15 inches long, $\frac{5}{8}$ths of an inch broad, and rather more than $\frac{1}{4}$th thick; on one side of this, and close to the edge, let another slip of the same dimensions, but not quite so broad, be set on edge at a right angle to the side of the other; this will form a pattern to have two such cast in brass from it; after being dressed up, one is left plain, the other so as to have twelve inches of teeth made on one of the edges; the plain one is screwed to the inside of the case, and the other is screwed on to the plain one, having the toothed edge on the right hand side of the pinion, so as to make the second wheel and pinion turn the proper way. To the ring or cap which incloses the movement of the chronometer, are attached three pieces of brass, kneed up at each end; the distance from the ends is about two inches and a half, in which are holes made quite parallel to one another, and go on three steel rods, 15 inches long and $\frac{2}{10}$ths of an inch in diameter, fixed in the lower and upper ends of the case, and parallel to one another, and near to the dial of the chronometer. The case may be either of wood or brass, having a door on one side, which serves the purpose of getting at the chronometer, either to observe the time, or to push it up after it is nearly run down. In the lower part of the cap, a recess may be made to receive any additional weight requisite to load the chronometer with, in order to give greater extent of vibration to the balance; the upper part of the case should, if necessary, be hung in gimbols, and the lower end loaded with lead to keep it steady. A chronometer might be easily fitted up in this way to go eight days, by giving more length of rack, a greater weight to the bottom of the cap, more teeth to the bevelled wheel which is on the horizontal pinion arbor, fewer to that which is on the arbor of the great wheel, and the second wheel pinion to make more revolutions for one turn of the great wheel. Suppose the great wheel 80, and the second wheel pinion 16, one turn will be equal to five hours; the bevelled wheel which is on it (being 16) will have a revolution also in five hours; the bevelled wheel which turns it, having 24 teeth, will make a revolution in seven hours and a half. The rack being 25.6 inches long, the pinion of 16 making a revolution on it in seven hours and a half, and $25.6 \times 7.5 = 192$, the number of hours in eight days. The length of the case, being thirty inches, could be no inconvenience where eight days going without winding is obtained. A similar, and we think a preferable, construction might be adopted, by having the chronometer fixed, and a weight hung to the lower end of the rack, which, as in the case of a jack, would keep up the motion required for the chronometer. This plan, however, of a moveable rack would require a space for the rack to move in equal to twice its length.

## CHAP. VI.

### *On the Dividing and Cutting Engine.*

Among the inventions in the art of Horology produced in this country, may be mentioned that of the wheel-dividing and cutting engines, which are said to have been invented by Dr Hooke. In the preface to the fourth edition of Derham's *Artificial Clockmaker*, he remarks, that "the invention of cutting engines, (which was Dr Hooke's,) fusee engines, and others, were never thought of till towards the end of King Charles the Second's reign." It is well enough known, that he contrived and used an endless screw and wheel for the purpose of dividing astronomical instruments, in 1664. The wheel-cutting engine was contrived by him in 1655; and, about the same period, he discovered that the barometer indicated changes in the atmosphere, and was connected with the weather. Ten years afterwards, he proposed a clock to register the rise and fall of the barometer, which was executed by Mr Cuming, in a clock made for his present Majesty. Sully carried over to Paris wheel-cutting engines, which were much admired there, not only for their beauty, and fanciful execution, but also for their utility. The French artists unwillingly admit our claim to this invention; and could they have brought forward documents to the contrary, it would most readily have been done. They maintain, that it could not have been invented and improved at the same time by any one man, an opinion in which we must agree with them. A wheel-cutting engine, and one which could divide almost any number, by means of an endless screw and toothed wheel, was made about 70 years ago by Hindley of York, which came afterwards into the possession of Mr Smeaton, from whom Mr Reid purchased it 30 years ago. As Hindley knew what had been done in this way by Dr Hooke, this seems to have been made in imitation of his, with some additions and improvements, as it is evidently not copied from that which is described in Thiout's work, vol. i. p. 53, Plate xxiii. fig. 1. said to have been invented by M. P. Fardoil, watchmaker at Paris. Ramsden's dividing engine, for which he got a considerable premium from the Board of Longitude, was executed on this principle, the great merit of which consisted in having a more perfect screw than had hitherto been made. See our article Graduation, for a copious history of *Dividing Engines*, and a full account of the engines invented by Ramsden and Troughton.

## CHAP. VII.

### *On Equation Clocks.*

The first equation clock, which is a very ingenious contrivance to shew both mean and apparent time, was made in London about 120 years ago. The following history of the invention is given by Berthoud in his *Histoire*.

"The most ancient equation clock," says he, "which has come to our knowledge, is that which was placed in the cabinet of Charles II. King of Spain, and which is mentioned at the end of *The Artificial Rule of Time*, by Sully, (edition 1717,) who gives the following account of it, from an extract of a letter of the Rev. Father Kresa, of the society of Jesus, written to Mr Williamson, watchmaker of the cabinet of his Imperial Majesty, of the 9th January 1715.

"What Mr Baron Leibnitz says, in his remarks at the end of Sully's book;—that if a watch or clock did of itself make the reduction of *equal time* to *apparent*, it would be a very fine and convenient thing;—on this subject I have to tell you, that from the years 1699 and 1700, there has been in the cabinet of King Charles II. of glorious memory, King of Spain, a clock with a royal pendulum, (a seconds' pendulum,) made to go with weights and not with springs, going four hundred days without requiring to be once wound up. I have, by order of his Majesty, and in his presence, seen and explained the instructions, which were sent from London with watches, which contained many curious things. I had orders to go every day to the palace during several months to observe the said clock, and compare it with the sun-dial. And at that time I remarked, that it shewed the equation of time *equal* and *apparent*, exactly according to the Tables of Flamstead,* which are found likewise in the Rodolphine Tables," &c.

* The earliest equation Tables were calculated by our first astronomer Royal, Mr Flamstead, at Greenwich.

Sully, at the end of the letter of which an extract has just been given, makes the following remarks, page 9:

"What the Rev. Father Kresa relates of the clock of the late King of Spain, is very true. It is more than twenty years since such clocks were made in London, and I believe that I am the first who applied this mechanism (for equation) to a pocket watch, twelve or fourteen years ago."

The following is a description of a very excellent and curious equation clock, which belonged to the late General Clerk. It was left, with several other things, to the late Sir John Clerk, and entailed on the house of Pennycuik.

The clock goes a month, strikes the hour, and has a strike silent piece. The 'scapement of it is made after that of John Harrison's, requiring no oil to the pallets; (see p. 476.) and the pendulum is a gridiron compensation one, composed of five rods, three of which are steel, the other two of zinc, or some compound of zinc. On the dial are seen the hours, minutes, and seconds, and their hands. The minute hand keeps mean or equal time; the equation of time is given by a hand with a figure of the sun on it, which makes a revolution every hour as the minute hand does, only for the most part it goes sometimes a very little slower, and sometimes a little faster than the minute hand, keeping solar or unequal time, and shews at all times when the sun is on the meridian. The age and phases of the moon are also represented, the days of the year and of the month, the degrees of the ecliptic, and the signs of the zodiac, the rising and setting of the sun, the length of the day, &c. The dial is a twelve inch arched one. Concentric with the arch is a sort of ring plate wheel of 365 teeth, making its revolution in a year, or 365 days. Its diameter is about 8 inches, and the breadth of the rim or ring 1½ inch nearly. On this ring plate, at the outermost circles containing divisions, are laid down the days of the year; and on the space next within, are the names of the months, the days being numbered by the figures 10, 20, 30, and so on. The next circles contain the 360 degrees of the ecliptic; the space within has the signs of the zodiac, and the numbers 10, 20, and 30, marked for the degrees in every sign, and corresponding with the days of the year and of the month when the sun is in any of these signs. The innermost circles contain what may be called the divisions of the semi-diurnal arcs. On the space outside of this, are marked the corresponding hour figures in Roman characters. This is what gives the time of the rising and setting of the sun, and the length of the day.

In the annual plate ring, are rivetted six small brass pillars, one inch and one tenth of an inch in height, whose opposite ends are screwed by steel screws, and their heads sunk into a plain ring wheel neatly crossed into six arms, the diameter being five inches and three quarters of an inch, and the breadth of the rim three-eighths of an inch. The back of this plain ring is distant from the back of the annual plate ring one inch and a quarter. The plain ring is at the centre, screwed on a brass socket, having a square hole in it. Within the frame of the clock movement, and at a perpendicular distance of six inches from the centre wheel holes, a steel arbor is run in, and at one end prolonged about an inch and a half beyond the fore frame plate, somewhat like a stud. The pivot in the fore plate is of such a length and thickness, as to allow a square on its outside. It is on this square that the equation elliptic plate is put, and above it is put on the annual plane ring by means of its socket, with a square hole in it. That part of the arbor which is above this socket is round, and serves as a stud for the moon's age ring socket, to revolve on it freely and easily. The moon's age ring turns within the annual plate ring, and is divided into 59 equal parts, numbered 3, 6, 9, and so on to 29½. Its diameter is five inches and one eighth; its breadth fully three-eighths of an inch, and it is connected with a plain wheel neatly crossed into six arms, of the same diameter and breadth of rim as the moon's age ring, having six small pillars, nearly an inch in height, rivetted into it, and the moon's age ring screwed at the opposite ends of three of them, by three sunk steel screws. This plain ring has a socket, which runs or turns on the stud, above the annual plain wheel; the face of the moon's age ring comes flush up with that of the annual plate ring, and both come up to the back of the dial, in which an opening in the arch is made, in order to shew a great part of what is on these rings. From the top of the arch, across the opening, and down in a straight direction, is stretched a very fine wire, serving as an index to the days of the year, the moon's age, &c. The annual plate ring and the moon's age ring move or turn from the right to the left hand, yet separately and independently of each other. On the inside shoulder of the socket of the moon's age ring is screwed a small bevelled wheel, having 37 teeth, and one inch in diameter, the use of which will be afterwards explained. In the dial is a circular opening of one inch and three quarters in diameter, a little below the opening in the arch; in this opening is exhibited the lunar globe of an inch and a quarter in diameter, made of brass and silvered; one half of it is perpendicularly painted black, in order to give the phases, the new and the full moon. On the arbor of the lunar globe are two wheels, one of 63 teeth, and about an inch in diameter, the other a bevelled one of the same diameter, and with 37 teeth. Both are placed below the lunar globe; the wheel of 37 and the globe are fast on the arbor, the wheel of 63 being keyed spring-tight above the bevelled one. The arbor of the lunar globe is in the plane of the dial or nearly so, and this bevelled wheel takes or pitches into that of the same number, which is screwed on the moon's age ring socket, as before mentioned; and by means of holes in the ring, the whole, that is, the globe, the bevelled wheels, and moon's age ring, &c. can be made to turn together, when the moon is at any time setting to its proper age. The pivots of the lunar globe arbor run on cocks which are screwed on to the back of the dial. Behind the globe, and at a little distance from it, is screwed on to the back of the dial, a sort of concave or hollow hemisphere of thin plate brass, painted inside of a sky blue colour.

We shall now proceed to shew how the moon's motion is produced. On the top of the month nut socket, where it lies in the plane of the dial, is cut a right handed double endless screw, working into a small brass wheel of 15 teeth, which is on the lower end of a long arbor, standing upright in a slit made in the dial. This slit is covered by a large circular silvered plate, on which are engraved the hours, minutes, and seconds; on the upper end of this long arbor is a pinion of 8, which carries about the wheel of 63, and with it, at the same time, the bevelled wheels, globe, and moon's age ring. The pivots of the long upright arbor run in small cocks attached to the back of the dial. The month nut, or hour wheel socket, makes a revolution in twelve hours, carrying the hour hand. The revolution of the moon's age ring is made in 29 days, 12 hours, and 45 minutes. The wheel of 63 and 15 being multiplied together, the product is 945, and this divided by 8, the number of the pinion, gives 118.125 times six hours, which being reduced gives the lunation, or a revolution of the moon's age ring as above, of 29 days, 12 hours, 45 minutes. The time of the revolution may be made out by another way. It is evident that one tooth of the small wheel of 15 is turned every six hours, of course the wheel will be made to have a revolution in 90 hours, and so will the pinion 8. Then if we say as 8 : 90 :: 63 : 708.75 hours, which is also equal to the given lunation of 29 days, 12 hours, 45 minutes. To produce the annual motion of the ring plate wheel of 365 teeth, the month nut is cut into 42 teeth, and makes its revolution, as was said before, in 12 hours, and turns a wheel of 84, concentric with which is a pinion of 8, leading a wheel of 96, having concentric with it a pinion of 12, leading the wheel of 365, which is the plate ring circle, having on it the days and months of the year, the degrees of the ecliptic, &c. turning once round in 365 days. Now as $365 \times 96 \times 84 = 2943360$, this product, divided by that of $42 \times 8 \times 12 = 4032$, will give 730 times twelve hours, or 365 days. The pinion of 12 is put on a square, which comes in and through a small hole in the large silvered circular plate; the wheel of 96 is put on a round part of the arbor, just below the pinion, and is keyed spring tight on it; by means of a small key which fits the square, to turn the pinion, the annual wheel of 365 teeth can be set to any required day of the month, which can be done without disturbing any of the motion-wheels. The setting of the moon's age ring is equally free as this is from any disturbing cause. The diameter of the month nut wheel of 42 is one inch, and three and a half tenths of an inch; that of the wheel of 84 is 2.5 inches, and near to a tenth and a half more. The wheel of 96 is three inches; its pinion of 12 is .307 of an inch, the pinion of 8 is .316 of an inch in diameter.

The minute pipe-wheel of 56 teeth, and 1.8 inch in diameter, runs on the arbor of the centre wheel, carrying the minute hand. It turns in the common way, the minute wheel *m* of the same number and diameter, whose centre lies nearly under that of the other, about .6 of an inch to the right of the middle line of the fore frame plate, and 1.7 inch from the centre of the minute hand wheel. The arbor of the minute wheel has a pinion of 8, leading in the common way the hour wheel of 96, whose diameter is 3.25 inches, that of the pinion is .426 of an inch. This pinion of 8 is put on the arbor, by means of a square, and with the minute wheel both are fast on the arbor. See Plate CCCIV. Fig. 7. The upper side of the wheel may be distant from the lower face of the pinion about .7 of an inch, the lower side having a proper freedom of the fore plate. Two wheels, one a plain wheel of 38, the other a bevelled one of 38, having the same diameter 1.2 inch, are screwed together, and on a socket common to both; the flat wheel is the uppermost, and is pretty close to the back of the bevelled one, whose teeth look downwards; their socket turns on the minute wheel pinion arbor, between the lower face of the pinion and the upper side of the minute wheel, having a proper end shake between them; the back of the flat wheel of 38 is below the lower face of the pinion .4 of an inch. These wheels of 38 can be made to turn on the minute pinion arbor, independent of it and the minute wheel. The minute wheel and pinion arbor extends a little way beyond and below the minute wheel, perhaps one inch and three or four tenths more to the end of its pivot; it extends also beyond the face of the pinion more than .6 of an inch to the end of its pivot, which runs into a cock C screwed on the fore frame plate. There is a part formed on the arbor of a flat circular shape, and whose thickness is rather more than that of the diameter of the arbor; in the middle of this is a hole tapped, into which is screwed a stud, standing at right angles to the arbor; a bevelled wheel of 38, and diameter 1.2 inch with its socket turns on this stud, which is placed on the arbor at that distance, so that the two bevelled wheels may fairly pitch into one another; the minute wheel is crossed into four, and through one of the cross's openings, the bevelled wheel B, which is on the stud, gets to pitch with the bevelled wheel *b* which is above the minute one. On the inside of the pillar plate is screwed a cock A, near 1.2 inch in height, and so that the middle part of the upper knee shall be opposite to the lower end and pivot of the minute pinion arbor. On one end of another arbor, in length about 2.1 inches, having a shoulder on it, is rivetted a bevelled wheel *c* of the same diameter and number of teeth as the others; another shoulder of just a sufficient thickness is made on this arbor at the back of the bevelled wheel; the rest of the arbor is nearly straight all the way, to the shoulder of a pivot which is at this end; from this shoulder the arbor is squared down for about .6 or .7 of an inch, to receive the socket of a small wheel W of 32 teeth, which turns behind the pillar plate; this wheel is nearly one inch in diameter, and a cock K is screwed on the back of the pillar plate, in which the pivot of the wheel of 32 runs; a pin is put through the socket and square, to keep the wheel fast to its place on the arbor. When the shoulder at the back of the bevelled wheel bears on the outside of the kneed cock, which is on the inside of the pillar plate, the cock having a hole in it which allows the arbor to go through and to turn in it, then the pivot of the arbor will run in the cock which is at the back of the pillar plate. The inside bottom of the bevelled wheel, which is rivetted on the shoulder of this arbor, has the end of the arbor made flush with it, and a hole made in the end and centre of the arbor to receive the lower pivot of the minute pinion, in which it runs or turns, the bevelled wheel which is on the stud being supposed to be set as low down as it shall meet and pitch properly with that which is at the end of the other arbor. It will now be seen that the end shake of these arbors, when combined, will lie between the minute pinion cock on the fore plate, and that which is on the back of the pillar plate. Let us suppose that the bevelled wheel, which is at the end of one of these arbors, remains as it were stationary, and that the minute pinion and wheel are carried about by the minute pipe wheel, which is on the arbor of the centre wheel; during a revolution of the minute wheel and pinion, the bevelled wheel, which turns on the stud, will be carried not only round with its stud, but is made to make another revolution by means of its turning round on the teeth of the bevelled wheel, which is stationary, causing the bevelled wheel, and the flat wheel connected with it, which are below the minute pinion, to make two revolutions in the hour; and as the flat wheel of 38 teeth turns the sun hand wheel of 76 teeth and 2.3 inches in diameter, this last must make its revolution in an hour. Its socket turns freely on that of the minute pipe wheel, which carries the minute hand; between the sun hand wheel and this minute pipe wheel is a slender spiral spring, the inner end of which is fixed to the lower end of the sun's wheel socket, the outer end being fixed in a stud on the upper surface of the minute hand wheel. This spring is for the purpose of keeping forward the sun hand to its place, notwithstanding any shake which may be among the teeth of those wheels concerned in the equation motion work. The sun's hand is of brass gilded, having the figure of the sun on it, at a little distance from the end which points to the minute divisions. The sun's hand lies between the hour and minute hands; the wheel of 76, which carries it, besides the motion of going once round in an hour, has at one time a small motion retrograde, at another a small motion progressive, according to the equation; and there are four times in the year when the minute and sun hands are nearly together. One half nearly of the sun wheel is crossed out, on that side in which the sun's hand lies, in order that the equilibrium of the hand and wheel may be as nice as possible, whatever may be the position of the sun hand.

From the centre wheel hole on the fore frame plate, towards the left hand, and a little upwards, take, with a pair of compasses, a distance of 3.8 inches, and sweep an arch; and then from the centre of the hole, in which the arbor runs, which carries the annual plate wheel, take in the compasses an extent of 4.6 inches, and sweep another arch so as to intersect the first, the place of intersection will be that of an arbor having pivots, one of which runs into a cock, screwed on the back of the pillar plate; the other runs into a cock screwed on the front of the fore frame plate; a notch is made on the edge of each frame plate to admit the arbor to come into its place. On the end of this arbor, which is just behind the pillar plate, is fixed a rack or segment of a circle 5 inches radius, having 32 teeth cut on it, and cut from a number on the engine plate of 318; the rack-teeth pitches into the small wheel of 32, which lies behind the pillar plate, and whose centre coincides with that of the minute pinion arbor, as mentioned before. On the other end of this arbor, and beyond the fore frame plate a very little, is fixed an arm of 4.5 inches long, having at the end of it a smooth hard steel pin, which bears on the edge of the annual elliptic equation plate, being made to do so by means of a coil or two of watch main spring, not very strong, attached to the arbor, near to the inside of the fore frame plate, the outer end being fixed to one of the pillars, or to a stud fixed for that purpose on the inside of the fore plate. The elliptic equation plate is a very irregular sort of a figure, as may be conceived in some degree by the description of its shape; its greatest length over all is 6.5 inches; the centre is 3.8 inches from the broadest end, and 2.7 inches from the narrowest; the nearest edge across the centre is about one inch, and the edge opposite is 1.8 inch; the greatest breadth of the broad end is near to 4 inches, that of the narrowest end is 2.8 inches. During the course of its annual revolution, the edge of the elliptic plate makes the arm which has the steel pin in it rise to various heights, and fall as variously to different depths. By this rising and falling, the rack which is at the opposite end of the arbor, is made to have a motion sometimes backward, and at other times forward, which it communicates to the small wheel of 32, behind the pillar plate, and of course to the bevelled wheel of 38, on the same arbor with it. This continually causes a small change of place to the bevelled wheel of 38, consequently a change of place to that which turns on the stud, and hence to the wheel carrying the sun hand; this change is what gives the equation shewn by the difference of time between the minute and sun hands. When the pin in the arm falls, the equation or sun hand goes forward, and when rising it goes backward. The greatest negative equation for 1815, on the 3d day of November, is 16 minutes, 14.9 seconds, which, added to the greatest positive equation for the same year on the 11th of February, is 14 minutes, 36.5 seconds, making in all 30 minutes, 51.4 seconds; so that one tooth of the wheel of 32 may be nearly equivalent to one minute of equation. To trace properly a true figure to the equation plate must be a very tedious and nice operation; for this purpose the rack, and all the wheels immediately connected with the equation, must be put into their places, as also all those which give motion to the annual plate, and to have a spring tight arm, having a sharp point to it, bearing on the face of the brass plate which is to be the elliptic one: the sharp point must lie so as to coincide with the side of the steel pin, when bearing on the edge of the elliptic plate. The sun and minute hands being on, and the annual plate set to the 1st of January, the equation hand set to the equation for that day, then by setting forward the minute hand until 12 or 24 hours have elapsed, the equation hand may be changed to what it ought to be, in the same time; so by going on step by step in this way, the figure of the equation plate may be truly done. The rack must be artificially made to assist in this; and when the revolution is completely at the end, before taking out the rack and the equation wheels, marks must be made to one of those teeth, which must be marked by its corresponding space in the other wheels, so that when they are again put into their places, they shall give such equation as was done when tracing for the elliptic plate.

Besides the days of the month, which are shewn on the annual plate, there is a common month ring, having 31 figures engraved on it, placed as usual at the back of the dial. One of these figures is shifted every day through the whole ring when the month consists of 31 days; and two figures at the last are shifted at once when the month consists of 30 days, to bring the ring to the first day of the succeeding month; and at the 28th of February four figures are shifted, so as to bring the ring to the 1st of March: by this means the day of the month ring requires no shifting or correcting at these periods, as those in the common way do. To produce this motion, five short steel pins are placed in a circle, on the under side of the elliptic plate, whose radius may be about half an inch, and set at such a distance from one another as to correspond with the number of days between February and April, between April and June, between June and September, between September and November, and between November and February. This may be done by applying the elliptic plate on a cutting or dividing engine, having the number 365 on the dividing plate. When fixed on the engine, and set to the first point of the number, make a point for February on the elliptic plate; then count off 61 from the dividing plate, which will give the place for the pin on the 30th of April; another 61 will bring it to June 30th; 92 will give the 30th of September; 61 the 30th of November; and 90 more will bring it to the 28th of February, the point which was set out from. When the pins are put in the elliptic plate, that for February will require to be longer than the others, for a reason which will be explained when we come to shew the use of these pins. The month-wheel of 84 teeth, and whose diameter is 2.75 inches, has its centre on the left hand side, distant from the central perpendicular line 1.4 inch, and from the centre hole in the fore frame plate 2 inches. The month wheel, as usual, is turned about by the month nut. A long piece of brass forming two arms, each four inches in length, has a small arbor through the middle of the whole length of eight inches. The pivots of this arbor run into small cocks, attached to the front of the fore plate, keeping the long piece of brass very near to the plate; indeed a great part, particularly the end of the upper arm, and towards it, is sunk partly into the fore plate. This long piece of brass is placed so that one of the arms shall come to the socket of the month wheel, and the other, with its end nearly below the circle in which are the five pins, in the annual elliptic plate described as before. A spring is placed below this upper arm to keep it up, unless when any of the pins get on the end of the arm and press it down. The end of the arm is chamfered, or made so that any pin, when approaching it, gets easily on, and presses it down gradually, by means of ascending the chamfered part as it were; and when past this, it meets with a flat and very narrow place, where it cannot remain longer than some time short of 24 hours, say 16 or 18 hours, or perhaps not so long. After having passed the flat part, it meets with a chamfered side opposite to that of the first. Besides that of freeing the pin, this is made for the purpose of more easily setting back or forward the annual plate.

The month wheel has its socket equally long on both sides, and quite straight; the length of each may be .6 or .7 of an inch. Two small brass pillars are rivetted on the upper side, and opposite one another, each at a distance from the centre of the wheel about .7 of an inch, (see Plate CCCIV. Figs. 8, 9.) the height of the pillars from the wheel to the shoulder about half an inch; and from the shoulder of each pillar a sort of straight pivot is prolonged, about one half inch more; the diameter of these pivots about one-tenth of an inch; that of the pillar .2 of an inch. There is another socket which goes easily on the lower or under socket of the month wheel, which is rivetted in a rectangular piece of brass, about an inch long, and half an inch broad, or nearly so, say .4 of an inch. In this piece of brass, on the side opposite that of the socket, are also rivetted two small and straight brass pillars, about an inch in length, and the diameter about one-tenth of an inch. There are holes in the month wheel, to allow these pillars to go easily back and forward in them; their places will be equally between the month wheel socket, and the pillars which are rivetted in the month wheel. The other ends of the small straight pillars are made fast, by two small steel screws, to a piece of brass, which is formed to correspond with two broad crosses of the month wheel. Only one of them is made to have at the end a segment of a circle, whose radius is nearly equal to that of the month wheel. On this segment three teeth are cut, equal in their spaces and form to those of the month ring. In the arms or crosses of the segment are three holes, one of which goes easily over or on the upper socket of the month wheel; the other two holes go easily on the small straight pivots which have been already mentioned. This segment cannot be put on the ends of the small pillars, till the socket of the rectangular piece of brass is put on the lower socket of the month wheel, having previously made the pillars connected with it to pass through their holes in the month wheel. It will be easy to perceive, that when the segment is put on to its pillars, and a sufficient space left behind the month wheel and the rectangular piece of brass, its socket may be made to pump up and down on that of the month wheel, and at the same time carrying the segment back and forward with it; a pin in the month wheel stud keeps the month wheel socket always to its proper end shake, notwithstanding any motion of the segment backwards and forwards. Below the rectangular piece on its socket, a small groove is turned out of it, for the purpose of a forked piece getting in on it; this forked piece is formed on that end of the arm which lies along the fore plate, and on to the socket or centre of the mouth wheel.

From the preceding description it is evident, that when any of the elliptic plate pins come to press down that end of the long arm which lies near and under them, the forked end will raise up the grooved socket, and the segment which is connected with it; hence the teeth of the segment will meet with pins which are at the back of the month ring, and by their means will turn the month ring. On the month wheel is fixed a pin, which, in common, shifts the day of the month ring; but in those months in which there are only 30 days, the pins in the elliptic plate, which press down the end of the arm, make the segment be pumped up only so far as to meet with one of the pins at the back of the month ring, which is a little longer than the other two; and one day being shifted by it, and another by the fixed pin in the month wheel, this makes the shifting from the 30th to the 1st day of the succeeding month. The pin in the elliptic plate for the month of February being longer than the others presses the end of the arm a little more down, consequently the pumping up of the segment must be to a greater height; by this means the three teeth on the segment get hold of the three pins on the back of the month ring; this, with the fixed pin in the month wheel, are ready to shift four teeth of the month ring, viz. from the 28th of February to the 1st of March; and, by this very ingenious sort of mechanism, the month ring shows always the right day of the month, except on the 29th of February in leap-years. It may be necessary to notice, that the fixed pin in the day of the month wheel must be placed at such a distance from the first tooth on the segment, as is equal to the space between the teeth on the segment. The month ring is not attached by rollers to the back of the dial in the usual way, but runs in four rollers, which are fixed on four brass studs on the fore frame plate. This is for the conveniency of seeing more easily the operations of the segment with the month ring, when the segment is pumped up and down.

The construction of the month wheel, and of the apparatus for shifting the month ring, will be better understood from Figs. 8 and 9, where AA is the month wheel; B, B, two arms or crosses nearly similar to those of the month wheel, having a hole in the centre which goes freely on the upper socket of the month wheel; on one of these arms is a segment of a circle, nearly of the same radius as that of the month wheel, having three teeth cut on it, like those of the month ring; *a*, *a*, are two brass pillars rivetted on the upper side of the month wheel, the upper ends being formed into a sort of pivots; on these and the month wheel socket, the segment is made to move freely up and down. C is a rectangular piece of brass, into which a socket is rivetted, which moves up and down on the lower socket of the month wheel, having a groove turned out on it, which receives the forked end of the arm, which pumps it up and down; *b*, *b*, are two small brass pillars, which are rivetted also into the rectangular piece of brass, having two holes in the month wheel, through which they pass easily up and down; the other ends of them go into the segment at *b*, *b*, and are screwed to it by means of two small screws. On one of the arms of the month wheel is screwed a small kneed sort of cock *d*, having a pin fixed in it, for turning the day of the month ring in the usual manner.

## CHAP. VIII.

### *On Repeating Clocks and Watches.*

To those who do not sleep well, nothing can be more convenient and useful than a repeater, whether it is in a watch, or in a small fixed clock. A history of this invention is given by Mr Derham in his *Artificial Clockmaker*. Berthoud, in his *Histoire*, has given the following account of it, which is taken chiefly from Derham.

"The art of measuring time, (says Berthoud,) was again enriched with two fine and useful inventions before the end of the seventeenth century. One was the equation clock; the other, which is the most precious, and of the most general utility, is that kind of striking which has been called repeating. It is of the most ingenious mechanism, and when added to a clock, serves to make known at pleasure, at every instant of the day or night, without seeing the dial, the hour and the parts of the hour, which are pointed out by the hands of the clock. Both these inventions are due to the English artists."

"The clocks in question here, (says Derham,) are those which, by means of a cord, when pulled, strike the hours, the quarters, and even some the minutes, at all times of the day and of the night. This striking or repeating was invented by a Mr Barlow, towards the end of the reign of King Charles II. in 1676."

It is not mentioned by Derham, whether Barlow was a watchmaker or not. We have heard it said by old watchmakers, that he was a clergyman. This seems in some measure confirmed, by his having applied to Tompion to make his repeating watch, when he was about to obtain a patent for the invention.

"This ingenious invention," continues Berthoud, "which had not been before thought of, made at the outset a great noise, and much engaged the attention of the London watchmakers. On the idea alone which each formed of it, they all set to work to try the same thing, but by very different ways; whence has arisen that great variety in the work of repeating motions, which was seen at this time in London.

"This discovery continued to be practised in chamber clocks until the reign of James II. It was then applied to pocket watches. But there arose disputes concerning the author of the invention, of which I shall simply relate the facts to the reader, leaving him to judge of it as he thinks proper."

Towards the end of the reign of James II. Mr Barlow applied his invention to pocket watches, and employed the celebrated Tompion to make a watch of this kind according to his ideas; and at that time, conjointly with the Lord Allebone, chief justice, and some others, he endeavoured to obtain a patent for it.

Mr Quare, an eminent watchmaker in London, had entertained the same notion some years before, but not having brought it to perfection, he thought no more of it until the noise excited by Mr Barlow's patent awakened in him his former ideas. He set to work, and finished his mechanism. The fame of it spread abroad among the watchmakers, who solicited him to oppose Barlow's privilege to obtain a patent. They addressed themselves to the court; and a watch of the invention of each was brought before the king and his council. The king, after having made trial of them, gave the preference to that of Mr Quare.

The difference between these two inventions is this:—The repetition in Mr Barlow's watch was effected by pushing in two small pieces, one on each side of the watch case, one of which repeated the hour, the other the quarters. Quare's watch repeated by means of one pin only fixed in the pendant of the case, which, being pushed in, made the repetition of the hours and quarters, the same as is done at this present time, by pushing in once only the *pendant* which carries this pin.

This invention of repeating the hours in small fixed clocks, and in watches, was soon known and imitated in France; and these machines were very common in 1728, when the celebrated Julien Le Roy was much occupied in their improvement. It was at this period that he made the repeating clock, of which a description is given at the end of *The Artificial Rule of Time*. This was made for the bedchamber of Louis the Fifteenth of France.

The first repeaters, even those of Quare's, as well as others, gave the number of the hour according to the length pushed in of the pendant; which was very inconvenient, by striking any hour, whether the pendant was pushed home to the snail or not. This frequently caused mistakes, in regard to the true hour which ought to have been given. From the report of our predecessor, Mr James Cowan of this place, who went to Paris in 1751 for improvement in his profession, and who executed some pieces under Julien Le Roy, it was *he* who introduced the mechanism into repeaters, which prevented the watch from striking any thing but the true hour. This, we think, was done to the repeating clock for Louis the Fifteenth's bedchamber. In this construction, unless the cord or pendant made the rack go fully home to the snail, it either struck none, or struck the true hour, which was a very considerable improvement. The piece employed for this purpose is called the *all or nothing* piece. Considering the great talents which Julien Le Roy possessed, we have no reason to doubt of this improvement being his.

"Although the *repetition*," says Berthoud, "such as is now in practice, is a particular kind of striking, its mechanism differs totally from that of the striking clock; 1st, Because every time that it is made to repeat, the main repeating spring is wound up; whereas, in the common striking part, the main-spring is wound up only once in eight days, fifteen, or a month: 2d, In the repetition we must substitute for the count-wheel, which determines the number of blows that the hammer must strike, a contrivance wholly different. The first author of this ingenious mechanism substituted for the count-wheel a piece, to which, in regard to its form, he gave the name of the *snail*. The snail is a plain piece, divided into twelve parts, which form steps, and come gradually in from the circumference towards the centre. It makes a revolution in twelve hours. Each of the steps is formed by a portion of a circle. Every time that the clock is made to repeat the hour, the pully which carries the cord is connected with and turns a pinion, which leads a rack, whose arm falls on one or other of the steps of the snail, (on the cord being pulled,) and regulates the number of blows which the hammer ought to give; and as this snail advances only one step in an hour, it follows, that if it is wanted to be made to repeat at every instant in the hour, we should have always the same number of blows of the hammer; whereas, in setting off the wheel-work of an ordinary striking movement more than once in the hour, we should have a different hour. A count-wheel would then not be fit for a repetition. The mechanism of the repetition has a second snail, which bears four steps also in portions of a circle, to regulate the blows which the quarter hammers must give."

The count and hoop wheels, and locking plate of the old striking clocks, for regulating the number of blows of the hammer, and locking the wheel-work, was excellently contrived. It had only one inconvenience, for when set off by accident, it would prematurely strike the hour to come: this made it requisite to strike eleven hours before it could be again brought to the hour wanted. Had it not been for the invention of the repeater, these would have continued, and would have been still made in the modern clocks, the same as in the ancient ones. But the snail of the repeater shewed that it could be adapted for regulating the number of blows for the hammer of a common striking clock, and has prevented the inconvenience of striking over a number of hours, before the clock could be set to the right hour of striking.

"We owe to Julien Le Roy," continues Berthoud, "the suppressing of the bell in repeating watches, a change which has made these machines more simple, by rendering the movement larger, more solid, and less exposed to dust. These watches, which he called *raised brass edges*, are of a more handsome form. From the time of this celebrated artist, all the French repeaters have been made according to this model; but in England, where repeating watches were invented, they make them for the most part with a bell; and in Spain, this construction is still more preferred. In repeating watches without a bell, the hammers strike on brass pieces, either soldered or screwed to the case. Repeating watches with a bell have, also, as those without one, the property of being *dumb*, that is to say, of being able to make it repeat at pleasure, without the hammers being allowed to strike on the bell, or brass pieces."

This effect is produced after the pendant is pushed in, by putting the point of the fore-finger on a small spring button, that comes through the case. Being a little pressed in, it opposes a piece against the hammers, which prevents them from striking either a bell or the brass pieces inside of the case; by which means the blows for hours and quarters are *felt*, though they cannot now be easily heard. This makes this kind of repeaters very convenient for those who are deaf, as during the dark of night they can feel the hour at a time when they cannot *see* it. These *sourdine* or dumb parts have been left off of late years; yet they are not without their advantages, as has been now shewn.

The late Julien Le Roy had tried to render repeating watches more simple, by suppressing the wheel-work which serves to regulate the intervals between the blows of the hammers, and also the main repeating spring. This celebrated artist succeeded in these, to construct new repeating movements, of which several have been made. But it appears that the public have not found them very convenient, so that this mode of composing them has not been imitated.

The only one of this kind which we have seen of Julien Le Roy's, was a very good one in the possession of John Rutherfurd, Esq. of Edgerston. Although they have not been copied, they certainly deserve to be so.

Repeaters have of late been made with springs in place of bells, which are a very ingenious substitute, it must be allowed, of Swiss invention, though they are as superfluous as bells. Considerable trouble is necessary in making and placing them. They ought never to be recommended, if it could be avoided; but we are often obliged to yield to the fashion of the day, even when it does not coincide with our own opinion. When three or more hammers are used to give the quarters, we then would admit springs in place of bells, as when they are well tuned, they give a most beautiful chime for the quarters: were bells introduced for this purpose, they would give a clumsy appearance to the watch. Julien Le Roy saw good reasons for setting aside the bell; and no plan of a repeater will ever be superior or equal to that of his, which Graham frequently adopted in many of his watches, though his repeating motions were different; Julien Le Roy's having what is called the plain, and Graham's the *Stogden* motion, a most ingenious contrivance, requiring great judgment to plan, and nice execution in making it. This motion is well adapted for half quarters: Though we have hardly seen a French repeater with it, yet it is not unknown to the foreign artists, as appears from Thiout's work, tom. ii. p. 367, plate xxxvi. fig. 3. Paris, 1741. This repeating motion must have got its name from the inventor. Upon inquiring after him when in London, in the year 1770, we learned, with much regret, that he had died a few months before in a charity workhouse, at a very great age. The name appears to be German; but whether he was a foreigner or an Englishman, we have not been able to learn.

We shall now lay before our readers a complete description of the repeating movement and motion-work of clocks and watches, which we have taken principally from Berthoud's *Essai sur l'Horlogerie*

Clocks that have a striking part, strike of themselves the hours, and some strike the hours and half hours; but those having a repeating part strike only on a cord being pulled, if it is a clock; and if it is a watch, when the pendant or pusher is forced home; thus two hammers strike the hour and the quarters, which the hands point to on the dial. We shall see, by the description of a repeating clock, how this is produced; but before doing so, we shall give a general idea of this ingenious mechanism, which is nearly the same for a clock as for a watch.

In order to make a clock repeat the hour, (see Plate CCCV. Fig. 2.) the cord X is drawn, which is wound round the pully P, fixed on the arbor of the first wheel of a particular wheel work, the sole object of which is to regulate the intervals between each blow of the hammer. The arbor of this wheel has on it a hook, which takes hold of the inner end of the repeating main-spring contained in the barrel B, Fig. 3. On this arbor is also a plain wheel G, Fig. 1. having fifteen pins in it which serve to raise the hammers, twelve of them for the hours, and three for the quarters. The number of blows that the hour hammer strikes, depends on the greater or less course which the pin wheel G is made to take when pulling the cord, and this course depends itself on the hour pointed at by the hands on the dial. Thus, if the cord is drawn when it is twelve hours and three quarters, the pin wheel is obliged to make an entire revolution; at this instant the repeating spring brings it back, in which course it makes the hammer give twelve blows for the hours, and then three for the quarters. To distinguish the quarters from the hours, a second hammer is added, which, with the first, makes a double blow at each quarter.

It must now be shown by what means the course which the pin wheel takes is regulated on the cord being pulled, and how it is proportioned to the hour which the hands point to on the dial.

A wheel S, or minute wheel, of the dial work, Fig. 3. has its arbor prolonged, and outside of the back of the pillar plate. (In this case, and in common, the repeating work is put between the dial and foreplate of the frame.*) It carries the piece *sh*, Fig. 2. the pin of which *c* turns the star wheel E, which takes twelve hours to go once round, and carries with it a piece L, called the *hour snail*, divided into twelve parts tending to the centre of the star wheel. Each of these parts forms different depths, like as many steps, which gradually come nearer the centre, and which serve to regulate the number of the hours which the hammer must strike. For this purpose the pulley P carries a pinion *a*, which pitches in with a portion of a wheel C, Fig. 2. called the *rack*. When the cord is pulled, and the rack is in consequence made to advance towards the snail, the arm *b* stops on such a step of the snail as it may meet with in its course; and, according to the depth of this step, the hammer strikes a greater or less number of blows. It will strike only one hour if the arm *b* of the rack is stopped on the step 1, the most distant one from the centre, as then the pin wheel getting only one of its pins engaged, the hammer strikes only one blow. If, on the contrary, the step 12, which is the deepest and nearest the centre, is met by the arm *b* in its course, which cannot get there until the pin wheel shall have made one turn, then the spring in the barrel bringing it back, will cause the hammer to give 12 blows.

It remains to be seen how the quarters are repeated. The piece *s*, Plate CCCV. Fig. 2. which turns the star wheel, and takes one hour to make a revolution, is carried by another snail *h* (called the *quarter snail*,) formed by four divisions, making three paths or steps, on one of which, when the cord is pulled, the arm Q of a piece QD, called the *finger*, places itself, and according as the step is nearer or farther from the centre of the snail, the end D of the finger finds itself more or less aside from the centre *a* of the pulley P; so that when the pull of the cord is finished, and the pulley returns by the force of the spring in the barrel, one of its four pins acts on this finger, namely, the one which it finds at a distance from the centre *a*, which answers to the elevation of the arm D, and this is what determines the blows for the quarters: thus when the finger is applied on the pin nearest the centre of the pulley, the

* This part of the repeating work, with the dial wheels, go under the general name of the *motion work*.

hour hammer strikes only the number of hours that the snail L and the arm *b* of the rack have determined. If the finger is placed on the second pin, it does not stop the pulley till after the hour hammer has struck the hour, then a quarter, and so on for the three quarters. Having thus given an idea of the essential parts of a repeater, let us now proceed to a particular description of a complete repeating clock with an anchor 'scapement.

Plate CCCV. Figs. 1, 2, and 3. represent all the parts of a repeating clock, seen in plan. Fig. 1. represents the wheel and pieces contained within the frame, or what are put between the two plates, with the exception of the anchor A, which is placed in this way, to show the 'scapement.

The wheels B, C, D, E, F, are those of the movement. B is the barrel, which contains the clock main-spring. The great wheel is fixed to the bottom of the barrel B, and pitches into the pinion of the wheel C, which is the great intermediate wheel. D is the third, or the centre or minute wheel.* E the fourth wheel, or that where the contrate wheel was usually placed. F the ratchet, or 'scapement wheel. The centre wheel D makes a revolution in an hour. The pinion on which this wheel is fixed has its pivot prolonged, which passes through the fore plate, Fig. 3. This arbor or pivot, Fig. 4. enters spring tight into the cannon of the minute pipe wheel *m*, seen in perspective, Fig. 5. which makes also, by this means, a turn in an hour. This cannon carries the minute hand; and its wheel *m* pitches into the returning or minute wheel S, of the same number of teeth, and of the same diameter as the wheel *m*. The pinion of the wheel S makes twelve revolutions in the time that the hour wheel C makes one. The wheel C, which is one of the dial wheels, takes then 12 hours to make one revolution, and is that which carries the hour hand.

It must be observed, with regard to these three wheels, C, *m*, S, which are called dial wheels, that they are always the same, whether the clock is a striking one or a repeating one; their effect being, to cause the hour or dial wheel C to make a revolution in the space of twelve hours. The wheels G, L, M, N, Fig. 1. and the fly V, form the wheel work of the repeating part. The object of this wheel work, as has already been mentioned, is to regulate the interval between each blow of the hammer. The ratchet R, and the pin wheel G, are fixed on the same arbor in common with the wheel L, within whose centre it freely turns. The spring *r*, and the click *c*, are all placed on the wheel L.

When the cord X, which is wound round the pulley P, Fig. 2. is pulled, the ratchet R, Fig. 2. fixed on the same arbor as the pulley, retrogrades, or goes backwards, and the inclined planes of the teeth raise the end of the click at O. Then the repeating spring brings back the ratchet, whose teeth butt or stop against the end of the click, which carries about the wheel L, and the wheel work M, N, V: but while the ratchet R thus carries the wheel L, and while the pin wheel G, and the pulley P of Fig. 2. which are fixed on the same arbor, turn also, the pins of the wheel G act on the pieces *m*, *n*, Fig. 1. whose arbors prolonged carry the hammers *l*, *m*, Fig. 2. Each piece *m*, *n*, is pressed by a spring, to bring forward the hammers, after the pins had made them rise up or go backward. The spring *r* is only seen, which acts on the piece *m*; that which acts on the piece *n* is placed under the plate which carries the motion work, Fig. 2. The piece *o* serves to communicate the motion of that of *m* to the arbor or piece *n*, which carries the hour hammer.

The piece, (*bascule*,) or see-saw *m x*, Fig. 1. is moveable on the arbor which carries the quarter hammer. On this arbor below *m x*, an arm like that of *m* moves, on which act the three pins placed on the under side of the wheel G. These three pins serve to raise the quarter hammer fixed on the arbor which carries the piece *m*. It is this hammer which the spring *r* presses. When the cord is pulled, the wheel G is made to go backward, the pins of which come to act on the back part of the arm *m*, which yields, and comes from *m* to *x*. The small arm which is below for the quarters makes the same motion; and when the repeating spring brings back the wheel G, a small spring, which acts on these pieces *m*, obliges them to get engaged between the spaces of the pins, and to present the right planes on which these pins act to raise the hammers.

The pulley P, Fig. 2. carries the pinion *a*, which pitches into the rack *b* C, the effect of which is, as has been said, to make the point *b* go upon the steps of the snail L, and determine the number of blows which the hour hammer must give.

The star wheel E, and the snail L, are fixed together by two screws. This star moves on a screw stud V, Fig. 2. attached to the piece TR, moveable itself in T. This piece forms, with the plate, a small frame, in which the star E and snail L turn. One of the radii or teeth of the star bears on the jumper Y, which is pressed by the spring *g*. When the pin *c* of the quarter snail turns the star wheel, the jumper Y moves out, receding from V to the centre of the star, until the tooth of the star arrives at the angle of the jumper, which happens when it has made half of the way which it ought to do. Having escaped this angle, the inclined plane of the jumper pushes it as it were behind, and makes it precipitately finish the other half; so that from the changing of one hour to another, that of the star and of the snail is done in an instant, which is when the minute hand points to the 60th minute on the dial.

The jumper finishing thus in turning the star, each tooth placed in *c* comes on the back of the pin *c*, and makes the *surprise s*, to which it is fixed, advance. The surprise is a thin plate, adjusted on the quarter snail; it turns with it by means of the pin which comes through an opening made in the surprise; the advance which the star wheel teeth causes the surprise to make, serves to prevent the arm Q of the finger from falling into the step 3, which would make the three quarters be repeated when at the 60th minute. As soon as the star changes the hour, it then obliges the *surprise* to advance to receive the arm Q; so that if the cord is pulled at this instant, the hammer will strike the precise hour.

The arm Q and the finger are moveable on the same centre. When we have drawn the cord, and when the pins of the pulley have freed or left the finger at liberty, then the spring *p* makes the arm Q fall on the quarter snail, and the finger D presents itself to one or the other of the pins in the pulley. These two pieces can turn one on the other, and be moved separately: This serves in the case where the arm Q going to fall on the step *h* of the quarter snail, and the finger D being engaged in the pins of the pulley, this arm bends and yields to the pins of the pulley, which at this instant cause it to retrograde or go backward; it is necessary that the pin for the present in

* Our workmen give the name of minute wheel to what Berthoud gives the name of the returning wheel; and what he calls the minute wheel, obliges us to make it the centre or third wheel, in conformity to their language.

hold can make the finger move separately from the piece Q. The spring B brings back the finger D, as soon as the pin has retrograded, so that it may present itself to the pin which stops for the hour alone, or for the quarter, if the arm falls on the step 1, &c.

Having seen the most essential parts of the repetition, there remains only one of which an idea must be given, and which we shall endeavour to make the reader understand. This is the *all or nothing*, which has this property, that if the cord is not fully drawn, so as to make the arm *b* of the rack C press on the snail L, the hammer will not strike; so that, by this ingenious mechanism, the piece will repeat the exact hour; if otherwise, it will not repeat at all.

We have seen, that when the cord X is pulled, the pin wheel G, (Fig. 1.), oversets the piece *m*, and makes it come to *x*; and that before the hammer can strike, a small spring must bring back the piece *m*, to put it in holding with the pins; after that, it is easy to see, that if, in place of allowing the piece *m* to take its situation, it were made to be still more overset, the repeating spring bringing back the pin wheel, the hammer would not strike while this piece remained overset; this is precisely the effect that the piece TR (Fig. 2.) produces, which is on that account called the *all or nothing* piece. This is effected in the following manner: The piece *m* (Fig. 1.) carries a pin, which goes through the plate by the opening *o*, (Fig. 2.); if we pull the cord, the pin wheel causes the piece *m* to move, as we have just now seen. The pin which it carries comes to press against the end *o* of the all or nothing piece, and sets it aside, so that the pin shall arrive at the extremity, which is a little inclined: But the spring *d* tending to bring back the arm *o*, the inclined plane obliges the pin to describe still a small space, which takes the arm *m* (Plate CCCV. Fig. 1.) entirely out of the reach of the pins, so that the hammer cannot strike, unless he pin is disengaged from the end of the arm *o*. To effect this, the arm of the rack must come and press on the snail L, which moves on a stud V, fixed to the all or nothing piece TR. Now, in pressing the snail, the arm *o* of the pin is set aside, which getting free, gives liberty to the arm *m* to present itself to the pins of the wheel G, and to the hammers that of striking the hours and quarters given by the dial work and hands.

The ratchet R (Fig. 3.) is that of the click and ratchet work of the movement; *c* is the click, *r* the spring. The ratchet R is put on a square of the barrel arbor; this square being prolonged, serves to wind up the spring by means of a key; B is the barrel in which the spring or motive force for the repetition must be put; V is a screw, called the eccentric or pivot carrying piece: On the part which enters with force into the plate, a little out from the centre of the arbor of the screw, a hole is made for the pivot of the anchor A. In making this screw turn, the pivot of the arbor of the anchor is made to go farther or nearer the centre, and consequently the anchor itself, so that the points of the pallets take more or less in, according as is required with the teeth of the 'scapement wheel. A, Fig. 2. is the cock of the 'scapement, it carries the silk thread or spring, to which the pendulum is suspended. One of the ends of the silk thread is attached to the arbor *c*, which is called *avance* or *retard*, (fast or slow); the other end of this arbor goes through to the dial, and is squared, to receive a small key. By this means, we can turn the arbor *c* to any side, so as to lengthen or shorten the silk thread which serves to suspend the pendulum, whose length is changed by this method.

The anchor A, Fig. 1, is fixed on an arbor similar to that for a second's pendulum. This arbor carries the fork T, which gives motion to the pendulum. The pivot which this arbor carries at the end where the fork is, enters into a hole made in the cock A, Fig. 2.

Fig. 4. represents in perspective the wheel D, whose revolution is performed in an hour; it is the arbor of it that carries the wheel *m* of Fig. 3. This wheel *m* is seen in perspective in Fig. 5. whose cannon serves to carry the minute hand. Fig. 6. represents in perspective the wheel S of Fig. 3. It is the arbor of this wheel prolonged, which passing to the motion work, carries the quarter snail *h*, Fig. 2. The pinion of this wheel S, pitches into the hour wheel, seen in perspective in Fig. 7; and it is on the socket of this wheel, that the hour hand is adjusted or fixed.

It will be seen from the preceding description, that the pieces of the repeating motion work are here placed on the back of the pillar plate. Placing them on the fore plate will make no difference.

We shall now proceed to describe a repeating watch with a horizontal or cylindrical 'scapement of Graham's.

What has been said concerning the repetitions in pendulum clocks, and the simple or plain watch, being once well understood, the reader will have no difficulty in comprehending the mechanism of a repeating watch, which is only on a small scale what the clock is on a great scale.

Fig. 1. of Plate CCCVI. represents the wheel-work of the movement and of the repetition, and all the pieces which are put within the frame-plates. There is a distinction here between the wheels,—those of the movement, or which serve to measure the time, as the wheels B, C, D, E, F, and those of the repetition, which serve to regulate the interval between the blows of the hammer: such are the wheels *a, b, c, d, e, f*, whose assemblage is called the little wheel work or runners.

The spring of the movement is contained in the barrel A; B is the great or fusee wheel; C the centre or second wheel, whose arbor prolonged carries the cannon pinion on which the minute hand is fitted and adjusted; D is the third wheel; E the fourth wheel; and F the cylinder, 'scapement, or balance wheel. The fusee I is adjusted on the great wheel B, a spring-tight collet and pin keeping the wheel to its place on the fusee; the chain is wound round on the fusee, and holds likewise of the barrel. The hook O of the fusee serves to stop the hand, on the watch being full wound up, by the hook stopping against the end of the guard de gut stop (the name it got before the chain was put to the fusee; the modern name of it is the fusee stop,) C (Fig. 2.) attached to the other plate; its effect is the same as in the plain watch. Fig. 3. of Plate CCCII. represents the cylinder 'scapement, of which a description has already been given in p. 484.

B is the balance fixed on the cylinder; F is the cylinder wheel, which is represented as tending to act on the cylinder, and cause vibrations to be made by the balance. None of the pieces are drawn here, such as the cock, slide, curb, and pendulum or spiral spring, as they would have rather made the 'scapement part obscure. The wheel work, or runners of the repetition, is composed of five wheels, *a, b, c, d, e*, and of the pinion *f*, and of four other pinions. The effect of this wheel work is to regulate the interval between each blow of the hammer; so that if the first wheel *a* is made to have 42 teeth, the second *b* 36, the third *c* 33, the fourth *d* 30, and the fifth *e* 25; and moreover, if all the pinions into which these wheels pitch have six leaves or teeth; then, in the time that the first wheel *a* makes a turn, the pinion *f* will make 4812½ revolutions; but the ratchet R, which the first wheel *a* carries, is commonly divided into 24 parts, the half of which are afterwards taken away, in order that there may remain only 12 to strike 12 blows for the 12 hours. If, then, we divide 4812 by 24, we shall have the number of turns that the fifth pinion makes for each blow of the hammer, which gives 200½ turns of the pinion *f* for one tooth of the ratchet R.

The first wheel *a*, or great wheel of the striking part, carries a click and a spring, on which act a small ratchet, put under the ratchet wheel R, which forms click and ratchet work, like what has been seen in the first wheel of the repetition (Plate CCCV. Fig. 1.) which has the same use; that is to say, when we push the pendant or pusher, the ratchet R retrogrades, without the wheel *a* turning; and the spring which is in the barrel B (Fig. 2.) bringing back the ratchet R, on whose arbor *g*, the inner end of the spring is hooked; the small ratchet comes butt against the click, and turns the wheel *a*; and the ratchet R makes the hammer M to strike, whose arm *m* is engaged with the teeth of this ratchet.

The spring *r* attached to the plate (Fig. 2.) acts on the small part *n* of the arm *m* (Fig. 1.) The effect of this spring is to press the arm *m* against the teeth of the ratchet; so that when we make the watch to repeat, the ratchet R retrogrades, and the spring *r* brings always back the arm *m*, in order that the teeth of the ratchet may make the hammer to strike.—Let us now pass on to the description of the motion work.

Plate CCCVI. Fig. 3. represents that part of a repeater which is called the dial or motion work. It is seen in the instant where the button or pendant is just pushed home to make it repeat. In first taking off the hands, and then the screw which fixes the dial of repeating watches, we will see the same mechanism that this Figure presents. This is the kind of repeating motion work most generally adopted; it is solid, and of easy execution. P is the ring or bow to which the pendant shank or pusher is attached, and this enters into the socket O of the watch case, and moves within it its whole length, in tending towards the centre. It carries the piece *p*, which is of steel, and fixed in the pendant shank, both composing the pusher; the under side is filed flat. A plate of steel fixed to the case inside, prevents it from turning round about, and permits it to move lengthwise only. The end part of the steel in the pusher is formed so that it cannot come out of the case socket, this being also prevented by the small steel plate.

The end of the piece *p* acts on the heel *t* of the rack CC, whose centre of motion is at *y*, and at whose extremity *c*, is fixed one end of the chain *s s*. The other end keeps hold of the circumference of a pulley A, put by a square on the prolonged arbor of the first wheel of the runners. This chain passes over a second pulley B.

If, then, we push the pusher P, the end *c* of the rack will describe a certain space, and, by means of the chain *s s*, will cause the pullies A, B to turn. The ratchet R (Fig. 4.) will also retrograde, until the arm *b* of the rack comes upon the snail L; then the main spring of the repetition bringing back the ratchet, and the pieces which it carries, the arm *m* will present itself to the teeth of the ratchet, and the hammer M will strike the hours, of which the quantity depends on the step of the snail, which is presented to the arm *b*.

In order to have a better idea of the effect and disposition of this repetition, it is only necessary to look at Fig. 4. where the rack *y c* is seen in perspective; the hour snail L, and the star wheel E; the pullies A and B, the ratchet R, the wheel *a*, the part of raising *m n* of the hour hammer; and these are the principal parts of a repetition, which are drawn as if they were in action.

The snail L is fixed to the star E by means of two screws; they both turn on the pivot formed from the screw V, carried by the all or nothing piece T R, moveable on its centre T; the all or nothing piece forms with the plate a sort of frame, in which the star and hour snail turn.—Let us now see how the quarters are repeated.

Besides the hour hammer M, there is another N, (Plate CCCVI. Fig. 1.), whose arbor or pivot comes up within the motion work, and carries the piece 5, 6 (Plate CCCVI. Figs. 3, 4.) The prolonged pivot of the hour or great hammer passes also within the motion work, and carries the small arm *q*: these pieces 5, 6 and *q*, serve to make the quarters strike by double blows. This is the effect of the quarter rack Q, which has teeth at the ends F and G, that act on the pieces *q*, 6, and cause the hammers to strike. This piece or rack Q is carried about by the arm *k*, which the arbor of the ratchet R has on it, by a square above the pulley A, in such a manner, that when the hours are repeated, the arm *k* acts on the pin G fixed in the quarter rack, and obliges it to turn and raise the arms *q* and 6, and consequently the hammers.

The number of quarters which the hammers must strike is determined by the quarter snail N, according to the depth of the steps *h*, 1, 2, or 3, which it presents: the quarter rack Q, pressed by the spring D, retrogrades; and the teeth of the rack engage more or less with the arms *q*, 6, which get also a retrograde motion, and are brought back by the springs 10 and 9: The arm *k* bringing back the quarter rack, its arm *m* acts on the extremity R of the all or nothing TR, the opening of which at *x*, traversing against a stud fixed to the plate, allows R to describe a small space: the arm *m*, coming to the extremity of R, this last pressed by the spring *i x*, is made to return into its place, so that the arm *m* rests on the end R, and by this the quarter rack cannot fall or retrograde, unless the all or nothing piece is pushed aside. The arm *u*, carried by the quarter rack, serves to overturn or set aside the raising piece *m*, (Fig. 4.) (which is moveable on the arbor of the hour hammer,) whose pin 1, comes up within the motion work; so that when even the hours and quarters are repeated, the quarter rack still continues to move a little way, and the arm *u* turns aside the raising piece *m*, by means of the pin 1, which comes within the motion work, and by this it is put from having any holding with the ratchet R, so long as the all or nothing TR does not allow the quarter rack to retrograde or fall; which can only happen in the case when, having pushed home the pendant against the snail, the arm *b* of the rack CC presses the snail, and makes it describe a small space, at the extremity R of the all or nothing: then the quarter rack will fall and disengage the becs or lifting pieces, and the hammers will strike the hours and quarters, given by the snails L and N.

The great hammer carries a pin 3, Fig. 4. which comes up to the motion work through an opening marked 3, Fig. 3.: the spring *r* acts on this pin, and causes the great hammer to strike: this hammer carries another pin 2, which passes also through to the motion work by an opening 2, Fig. 3.; it is upon this that the small tail of the raising piece *q* acts, to make it give blows for the quarters: the small hammer has also a pin which passes through to the motion work by the opening 4; it is upon this pin that the spring 7 presses, to cause the quarter hammer to strike. The spring S is the spring jumper, which acts on the star wheel, E.

Figure 6. represents the cannon pinion and the quarter snail N, seen in perspective. The quarter snail N is

rivetted on the cannon pinion *c*, the end of which D carries the minute hand; this snail N carries the surprise S, the effect of which is the same as that for the repeating clock; that is to say, when the pin O of the surprise shifts the place, or causes the star to advance, and the jumper having done turning it, one of the teeth of the star comes to touch the pin O which is carried by the surprise, and causes the part of the surprise Z, Fig. 3. to advance, so that when the arm Q of the quarter rack falls on this part Z, and prevents it from falling on the step 3 of the snail; by this the piece repeats only the hour. The changing from one hour to another is by this way made in an instant, and the watch strikes the hour exactly as marked by the hands. The socket or cannon of the cannon pinion *c* D, Fig. 6. is slit, in order that it may move spring tight on the arbor of the second wheel, on which it enters with a degree of stiffness or friction, slight enough to be able to turn easily the minute hand to either side, by setting it back or forward according as it may be required, which sets also the hour hand to the hours.

It is proper here to undeceive those who think that they injure their watches in setting the minute hand backward. In order to convince one's self that there is nothing in this, it is sufficient to remark the position which the pieces must have in a repeating motion work, when it has to repeat the hour, when the pendant or pusher has brought back and set aside all the pieces which communicate with the snails L, N; for at this time there is no communication or connection between the pieces of the movement and those of the motion work, but that of the pin O of the snail or surprise, with the teeth of the star wheel E, which nothing can prevent from retrograding. If then the minute hand is made to make a complete turn backward, the pin O will also make one of the teeth of the star to retrograde; and if the watch is made afterwards to repeat, it will strike always the hours and quarters as marked by the hands. But it must be observed, that if the hands were turned in the same instant that the watch is made to repeat, they would then be prevented: it is necessary then, before touching the hands of a repeating clock or watch, to wait till it has repeated the hour, so that all the pieces shall have taken their natural situations.

It is easy to conclude from this, that since with a repeating watch, we can set backward or forward the minute hand, according as it may be required, we may with much greater reason do this in a plain watch, where no obstacle is opposed to it.

As to the hour hand of a repeating watch, it ought never to be turned without that being done by the minute hand alone; except in that case where the repeater does not strike the hour marked by the hour hand, when it would be necessary to put it to the hour which the repeater strikes.

When the repeater gets of itself deranged, by the hour hand not according with the hour which the watch strikes, this is a proof that the jumper S, or the pin O of the snail, do not produce well the effect they ought to have.

The returning or minute wheel, Fig. 6. is placed, and turns on the stud 12, Fig. 1.: this wheel pitches into the cannon pinion N, which has twelve teeth; the wheel, Fig. 6. has thirty-six; the cannon pinion then makes three turns whilst it makes one; this carries a pinion of ten teeth, which pitches or leads the hour wheel, Fig. 7. which has forty; the wheel, Fig 8. makes then four turns for one of the hour wheel; the cannon pinion consequently makes twelve turns for one of the hour wheel, and the cannon pinion makes one turn in an hour; the hour wheel takes then twelve hours to make one revolution; it is the socket of the hour wheel which carries the hour hand. The raising or lifting piece *m*, *n*, Fig. 2. can only describe a small arc, which permits the ratchet R to retrograde; and so soon as the mover brings it back, the arm 1 of the raising piece draws the hammer M.

Figure 5. represents the under side of the all or nothing, with the two studs; one *u* as a centre on which it moves, and the other *x* on which the star and snail turn, Fig. 9.: the hole *c* of this piece allows the square of the fusee of the movement to come through, and lastly, passing through the dial, serves for winding up the watch. W, Fig. 3. is the locking spring and bolt; this is what prevents the movement from opening out of the case.

Y is a small cock or bridge which keeps the rack to its place, and prevents it from getting away from the plate, permitting it to turn only on its own centre.

All the parts of the repetition or motion work, which have been described, are placed on the back of the pillar plate, and are covered by the dial; so that between the plate (Fig. 3.) and the dial there must be an interval, to allow sufficient play for the motion-work: It is for this purpose that a piece is destined, which is not represented here, and which is called the brass edge. This is a sort of circle, or ring, into which the circumference, or edge of the pillar plate, is sunk a little way, with which it is kept fast by means of keys, or griffs 13. and 14. The brass edge is covered by the dial, fixed after that of the brass edge, by means of a screw.

A repeater is made to strike the hour which it indicates the moment we press in the pendant; so that the machine must be contrived in such a way, that it may be easy to push in the pendant, and that the blows of the hammers may be the strongest possible. With respect to the first, that depends on two things; the given force of the spring, and the length of the pusher; that is to say, the space described, and the manner of making the pusher act on the rack. With regard to the last, the rack must be placed in such a manner, that the point of contact of the pusher follows the arc described by the rack, in such a way that the force shall not be decomposed, so that the action of the hand on the pusher shall act wholly upon the rack.

With regard to the pusher, its length depends on the point where it acts on the rack; that is to say, according as it acts farther or nearer the centre of motion. It is obvious, that if it acts near the centre, more force is required, and it will describe a less space, and *vice versa*. As to the force of the blow of the hammer, it is limited by the force of the repeating main-spring, and by the force that the runners require to move or keep them in motion; for it is clear, that it is only the excess of the force of the spring over the resistance of these wheels that can be employed to raise the hammer. The number of blows of the hammer, for one revolution of the ratchet, determines again the force of the blow.

## CHAP. IX.

### *On Compensation Pendulums.*

Compensation Pendulums are those which are constructed to counteract the effect of heat and cold, in lengthening or shortening a pendulum rod.

Godfroi Wendelinus, Canon of Condé in Flanders, who published a dissertation, in 1626, on the obliquity of the ecliptic, seems to have been the first who observed that, by change of temperature, metals changed their lengths.

Graham was the first person who thought of making a pendulum rod that should conteract the effects of heat and cold on it, by a combination of rods or wires of different metals, such as brass, silver, steel, &c ; but he never put it in execution, from the opinion that it would not be effectual enough in its operations. It occurred to him at the same time, that mercury, from its great expansion by heat, would be more adapted to the end he was in pursuit of. Having made a pendulum on this principle, it was applied to a clock, and set a-going. It is described in the *Philosophical Transactions*, No. 392, in a paper which was given into the Society in 1726. He says, " the clock was kept continually going, without having either the pendulum or the hands altered, from the 9th June 1722, to the 14th November 1725, being three years and four months." Some time previous to 1726, Harrison, being then at Barrow in Lincolnshire, was engaged in making experiments on brass and steel rods with the same view, and produced what is now called the " Gridiron Pendulum." See *Description of two Methods*, &c. by John Ellicott, F. R. S. London, 1753.

Some estimate may be formed of the advantages of a compensation pendulum, by comparing the going of a clock which had one with that which had a simple pendulum, as shewn in a letter from Mr Bliss, at Oxford, dated 12th July 1752, to Mr Short, in London. " I find, upon examining my book, that the greatest difference in the going of the clock, between the coldest weather of the two last winters and the hottest weather of the two last summers, is no more than one second per day; and this was occasioned by the levers being made too short, of which I advised Mr Ellicott above a year since: Whereas a clock with a simple pendulum and brass rod, made by Mr Graham, and which belongs to Dr. Bradley, in the coldest weather, lost above fifteen seconds per day, and in the warmest gained above thirteen seconds per day, and went very near the equal time in temperate weather." It is plain that Mr Bliss must have meant *gained* in the coldest weather, and *lost* in the hottest, otherwise there would be no analogy with the effect of the temperature in summer and winter on the brass pendulum rod. See Ellicott's pamphlet, already quoted.

### *Graham's Mercurial Pendulum.*

The mercurial pendulum, invented by Graham, having been the first that was applied to a clock for the purpose of compensation, we shall begin with the description of it, taking the others nearly in the order of their invention. This pendulum consists of a pendulum rod, which carries a large glass jar filled with mercury, so that the expansion or contraction of the rod may be counteracted by the opposite expansion or contraction of the mercury. To make this pendulum in the way which has hitherto been adopted, is attended with considerable trouble. From the nature of the material, the construction of such a pendulum must always be troublesome, because any filling in, or taking out of the mercury from the cylinder or glass jar, to bring about the compensation, will cause a change of place in the index point on the graduated arc or index plate, if such a thing is used. A pendulum which will remedy this evil will be afterwards described, so that we shall now proceed to give a description of one made in the common way.

The length of the pendulum over all, from the bottom of the sole to the upper end of the pendulum spring, was 43.95 inches; the inside bottom of the jar, .6 of an inch from the bottom of the sole ; and the height of the column of mercury in the jar, about 7.47 inches. From the upper end of the spring, take a length of 39.2 inches on the pendulum downwards, then 43 95 inches — 39.2 + 6, will give that part of the column of mercury below the centre of oscillation equal to 4.15 inches, and that above the centre 3.32 inches. The height of the jar outside, was 7.8 inches ; a wire put down inside measured 7.6 inches ; mean diameter inside, 2.018 inches ; weight 7.5 ounces. Although it would be still better to have it of a less weight, yet it is doubtful if it would be then strong enough to support such a column of quicksilver. The weight of the stirrop or cylinder frame was 1lb. 6 ounces, and was reduced 6 ounces ; that is, from the sole was taken 2.55 ounces, and from the top 3.45 ounces, both equal to 6 ounces. When the clock was set a-going after this alteration, with the pendulum the same length as before, it went slow, at the rate of 46 seconds in 24 hours, and when shortened by touching up the regulating nut, it was found to be about .15 of an inch less than the former length.

The length of the stirrup bars outside, including sole and part of the top, was 8.125 inches ; the breadth of the frame from outside of the bars, 3.25 inches ; the thickness of the pendulum rod and bars, 0 136 inch ; breadth of ditto, 0.384 inch ; thickness of sole outside, 0.515 of an inch ; distance from bottom of the sole to upper side of the jar cover, 8.187 inches ; jar sunk into the sole about or near to 0.25 inch ; distance from upper side of jar cover to under side of stirrup top, 1.25 inch ; height of stirrup top for flat of pendulum rod, 1.75 inch ; thickness of the flat, 0.220 inch ; diameter of the regulating screw, 0.218 inch ; ditto of the nut, 1.150 inch. The screw had 36.25 turns in an inch ; and the nut was divided into 30 prime divisions, each being equal to a second in a day. The prime divisions were subdivided into four.

| | Inches. |
|---|---|
| Length of stirrup bars inside | 8.05 |
| Thickness of sole outside | 0.515 |
| Length of stirrup top | 1.75 |
| From the stirrup top to the upper end of the pendulum spring | 33 485 |
| Length of the pendulum over all | 43.800 |

| | Inch. |
|---|---|
| Length of pendulum spring | .625 |
| Breadth of the double laminæ, including 164, the space between them, each lamina being .168 | .500 |
| Thickness of ditto | .007 |

| | lb. | oz. | drams. |
|---|---|---|---|
| Weight of quicksilver in the jar | 11 | 12 | 5.35 |
| Ditto of stirrup frame | 1 | 0 | 0 |
| Pendulum rod and spring, regulating nut, jar cover, &c. | 0 | 13 | 0 |
| Jar | 0 | 7 | 8 |
| Total weight of pendulum | 14 | 0 | 13.35 |

Before the pendulum was altered, the rate of the clock shewed that the compensation was not sufficiently effective, although the height of the column of mercury was 7.5 inches nearly, and the jar being full allowed no more to be put in: By reducing the weight of the jar frame or stirrup, the rod required to be shortened, as has been stated, .15 of an inch; whether or not this will be enough, remains to be determined. The daily rate for a month or six weeks was 0″.1 slow, when the temperature was from 36° to 40° of Fahrenheit's thermometer, and got gradually slower as the height of the thermometer increased. When between 60° and 66°, the daily loss was from 0″.37 to 0″.45 ; for about two weeks, when the weather was extremely cold, the thermometer at the freezing point and under, the clock showed a tendency of rather gaining.

Of late years, the mercurial pendulum has been adopted in some astronomical clocks, and it seems upon the whole to answer very well. The author of the *Elements of Clock and Watch-work* thought that it was not fit for this purpose, being too quick in its operations of expansion and contraction; but if the cover is well fitted to the top of the jar, we can venture to say, from the resistance made by the glass to any change of temperature, that the operations will be too slow; and for this reason, it is proposed to make such a pendulum with a thicker rod and stirrup bars, that they may not take heat and cold too hastily. A steel jar would perhaps answer the end as well as any other contrivance; but some would object to this, on account of the danger of magnetism. But even a jar of this kind, from its being made thin, (for it would be heavy were it as thick as the glass one,) would be easily affected by the changes of temperature; and mercury being still more susceptible of these changes, the operations of counteracting the effects of them might be too sudden.

It is of great importance that a pendulum-rod should, with the smallest quantity of matter, be as stiff and inflexible as possible; and although it was proposed to have thicker bars and rods, let us suppose the same quantity of matter is taken as before, but under a circular in place of a rectangular surface. It must in this form require more time to get heated and cooled, which is the end we now attempt to gain. The sides of the parallelogram were .384 and .136 of an inch, the sum of which, being doubled, will give 1.040 inch for the circumference of the bar. To find the diameter of a cylindrical rod containing the same quantity of matter as the parallelogram, say, as 355 is to 113, so is 1.040 to the diameter of the rod required, which will be found to be .33104 of an inch.

Let the improved jar frame, or stirrup, therefore, be composed of two round steel rods, .331 of an inch in diameter, and 8.85 inches in length, from shoulder to shoulder, at each of which pivots are formed. Those for the upper ends should be a quarter of an inch long, and of the same diameter, tapped so as to screw firm into the upper cross piece. The distance from the centres of the tapped holes, in the traverse or cross piece, requires to be 2.8 inches, in order to give freedom for the jar between the rods, the length of the cross piece over all should be 3.3 inches, and its breadth at the place where the rods are screwed in .450 of an inch. At the middle a circular part is formed, .5 of an inch in diameter, in the centre of which a hole is tapped, by which the regulating screw may raise or lower the jar, without changing the place of the index point. The cross piece may either be brass or steel, though the latter is perhaps preferable. The pivots on the lower end of the rods may be of the same diameter as those on the upper end, but a little longer, and tapped a little way in on the ends; when well fitted into the lugs of the brass sole, on which the jar rests, and sunk a little way down into it, nuts are screwed on to the ends of the pivots, and sunk in the lower side of the brass sole. Care must be taken to have the distance between the centres of the holes in the sole the same as in the cross piece, so as to make the rods stand parallel to each other. To go outside of the frame now described, another is made, to which is attached the pendulum rod, the regulating nut, and lower sole, in which is fixed the small steel index, which cannot change its place, after being once made for it. The upper cross piece for this may be of the same thickness as the former, and in length not less than 4 inches. A hole is tapped near to each of the ends, and their centres are distant from one another 3.56 inches nearly, and are wide enough to allow a round steel rod of .25 of an inch in diameter to pass freely through; the length of these rods, from the lower side of the cross piece, to the upper side of the lower sole, is nearly 10.6 inches. The lower sole may be a brass wheel, crossed into four arms, the centre part being large enough to have a hole tapped, so as to fix the steel index in it. The diameter of the wheel is the same as the length of the upper cross piece, which is 4 inches; and the thickness .25 of an inch, or a little more. This sole, in which the index is fixed, serves also as a resting part for the pendulum, when it happens to be taken from its place. The upper ends of the rods are formed into a sort of double shouldered screw; the tapped part is a little more than a quarter of an inch long, and as much in diameter; the length of the plain and tapped part of the screw is about .7 of an inch, and when screwed into the upper cross piece, it binds to it the lower end of the pendulum rod, which is formed into a shape something like a compressed $\lambda$, having lugs or soles, through which the screws for fixing it passes. The regulating screw has an untapped or plain part, which turns freely in a hole in the middle of this upper cross piece, formed in the same way as the upper cross piece for the jar frame; the nut or head of the regulating screw is shaped so as to lie under the hollow of the $\lambda$, at the lower end of the pendulum rod, and on the upper side of the cross piece; the lower ends of the rods of the outside frame are gently tapered, and fitted into holes in the brass wheel, through the edge of which are put pins to fix them and the wheel together; this outside frame has no part in the compensation. The brass cover for the jar has the lugs hollowed out a very little, so as to come in on the rods of the jar frame; the ends of the upper traverse, of which, as well as the lugs of the jar sole, are hollowed, and take in with a part of the rods of the outside frame, along which the jar frame is moved up and down. The height of the glass jar, outside, is about eight inches; and its weight and other dimensions nearly the same as those stated for the former pendulum; and the diameter of the rod and $\lambda$ part is .331 of an inch. A view of the improved mercurial pendulum is given in Plate CCCVII. Fig. 1.

Philosopers seem not to be agreed respecting the expansion of mercury relative to that of other metals; some making it 15 times, others above 16 times that of iron. In regard to the column of mercury for a mercurial pendulum, something depends on its diameter, as well as its height. Suppose the length of steel to be 43 inches, and the column of mercury 7.5 inches in height, and 2 inches in diameter, which were the dimensions used in a pendulum brought nearly to its state of compensation, we may then find how many times the expansion of this column is contained in the 43 inches. Say, as 43 inches is to 74, the expansive ratio of steel, so is 7.5 inches of mercury to its expansion for compensating the steel.

| | | |
|---|---|---|
| Length of steel 43 inches . . . . . | Log. | 1.6334685 |
| Ratio 74 . . . . . . . . . . . | Log. | 1.8692317 |
| | | 3.5027002 |

| | | |
|---|---|---|
| Height of column of mercury 7.5 inches | Log | 0 8750613 |
| Ratio 424.26 . . . . . . . . . . | Log. | 2 6276389 |
| | | 3 5027002 |

By this process, it appears that the expansion of the mercury is not quite 5.75 times that of the steel. A pendulum, whose vibrations are three or four degrees on each side of the point of rest, will require a column less in height than that which vibrates only one degree. Hence it is a very nice matter, to give precise rules for making a mercurial pendulum, that shall at once be perfect in its compensation.

If the steel rod *a b* and stirrup *b c* of a mercurial pendulum is lengthened by heat, the jar *d e* containing the mercury will, from this cause, be let lower down, and the centre of oscillation be carried farther from the point of suspension *a*; but the heat which lengthens the rod and stirrup, at the same time expands the mercury upward, and by this means the centre of oscillation is kept always at the same distance from the point of suspension, Fig. 1. When the rod and stirrup are contracted or shortened by cold, the mercury will also be contracted by it; and hence the lengthening or shortening of the pendulum rod by heat or cold, is compensated by equal and opposite expansions or contractions in the mercury.

*Gridiron Pendulum.*

The gridiron pendulum invented by Harrison, is composed of nine round rods, five of which are made of steel, and four of brass; and is represented in Plate CCCVII. Fig. 2. where the steel rods are distinguished from the brass ones by a darker shade. As it somewhat resembles the common gridiron in appearance, it hence probably received its present name. Not many years after this was produced, the French artists contrived a variety of compensation pendulums, but the gridiron seems to be the one now generally adopted by them. The first pendulum of this kind which we made was nearly thirty years ago; and knowing that Mr Cuming had some practice in this way, he was applied to, and very obligingly sent a drawing, and the different lengths for the brass and steel rods, which, on being tried some years afterwards, by means of a transit instrument, was found, on the whole, to be tolerably correct, but yet not quite so accurate in the compensation as could have been wished. From an abstract of the going of a clock with this pendulum, it appeared, that, during the temperature from 46 to 48 degrees of Fahrenheit's thermometer, it kept mean time. A temperature 10 degrees lower, made it gain at the rate of nearly half a second in a day, and 10 degrees higher made it lose about as much.

The lengths of the rods were, outside steel rods from pin to pin 29 5 inches; centre steel rod from upper end of the pendulum spring to the pin at the lower end, 31.5 inches; inside rods, from pin to pin, 24.25 inches; from the pinning of the lower end of the outside rods to the centre of the ball, 5 inches; making in all 90 25 inches of steel, to be compensated by the brass. Outside brass rods, from pin to pin, 26.87 inches; inside ditto, 22 25 inches, being in all 49.12 inches of brass. The length which the brass ought to have may thus be found by the inverse rule of proportion. As 90.25 inches is to 74, the number for the expansion of steel according to Berthoud, so is 121, that of the expansion for brass, to the length of brass required; that is, $90.25 \times 74 \div 121 = 49.4$ inches, the length required. Although the deficiency of brass here is very little, yet to remedy the compensation, a greater number of inches, both of steel and brass, must be taken, before this pendulum can be made complete. A description of such a one shall now be given.

The length of the outside steel rods, from pin to pin in the uppermost and lowermost traverses or brass cross pieces *a b*, *c d*, is 36 inches; the next or innermost steel rods, from their pinning in the second uppermost traverse *m*, to that in the second lowermost *n*, is 35 inches; the steel centre rod, from the pinning of it, in the third lowermost traverse *o*, to the upper end of the pendulum spring, is 37 inches and $\frac{5}{8}$ of an inch, or nearly 37.628 inches; the centre C of the ball below the pinning of the outside steel rods and index rod, is 3.94 inches; the outermost brass rods, from their pinning, in the uppermost traverse to that in the second lowermost, is the smallest quantity possible less than 35.5 inches; the innermost brass rods, from their pinning in the second uppermost traverse to the third lowest one, is 34.5 inches. The whole length of the steel is then 112.568 inches, and that of the brass 70 inches. The diameter of the rods is a quarter of an inch each. The distance from the centres of the two outside steel rods, is 2.5 inches. The rods are placed equidistant from one another, only there is a little more space left between the two brass rods nearest the centre and the steel centre rod, in order to give room for the fork to come in and clip the centre rod. The two outside steel rods are prolonged below their pinning in the lowest traverse, as seen below *c d*, about five or six inches within the ball, in order to keep it properly flat in the plane in which the pendulum should swing. In the centre of the lowest traverse *c d* is pinned a steel rod *e f*, somewhat more than a quarter of an inch in diameter, and about nine inches long. This rod goes through the centre of the ball, the index point *f* being on the lower end of it, and it is tapped for an inch in length at that part which lies near to the centre of the ball. A cross piece of brass is fixed to the inside of the ball before casting it, the lowest side of which is in a line across the centre horizontally. The ends of the two outer steel rods, and the centre or index rod, come easily through this cross piece of brass. A hollow tube comes up within the ball, as far as the under side of the inside cross piece, on the end of which, where the cross piece and ball rest, is fixed within it a tapped nut, which screws on the tapped part of the index rod. On the lower end of the tube is soldered a sort of flat conical head or nut *h*, nerrelled on the edge outside, and whose diameter may be an inch or an inch and a quarter. On the upper surface of this nut are traced two circles, in order to put divisions between them, and figures so as to correspond with the turns of the screw in an inch. A small steel index *i* is screwed on to the lower part of the ball, to point at these divisions. The lower end of the tube is a very little below the edge of the ball, that it may rest freely on the upper end. The total length, from the upper end *g* of the pendulum spring to the index point *f*, is 47.75 inches, a length of radius which will require the length of a degree on the index plate to be .833142 of an inch. The distance from the upper end of the pendulum spring to the centre of the ball, is 42 5 inches very nearly, so that the centre of the ball is about 3.3 inches below the centre of oscillation. The lowermost traverse *c d* may be about half an inch thick, and its length and breadth such, as to give it sufficient strength to receive the outside steel rods, and the centre or index rod: The uppermost traverse *a b* is nearly of the same dimensions. The second lowermost traverse *n*, and the second uppermost *m*, are nearly of the same size, and almost equal to that of the uppermost and lowermost; only they are a little shorter, having in their ends a sort of half hole, through which, in the second lowermost traverse, the outer steel rods pass easily; and through these, in the second uppermost traverse, the outside brass rods freely pass. This traverse is, of course, a little shorter than the second lowermost. In the second lowermost traverse is pinned the ends of the outermost brass rods, and in the second uppermost traverse are pinned those of the innermost steel and brass rods. In the third lowest traverse is pinned the innermost brass rods and the centre steel rod: The dimensions of this are nearly the same as the second uppermost and lowermost, only shorter, having a half hole at the ends, through which the inner steel rods pass freely. There is a hole in the middle of each of the two uppermost traverses, through which the centre rod can pass freely. Towards the lower ends of the centre steel rod, and those of the innermost brass rods, are two sets of holes, by which the third or lowermost traverse can be moved or shifted up either three or six inches, should the compensation be found in excess. It would be convenient, when shifting, to have a piece similar to the third lowest traverse, and three spare pins. This piece being like a half of the traverse, it may then be applied to the three rods, and pinned, but not to the place where the shifting is to be made. This piece will prevent the rods shifting away from one another, and will allow the traverse to be moved and fixed to the intended place. Two thin pieces of brass *p q*, *r*, *s*, must be provided, having nine holes in them, so that all the rods can move easily through them, the two outermost holes being kept rather a little tighter than the others. These pieces are intended to prevent any tremulous motion in the rods or pendulum, and are put at the same distance from the upper and lower traverses, as shewn in the figure. The pendulum ball is composed of two frustums of equal cones; the greater diameter is seven inches, the lesser four inches, and the height half an inch, giving, by calculation, 24 3474 cubic inches, the weight of which in lead is 9.997 lb. The ball, when filled with lead, together with the shells and inside cross piece, weighed 10 lb. 8 oz.: The weight of the brass and steel rods, traverse pieces, pendulum spring, and top piece, &c. was 5 lb. 13 oz.; in all, 16 lb. 5 oz. The clock to which this pendulum was applied was a month one, and was kept going by a weight of 7 lb. 7 oz. We cannot help thinking, that this pendulum is fitted up in a much better style than either Cuming's or Berthoud's.

The third lowest traverse being shifted up three inches, there will then be this quantity less for lengths of brass and steel than has been stated. The steel will be 36+35+37.628+3.94—3=109.568 inches, and the longest brass rods may be taken at 35.49+34.5—3=66.99. Their lengths and expansive ratios may be given thus:

| | |
|---|---|
| Steel 109.568 inches . . | Log. 2.0396838 |
| Ratio 74 . . . . . . . | Log. 1.8692317 |
| | 3.9089155 |
| Brass 66.99 inches . . . | Log. 1.8260100 |
| Ratio 121 . . . . . . . | Log. 2.0827854 |
| | 3.9087954 |

The difference in excess of compensation is here extremely small, and is on the side of the steel rods, being scarcely an inch too much. In taking into account the lengths of the rods, those on one side along with the centre rods are only taken; those on the other side serve as a kind of counterpoise, for giving an appearance of uniformity to the pendulum, and for preventing the weight of the pendulum ball from bending the rods, which it would do, were they all on one side. A considerable time after the gridiron pendulum was produced, some adopted zinc rods in place of brass; and, from their greater expansibility, fewer were requisite, three of steel and two of zinc being sufficient for the compensation; but such of them as we have seen, appeared to have the zinc rods of a greater length than they should have been, according to the comparative expansions of zinc and steel. There was also a large cavity in the upper part of the ball, for lodging the lower traverse, which took away much of its force; and the holes for shifting, to adjust the compensation, being at the upper ends of the rods, rendered it very inconvenient.

The following dimensions should answer very well for a pendulum of this sort. The length from pin to pin in the upper and lower traverses of the two outside steel rods should be 27 inches, and 5 or 6 inches more beyond the lower traverse, to go within the ball, for the same purpose that was mentioned in one having the brass rods; from the pin, in the lower end of the centre steel rod, which is in a traverse just above the lower one, to the upper end of the pendulum spring, should be 36.75 inches; from the pin in the lower end of the centre rod to the centre of the ball, 4.75 inches, being in all 68.5 inches of steel. The diameter of the steel rods should be .25 of an inch. In the upper traverse is a hole, through which the centre rod must pass freely. The length of the zinc rods, from the pin in the upper traverse to that in the upper of the lower traverses, is 25.34 inches, and their diameter .27 of an inch. There may be holes in the lower ends of the centre and zinc rods, for adjusting the compensation, as in the case of the brass rods. The ends of the upper and lower traverses must have half holes, taking in with the outside steel rods; pieces for tremulous motion, and manner of fitting up the pendulum ball, and regulating nut, &c. as has been already described.

The lengths and expansive ratios may be put thus:

| | |
|---|---|
| Steel 68.5 inches . . . . . . | Log. 1.8356906 |
| Smeaton's ratio for steel 138 inches | Log. 2.1398791 |
| | 3.9755697 |
| Zinc 25.34 inches : . . . . . | Log. 1.4038609 |
| Do. for zinc 373 inches . . . . | Log. 2 5717088 |
| | 3.9755697 |

The zinc which is used in these pendulums must always be understood to be that which is hammered half an inch per foot, which seems to have even more expansion than Smeaton has stated; but whether it expands as much as Ward makes it, still remains to be determined.

In taking into account, by this process, the comparative expansion of the brass and steel rods, it must be observed, that the steel rods have their expansion downwards, while the brass rods expand upwards; so that when heat expands the steel rod downwards, the brass rods acting in a contrary direction upwards, tend always to keep the centre of oscillation at an equal distance from the point of suspension; and hence the length of the pendulum is constantly the same. In like manner, if cold contracts the steel rods, it will also contract the brass rods, so as still to keep the pendulum at as invariable a length as can possibly be attained by any method that human ingenuity can propose. The comparative lengths of the brass and steel rods may be computed by any other expansive ratio than those of Berthoud's, which we have used; such as those of Smeaton, or of that ingenious artist Troughton. Their differences will vary a little from Berthoud's; but it will be very trifling. It will require long experience to know which are the best founded, as the going of astronomical clocks may be affected by other causes which have no connection with the compensation of the pendulum rod.

### *Ellicott's Pendulum.*

Not many years after Harrison's pendulum was known, Mr Ellicott, and some of the French artists, contrived compensation pendulums in different ways, most of them having the ball adjustable by levers, which can never be equal to those in which the expansion and contraction act by contact in the direct line of the pendulum rod. Mr Ellicott was a very ingenious artist of the old school, as appears from several of his works, and his pendulum evinces great ingenuity in its construction.

Ellicott's pendulum, shewn in Plate CCCVII. Fig. 3. consisted of two bars, one of which *a b* was of brass, and the other of iron or steel. Mr Cuming conceived, that where there were two bars only, a flexure and unequal bearing would take place, and therefore an exact compensation could not be effected. To remedy this, he constructed the pendulum with two steel bars and one bar of brass, as shewn in Fig. 4. No. 3. Into the lower end of the brass bar *a b*, Fig. 4. was let one half of the diameter of a small steel roller *r*, the other half being let into a moveable brass piece having two short arms 1, 2. These arms, by the levers *m o* 2, *n o* 1, moving round *o*, *o* as fulcra, make the roller press equally on the lower end of the brass bar. The steel roller marked *r*, has a fillet raised up on each end, for the purpose of keeping this part of the brass bar at an equal distance from the steel bars. The length of the brass bar *a b* should be 39 25 inches from the upper end, which is square, to the lower end, which is rounded, its breadth three quarters of an inch, and its thickness at least one-eighth of an inch. The steel bars are in length, from the upper square ends to the centre of the ball, nearly where the short arms of the levers act on the moveable brass piece, about 39.75 inches; and the bars are left broader here, so as to be about one inch and a quarter; and this breadth is prolonged below the end of the brass bar three quarters of an inch or more. The thickness of the steel bars is one-tenth of an inch, and their breadth three quarters. The back steel bar has no opening in it; but the front bar has one, which is represented in the drawing at A, Fig. 4. No. 2. In order to see the action of the levers on both arms of the moveable brass piece, a cavity *s s*, Fig. 3. is left for this purpose in the ball. A piece of glass is inserted in the opening, so as to prevent dust from getting into this part of the pendulum. This broad part of the steel bars serves as a kind of frame, on which are screwed two pieces of brass of the same figure as the steel bars, to connect them with that steel part of the lower end of the pendulum rod which goes through the ball, on which is a nut and screw, and a strong double spring *m n* in Fig. 4. for the purpose of taking off somewhat of the weight of the ball, according as it bears too much or too little on the short arms of the levers. The levers are shewn at No. 2, 3; the screws, and lower end of the pendulum rod in Fig. 4; the nut N, and double spring SS, in Fig. 3. The use of the nut and screw is to adjust the strength of the spring, as they have nothing to do in the regulation of the pendulum for time to the clock, which is done by an apparatus for this purpose at top, connected with the pendulum spring. In the brass pieces which are screwed on to the broad part of the steel bars, the pivots of the levers *a*, *a* turn. There is a piece of brass put on at top, formed so as to interpose a little way down between the brass bar and the steel ones, keeping them at a proper distance from one another. The sides near to the square ends of the bars and this piece of brass are firmly pinned or screwed together. It is in this piece of brass that the lower end of the pendulum spring is fixed; the upper end being fixed to a piece, which is moveable up and down in a fixed frame by a nut and screw. The pendulum is lengthened or shortened, according as the pendulum spring is let out or brought within that part of the frame through which the spring passes. The bars of the pendulum are connected by four or five screws, equal spaces being taken for their places between the centre of the ball and the square or upper ends of the bars. The back bar is tapped to receive the screws, which go through holes made in the front steel bar, to let them easily pass. On the shank or body of the screws, are fitted hollow cylinders either of brass or steel, and of such a length, that when the screws are put home there shall be no pinching of the front steel bar by the head of the screws. Rectangular openings are made in the brass bar, for the hollow cylinders to come through, whose length may be about equal to twice the diameter of the cylinders, and so that the brass bar may easily move on them, by any small motion they may have in contracting or expanding. On each of these cylinders is put two loose brass collets or washers, one between each steel bar and the brass bar to keep them free of each other. Their thickness should be at least .04 of an inch, so as to allow the air to pass freely between the bars. The small hollow cylinders through which the screws pass when connecting the bars, should go easily into the front steel bar, the lower base bearing on the inside of the back steel bar. The upper base should be above the surface of the front bar fully more than the thickness of strong writing paper, so that when the screw is put home the shoulder of it may not pinch the bar. The edges of all the bars should be chamfered off from each side, so as to form an angle in the middle plane of their thickness, for the purpose of giving them a lighter appearance, and making them less susceptible of the resistance of the air. The diameter of the pendulum ball may be seven inches and a half, and its thickness at the centre about two inches and a quarter. In the edges, and in the line of the diameter horizontally across, are placed two long and stout screws, *g g*, Fig. 3. whose heads have graduated circles on them, and are near the edge of the ball, and an index *i*, *i* to each. The inner ends of the screws shewn at *s*, *s*, are turned of such a shape, so as to apply by one point only on the long arms of the levers *m*, *n*, as seen in Fig. 3. The front shell of the pendulum ball is fixed on by four screws. It has been objected by some, that, from the weight of the ball, the brass rods in a compensation pendulum are compressed, and the steel rods stretched; a matter of no moment whatever, in our opinion. This may, however, in some degree, be remedied in Ellicott's pendulum, by making the brass bar of such a length, as to come through and below the lower edge of the ball, in place of the steel part, which was common to both steel bars, as has just now been described. This part of the brass bar is tapped, having on it the nut and strong double spring, which takes off a part of the weight, as has been noticed. A certain portion of the weight of the ball will in this case bear on the brass bar; supposing it one-third of the weight, the remaining two-thirds will be carried jointly by the steel bars. Although the brass bar is here carried through the ball, it is easy to put a piece to it, moveable on a pivot in the middle of the bar, having two lugs applying to the edges of the bar, on which the short arms of the levers *a*, *a* may act, as was the case in the other by the moveable brass piece.

Things being in this situation, let us suppose that the bars composing the pendulum rod are lengthened by heat, and that the brass lengthens more than the same length of steel does; then the brass bar *a b*, by its excess of expansion, will press down the short ends of the levers, *m*, *n* at *b*, and consequently raise up the ball, which, by the screws *s*, *s*, rest on the long arms *m*, *n* of the levers; and provided the ends of the screws press on the levers at a proper distance from the centres *o*, *o*, the ball will be always kept at the same distance from the point of suspension, notwithstanding any alteration the rod of the pendulum may experience from heat or cold. What this distance ought to be may very nearly be determined, if the difference of the expansion between brass and steel is known; for the proportion which the shorter arms of the levers ought to bear to the longer ones, will always be as the excess of the expansion is to the whole expansion of the steel. Instead of the brass heads of the screws being placed near the outer edge of the ball, they may be more advantageously placed within the ball, at the distance of about an inch and a quarter from the edge, as shewn in Fig. 3.

See *Phil. Trans.* 1751, p. 479, and a pamphlet which Mr Ellicott published in London 1753. For an account of the improvement made upon it by Mr A. Cuming, see his *Elements of Clock and Watchmaking*, p. 107.

*Smeaton's Pendulum.*

Mr Smeaton's compensation pendulum consists of a glass rod AB, half an inch or more in diameter, and 45.5 inches long. To the upper end is fixed the pendulum spring; to the lower a screw *s* and regulating nut *n*. A brass tube or ring *m*, Fig. 5. of an inch or so in length, is put to move easily on the lower end of the rod, having a fillet at each end, one bearing on the regulating nut, the other supporting the zinc, iron, and lead tubes, which compose what may be called the pendulum ball. The zinc cylinder or tube is $12\frac{1}{4}$ inches in length, $\frac{1}{8}$th of an inch thick, and fits easily on the glass rod, the lower end resting on the upper fillet of the brass ring. On the zinc tube is put another of iron, 12 inches long, and $\frac{1}{8}$th of an inch thick, easily moveable on the zinc tube, with a kind of bottom to it, in which is a hole for the glass rod to go freely through. The bottom is uppermost, and rests on the upper end of the zinc tube. The lower end of the iron tube has a fillet on its outside, on which rests a leaden tube of 12 inches long, and $\frac{1}{4}$th of an inch thick, and which goes easily over on the iron tube. The outside diameter of the leaden tube will be nearly two inches. Although this pendulum will not be thought elegant in appearance, yet it is said to have answered the purpose of compensation very well. A section of the rod is shewn in Fig. A.

As glass does not suffer much expansion or contraction from heat or cold, it will be the more easily compensated. The glass rod AB of this pendulum being supposed to lengthen in a small degree by heat, is compensated by a zinc tube of twelve inches and a quarter long, whose lower end resting on the lower end of the glass rod, would be carried down by the lengthening of the glass rod, but the same cause which produces this, will make the zinc tube expand upwards, which will carry up the iron and leaden tubes. The iron tube has in this case its expansion downwards, and the leaden tube compensates this by having its expansion upwards.

*Reid's Pendulum.*

Mr Thomas Reid's compensation pendulum is composed of a zinc tube AB, and three steel rods, *ab*, *cd*, *ef*. In order to obtain a proper tube, the zinc must be very gently fused into a bar about an inch square, and 24.25 inches long, and the mould into which it is poured should be upright, or nearly so. Let this be very carefully hammered to half an inch per foot, meanwhile keeping it pretty warm, to prevent cracking or breaking. After this operation, a hole is pierced straight through the bar, from end to end, and opened up by means of a clean cutting broach, until it is .450 of an inch, or so, in diameter. The outside may be turned down till it is .7 of an inch, or less. The length should be 25.34 inches, the same as the zinc rods were taken at. The steel rods must be a quarter of an inch in diameter; the length from pin to pin, in the upper and lower traverses of the two outside steel rods *c d*, *e f*, 27 inches, five or six inches more being prolonged to go within the ball. In the middle of the lower traverse *m n* is pinned a steel rod *g h*, somewhat more than a quarter of an inch in diameter, and nine inches long, which comes through the centre of the ball, which is fitted up in the same way in every respect as was described for the gridiron pendulum. The steel centre rod *a b* goes up inside of the zinc tube, from the pin which is in the lower end of it, which is in a traverse, a very little above the lower one, to the upper end of the pendulum spring, 36.75 inches; from the pin in the lower end of the centre rod, to the centre of the ball, 4.75 inches. A hole in the upper traverse *o p* allows the centre rod to pass freely through. The lower end of the tube rests on the traverse *g r*, in which the centre rod is pinned. The upper traverse bears on the upper end, both traverses having a part turned from them, about one-tenth of an inch in height, and of such a diameter as to go into the ends of the tube, for the purpose of keeping it to its proper place. The distance from the centre of the holes in the upper and lower traverses, about 1.25 inch, which will be enough to make the two outside steel rods stand clear of the zinc tube. A thin piece of brass, with three holes in it for the outside steel rods and tube, might be put half way between the ends of the tube, to prevent any bending, or tremulous motion, a thing, however, not likely to take place. It would be proper to have a few holes in the tube, for the purpose of admitting air more freely to the centre rod.

The centre steel rod *a b*, when lengthened by heat, will make the lower end B of the zinc tube, (which is supported by the lower end *b* of the steel rod *a b*,) descend with it, but the same cause which lengthens the steel rod *a b* downwards will expand the zinc tube AB upwards, and this will carry up the two outside steel rods with which the ball of the pendulum is connected; their expansion downwards, as well as that of the centre rod, is compensated by the upward expansion of the zinc tube. The length of the steel rods and of the zinc tube, has been shewn to be in proportion to their expansive ratios.

It is about fifteen years since we contrived and made this kind of compensation pendulum, which seems to do very well. The following is of another kind, but we never had it put in execution, although there is no doubt but it would serve the purpose extremely well, notwithstanding the risk arising from the brittleness of the glass.

Provide a white glass tube, whose outside diameter is $\frac{5}{8}$ths of an inch, its inside diameter $\frac{3}{8}$ths, and its length 54 inches: Such a tube may be supposed equal in strength to a solid glass rod, and will be considerably lighter. Make a zinc tube from a square bar, hammered, &c. in the same way as has just now been directed, its length being 16.3 inches, and its inside diameter $\frac{5}{8}$ths of an inch, or as much more as will allow it to move freely up and down on the outside of the glass tube. If the thickness of the zinc tube is $\frac{1}{8}$th of an inch, it ought to answer very well; if it is somewhat greater, it may answer better. There must be a core of brass fitted to each end of the glass tube, ground gently into the glass, and fixed in by some of the lime cements. To make the fixing more secure, a hole might be bored through the tube and core, about half an inch from each end of the tube, and a copper pin put through them. The core in the lower end must have a small cylindrical piece, or wire, formed from it of .3 or .4 of an inch in diameter, stretching 1.5 inch beyond the end of the glass tube, and tapped for the nut inside of the zinc tube to work upon. The regulating nut should be under the pendulum ball, yet a little free of it, as it would be difficult to get at it, were it placed near the lower end of the rod. The core at the upper end has also a part of the brass, a little way above the end of the tube, for the purpose of fixing in the pendulum spring. The zinc tube goes up to the centre of the ball, which rests on the end of it; the lower end, having the tapped nut in it, bears on the regulating screw. The nut may be either soldered into the tube or not, provided it is fast there. As both the glass rod and zinc tube are round, and go through the ball, it will be requisite to have something to keep the ball to its proper swinging position. For this purpose, let a brass tube of an inch and a half in length be fitted strongly spring tight on the glass rod, and put on above the upper edge of the ball. To the lower end of the brass tube or socket is fixed a traverse piece, into which are fixed two steel rods, a quarter of an inch in diameter, and 6 inches long. These go within the ball, in the same manner as the lower ends of the outside steel rods in the gridiron pendulum. The distance between the holes in the traverse should be 3 inches, that is, each rod should be distant outside 1.5 inch from the centre of the glass tube. When the traverse with the spring tube is once set, so that the ball may have its proper position, it cannot be easily altered. The length taken for the zinc tube is rather in excess for the compensation of the glass rod, and should it be found so, the tube can readily be shortened. As the glass rod is not very fit for the pendulum fork to work on, the following apparatus is proposed, and has been found in other cases to answer the end as well as could be wished. See Plate CCCVII. Figs. 7 and 8.

AA is a hollow cylinder of brass 1.5 inch long, which fits the glass rod rather more than spring tight. It is made a little thin near the ends, and at the middle it is left thick, having the appearance of a brass ring *a, a, a, a*, formed on the cylinder, into which are fixed two pivots *p p*, a piece of brass not very thick, .3 of an inch broad, being bent up nearly in a bow form, as at B, B, having a small hole at each end, *b b*, to receive the pivots *p p*. One of the ends must be screwed on, in order to get the pivots more conveniently into their holes. At the end or middle of the bow is a solid or round knob of brass C, in which is a hole tapped to receive the screw D, the head of which is nerrelled on the edge, and sunk on the outside, to receive the round flat piece of brass E, which snaps easily in like a barrel cover, and is not left so tight, but that it may be easily turned round in its place, without any risk of coming out, and supposed to have no shake outwards. Into the piece E is fixed a piece of brass, having a hole in it to receive the pin of the crutch. Two views of this piece are seen at F F. When these pieces are all combined to act in their places, it can easily be seen, that by turning the nerrelled head of the screw D, holding the piece F in its front view position, the crutch pin will be made to move out or in, according as the screw D is turned, by which the clock will be set in beat, to a degree of nicety which is not easily obtained by bending the fork or crutch shank.

There are other modes of putting a clock in beat, but they generally consist of an apparatus for that purpose, carried by the crutch or fork, which is a load on the cock pivot. The one which has been described has the advantage of being supported by the pendulum rod.

The glass tube having a length of 54 inches, will, when expanded by heat, carry down with it the zinc tube, whose lower end rests on that of the glass tube. The centre of the ball of the pendulum resting on the upper end of the zinc tube, will expand upwards from the same cause which lengthens the glass tube, and by this means carry the ball of the pendulum up, and keep the centre of oscillation always to the same distance from the point of suspension. The length of the glass tube rod, and its expansive ratio, will be found to be in just proportion to the length of the zinc tube and its expansive ratio.

### *Troughton's Tubular Pendulum.*

Mr Edward Troughton's tubular pendulum is a very neat and ingenious one, and is in every respect worthy of that celebrated artist, to whom science is so much indebted for the great perfection to which he has brought the division of astronomical instruments.

"Fig. 9. Plate CCCVII. says Mr Troughton, drawn to a scale of one-eighth of the real dimensions, exhibits the shape of the whole instrument, in which the parts of action being completely concealed from view, it appears, excepting the usual suspension spring, to be made of solid brass. This figure gives a front view of the pendulum. This form of the bob is used more on account of its being easy to make, and sightly, than from any other considerations; it is made of one piece of brass, about 7 inches diameter, 2.5 thick at the centre, and weighs about 15 lbs. avoirdupoise: the front and back surfaces are spherical, with a thick edge or cylindrical part between them. The apparent rod is a tube of brass, reaching from the bob nearly to the top. This contains another tube and five wires in its belly, so disposed as to produce altogether (like the nine-bar gridiron of Harrison) three expansions of steel downwards, and two of brass upwards; whose lengths being inversely proportioned to their dilatation, when properly combined, destroy the whole effect that either metal would have singly. The small visible part of the rod near the top is a brass tube, whose use is to cover the upper end of the middle wire, which is here single, and otherwise unsupported.

Reckoning from the top, the first action is downwards, and consists of the spring, a short wire 0.2 diameter, and a long wire 0.1 diameter; these, all of steel, firmly connected, reach down within an inch of the centre of the bob, and occupy the middle line of the whole apparatus. To the lower end of the middle branch is fastened the lower end of the interior brass tube, 0.6 in diameter, which terminates a little short of the top of the exterior tube, and produces the first dilatation upwards. From the top of the interior tube depend two wires 0.1 diameter, whose situation is in a line at right angles to the swing of the pendulum, and reach somewhat lower than the attached tube itself, which they pass through without touching, and effect the second expansion downwards. The second action upwards is gained by the exterior tube, whose internal diameter just allows the interior tube to pass freely through it: its bottom is connected with the lower ends of the last described wires. To complete the correction, a second pair of wires of the same diameter as the former, and occupying a position at right angles to them, act downwards, reaching a little below the exterior tube, having also passed through the interior one without touching either. The lower ends of these wires are fastened to a short cylindrical piece of brass, of the same diameter as the exterior tube, to which the bob is suspended by its centre.

"Fig. 9. No. 1. is a full size section of the rod, in which the three concentric circles are designed to represent the two tubes; and the rectangular position of the two pair of wires round the middle one, are shown by the five small circles. By copying this arrangement, from the elegant construction of your own half seconds pendulum, (*Phil. Journal* for August 1799,) I avoided much trouble, which must have occurred to me, unless, indeed, I had been impelled on the same idea, by the difficulty of contriving the five wires to act all in a row, with sufficient freedom and in so small a space. Fig. 9. No. 3. explains the part which closes the upper end of the interior tube: the two small circles are the two wires which depend from it, and the three large circles show the holes in it, through which the middle and other pair of wires pass.

" Fig. 9. No. 4. is designed to explain the part which stops up the bottom of the interior tube; the small circle in the centre is where the middle wire is fastened to it; the others the holes for the other four wires to pass through. Fig. 9. No. 5. is the part which closes the upper end of the external tube; the large circle in the centre is the place where the brass covering for the upper part of the middle wire is inserted; and the two small circles denote the fastening for the wires of the last expansion. Fig. 9. No. 6. represents the bottom of the exterior tube, in which the small circles shew the fastening places for the wires of the second expansion, and the larger ones the holes for the other pair of wires to pass through. Fig. 9. No. 7. is a cylindrical piece of brass, which shows how the lower ends of the wires of the last expansion are fastened to it, and the hole in the middle is that whereby it is pinned to the centre of the bob. The fastening of the upper ends of the two pair of wires is done by screwing them into the pieces which stop up the ends of the tubes; but at the lower ends they are all fixed, as represented by No. 7. I have only to add to this description, that the pieces represented in Fig. 9. have each a jointed motion, by means of which the fellow wires of each pair would be equally stretched, although they were not exactly of the same length.

" In the apparatus thus connected, the middle wire will be stretched by the weight of the whole; the interior tube will support at its top the whole, except the middle wire; the second pair of wires will be stretched by all, except the middle wire and interior tube; the exterior tube supports at its top the weight of the second pair of wires and the bob, and the second pair of wires are stretched by the weight of the bob only.

" The first pendulum which I made of the tubular kind had only three steel wires, and one tube above the bob; that is, two expansions down and one up; and the quantity which one of brass falls short to correct two of steel, was compensated for, by extending those branches of the rod below the bob, and bringing up an external tube to which the bob was affixed. There is an awkwardness in this construction, owing to the rod reaching about 13 inches below the lower edge of the bob, otherwise it is not inferior to the one first described."

*Ward's Pendulum.*

The rod of this pendulum consists of two flat bars of steel, and one of zinc, connected together by three screws, as shown in Plate CCCVII. Fig. 10. No. 2. which is a side view of the pendulum rod when the bars are together; " *hh*, *ii*," says Mr. Ward, " are two flat rods or bars of iron, about an eighth of an inch thick; *kk* is a bar of zinc interposed between them, and is nearly a quarter of an inch thick. The corners of the iron bars are bevelled off, that they may meet with less resistance from the air; and it likewise gives them a much lighter appearance. These bars are kept together by three screws *l*, *l*, *l*, which pass through oblong holes in *h h* and *k k*, and screw into *i i*. The bar *h h* is connected to the one *k k* by the screw *m*; which is called the adjusting screw. This screw is tapped into *h h*, and passes barely through *k k*; but that part of the screw which enters *k k* has its threads turned off. The bar *i i* has a shoulder at its upper end, turned at right angles, and bears at the top of the zinc bar *k k*, and is supported by it. It is necessary to have several holes for the screw *m*, in order to adjust the compensation. No. 3, 4, 5, are a side view of each bar separately. No. 6. shows the flat side of the zinc bar. Fig. 10. No. 1. is a front view of the pendulum rod when screwed together. The letters have the same reference to the different figures."

The front steel bar being lengthened by heat, and having its expansion downwards, will carry along with it the zinc bar, whose lower end is supported by a screw in the front bar; the zinc bar in this case will have its expansion upwards, and carry up the back steel bar, whose upper end rests by means of a knee on the upper end of the zinc bar. The pendulum ball hangs to the lower part of the back steel bar which has its expansion downwards; but the two expansions downwards of the steel bars, are compensated by the upward expansion of the zinc bar.

Mr Ward's pendulum must be allowed to be a very excellent one, as it possesses the advantage of permitting the compensation to be readily and easily altered. The description which has been given of it, in the Transactions of the Society for the Encouragement of Arts, &c. for the year 1807, and in the pamphlet which Mr Ward published at Blandford in 1808, contain sufficient details to enable any common clockmaker to copy it. We have only to add, that there should be a spare screw, for shifting the compensation; and that the screws connecting the two steel bars and the zinc one should never on any account be moved. It will be found of great advantage to have a spare screw, which may be put into that place which is supposed requisite to correct the compensation; and then release the one supposed to be where the compensation is thought to be too much or too little. Our experience with it soon led us to this contrivance. Having made one of these pendulums, we shall now give an account of its dimensions, &c. The distance from the upper part of the pendulum spring to the centre of the ball, is 40.75 inches; and to the lower end of the front steel bar, 2 feet 11.5 inches. From the upper end of the zinc bar, where the back bar of steel rests or hangs on, to the centre of the ball, it is 2 feet 6.25 inches. The steel bars are forged from cast steel, and annealed; their breadth is three quarters of an inch, and their thickness about one-tenth of an inch. The length of the zinc bar is 24.8 inches; and its thickness a little more than two-tenths of an inch. The centre of the ball hangs on the end of the tube of the regulating nut, where it was tapped, to work on its corresponding screw, made near the lower part of the back bar, formed here into a round rod, the lower end of which is a point, or index, to a graduated plate fixed to the back of the case, and 5.25 inches below the centre of the ball. The weight of the ball is 13lb. 2oz.; that of the zinc and steel bars, nut, pendulum spring, and connecting screws, 2lb. 13½oz.; weighing in all nearly 16lb. In making up steel bars or rods for any compensation pendulum, it is proper to heat or blue them after they are finished, which will dispel whatever magnetism they may have acquired in working them up. The zinc bar of this pendulum, when brought near to the length of compensation, was about 21 inches. Taking the length of steel to be compensated by this at 61.75 inches, we may find what the compensation of the zinc should be, if the steel is rightly taken at 138.

The expansive ratio here is greater than 373, as given by Mr Smeaton; but is not equal to 420, as given by Mr Ward, from trials made with his pendulum.

The three zinc pendulums which have been described have each their peculiar properties. The zinc rods of the gridiron one are very troublesome to make; but they are more exposed to the air, or to changes of temperature, and are adjustable by means of the shortest traverse, and the sets of holes which are in them and the centre rod. When this pendulum is well executed, it is perhaps the best of the three. The one with the zinc tube is the strongest, the bearing on it being more firm and direct than in either of the other two; only it has no means for adjusting the compensation, unless by shortening the tube from time to time. According as the excess of its compensation is shown, something might be contrived to adjust it, without taking it from its place, but this would be too complicated; so that the shortening of the tube by degrees is rather the better way. Ward's is much more easily made than the other two. Those who use gridiron pendulums should have a half traverse, with three pins on it, similar to the shortest one in the pendulum, which will be found very convenient, when it is necessary, to shift for compensation. The half traverse and pins should be put into the holes, where the traverse in shifting is not to come. This will keep the pendulum rods in their places, and serve in the same way as the spare screw proposed for Ward's pendulum.

## CHAP. XI.

### *On the Wooden Pendulum Rod.*

The wooden pendulum rod does not come under the class of those which have just now been described; nor can it be supposed equal to any metallic compensation one. Having a good opinion of it, however, we put to trial one of them made of a very fine piece of straight-grained deal, that, for the purpose of seasoning, had been kept for five years near a parlour fire, which was almost constantly lighted throughout the whole year. The rod, when dressed up and fitted to the ball, and the pendulum spring put to it, was well varnished, so as to exclude any possibility of its being affected by damp. It was then applied to the clock, which, when regulated, went for about sixty days, during the months of June and July, without any apparent deviation from time; the very dry weather made the fixings for the clock case shrink a little. When these were again made more secure, the clock, during a trial of many months, could not be brought to give the same satisfaction. Whether this was owing to the wooden rod, or to what cause, we shall not at present pretend to determine. On this pendulum being taken away from the clock, a mercurial one was put in its place, having the same pendulum spring which was at the wooden rod, and every thing else being in the same state as before. The difference in the good going of the clock after this became truly astonishing, and may be considered as a striking proof of the great superiority of the one pendulum over the other.

It must here be observed, that, although the comparative trial by the same clock with the mercurial and wooden rod pendulums was in favour of the former, yet this clock and another were fixed on two planks, exactly the same as those described in the next chapter, and strongly fixed to a stone wall, opposite the brick wall where the other two clocks were, which gave rise to the discovery of their pendulums affecting each other's motions. Not being aware of this at the time of trial, the errors of the going of the clock, while the wooden rod pendulum was used, and the good going of it when the mercurial pendulum was applied, may have arisen from various causes, such as the elasticity of the upper plank, or the pendulums being of unequal length and weight. This much may positively be affirmed, that they were not going under such circumstances as to have a fair trial. We propose, however, to repeat the experiment with the wooden rod pendulum, applied to another clock, placed in a more insulated situation. An eminent American philosopher says, that deal has little or no longitudinal expansion, making it less than glass, as may be seen in the Table under the article Expansion, in this work.

In the Astronomical Observations published at Cambridge in 1769, by the late Reverend William Ludlam, Professor of Mathematics in that university, he has described a very neat and ingenious method of fitting up a pendulum with a wooden rod, constructed for the purpose of preventing any gyratory motion from taking place, as well as to have some resistance from the air. This was effected by having the pendulum ball of an equal mass round the centre of a round wooden rod, and by a thin flat hard steel crutch, to give impulse on the hardened ends of two screws put through the rod, which screws were to keep the flat crutch as near as possible in the plane or line of the diameter of the pendulum rod, or at right angles to the middle plane of the pendulum ball. This ball was nearly of the form of a cheese, or the middle frustum of a globe. For a more particular description of it, see Ludlam's *Observations*, page 81, Plate v.

From the description given of this pendulum by Mr Ludlam, it appears to be a very complete one, and several persons were on that account led to adopt it; but, from our experience, it was found to be much inferior to what might have been expected, and to possess, rather in a great degree, the very defect which Mr Ludlam wanted to avoid. The lateral coming and going of the pendulum rod by heat and moisture, causes the screws to come and go from the crutch, sometimes to clip it hard, and at other times to allow it to have more freedom between the ends or points of the screws than is proper. Finding that it had a strong tendency to gyratory motion when the clock was set a-going, (which however diminished some time after,) arising from the mass of the ball being carried out from the centre towards the edge, and from a thick rod passing through the centre, we thought of the following pendulum, which was afterwards put in execution, where the greater part of the mass of the ball is kept at the centre, and where the least quantity possible is towards the edge. A drawing of this pendulum is given in Plate CCCVII. Fig. 11. No. 1. and 2. The ball is of a lenticular form, 7 inches in diameter, thickness at the centre 2.5 inches, as seen at AA, AA, having a round wooden rod of about .6 of an inch in diameter, or thereabouts. The rod may be either round, flat, rectangular, or elliptical. This last is perhaps the best form; the transverse diameter being 1.5 inch, and the conjugate 0.5 of an inch. *a a*, *a a*, No. 1. are two small round steel wires, whose diameter is less than .2 of an inch, or say .175 of an inch, the length from pin to pin about 8.5 inches. They might be kept shorter, if care were taken to regulate the length of the pendulum by the going of the clock before fixing their length; in which case, they need not project more than .2 of an inch beyond the diameter of the ball. The centres of these wires are one inch apart, each passing through the ball at half an inch from the centre ; *b* 1, *b* 2, Nos. 1. and 2. are two pieces of brass, into which the ends of the steel wires are fitted and pinned fast ; their shape is represented in the drawing. In one of them *b* 1 is a socket in which the lower end of the rod is fixed; and in the lower one *b* 2, the regulating screw *d* passes freely through : $x, x$ are two brass nerrelled nuts, tapped to receive the screw *d*, which has also a conical nerrelled head fixed on it; the lower end of the screw serving as an index for the arcs of the pendulum's vibrations. On the upper end of the screw, the lower edge of the pendulum ball rests; and when moved up or down by the screw, the nuts $x, x$ are screwed against the brass piece *b* 2, in order to keep all fast.

The advantages which this pendulum possesses are very obvious. The whole of the momentum of the ball is so near the centre, that it maintains a very steady motion; and should any lengthening or shortening of the rod and steel wires take place, this will in some degree be compensated by the ball. Should they lengthen, the same cause will make the centre of the ball get upwards, the edge meanwhile resting on the end of the regulating screw, and *vice versa*. A piece of flat brass is fitted and pinned into the upper part of the rod CC, as seen in the drawing. Behind the rectangular hole made in this piece of brass to receive the crutch pin, a part of the wood is taken away, in order that the crutch with its pin may get as near as may be to the piece of brass. The piece of brass in which the lower end of the pendulum spring is, is fitted to the top of the rod, having two pins through it, to make it fast there. The upper end is fixed to a piece of brass, which goes on a steel arbor, having pivots to rest on a cock, and turn freely on it, so that the pendulum may take its plumb-line when hung on.

It has been observed by some cabinet-makers, that from drawers, whose sides and bottom were of cedar, there issued effluviæ, that inspissated the oil at the locks, and thickened it so much, that the locks became of no use till they were taken off and cleaned.

Pendulum rods have sometimes been made of cedar wood, and are objectionable on this account, as the oil at the pivot holes of the clock becomes thickened by it. Perhaps if pendulum rods of cedar were strongly varnished, this might deprive the wood of this inspissating quality.

It is of the utmost importance to have the pendulums of clocks well fixed at the point of their suspension ; and the cock to which they are suspended should, at the same time, be strong and firmly fixed to the wall of the place where the clock stands. This requires to be particularly attended to in turret clocks, and still more so in clocks intended for astronomical purposes. These last ought to be placed upon an iron bracket, strongly fixed to as massy a stone pier as can possibly be got into the place where the clock is to stand. We have had an instance of a pendulum which was so well fixed up, that there did not appear a possibility of its being made any firmer, or that the motion of the pendulum could in the least affect the cock and suspension, yet the arc of its vibration was a little increased, after having made considerable exertions to put farther home the screws, &c. concerned with the fixtures of the cock and the suspension of the pendulum. The arc of vibration did not exceed two degrees on each side of the point of rest, so that its motion, or centrifugal force, could not be very great at the point of suspension ; yet, small as this force was, it is clear that it was sufficiently great to affect the cock there, as this cause made the arc of vibration of less extent than when the suspension was afterwards more firmly fixed. We have suspended the pendulum on a strong brass cock, which was either rivetted or screwed to an iron plate. This iron plate was screwed firmly to the wall, the clock case being between the plate and the wall, and sometimes a notch was left in the pillar plate to receive the end of the brass cock, by which means the clock frame and the pendulum suspension were made to keep together as nearly as posible ; and when every thing here was so far adjusted, a strong screw with a square head was put through the cock, binding it and the pendulum top-piece firmly together. Another way is, to have two brass supports screwed on to a very strong seat board. These supports may be about one inch broad and half an inch thick, and in height about six inches, more or less, according to the height of the bending of the pendulum spring above the seat board. Each support has a strong and broad sole, and these soles have a stout steady pin to go into the seat board, which is screwed, from underneath the seat board, by a strong iron or steel screw fast to the upper side. The supports at the top incline a little towards each other, and a thick and broad piece of plate brass is screwed to them behind, so as to connect them firmly together. The upper ends of the supports are made level, and parallel with the soles and seat board. Across these ends is made a triangular notch, to receive the pivots of a piece of steel, to which the pendulum is suspended. By means of these pivots the pendulum turns, so as to hang freely in a vertical position. The distance between the ends of the brass supports at the top need not be more than two inches, while at the bottom the distance may be four inches, or not quite so much, the inclination being about ten degrees or so from the perpendicular. The piece of steel should not be less than half an inch thick at the middle, where it should be circular, and about three quarters of an inch broad. In the middle is a hole of about three-tenths of an inch in diameter : the two conical arbors are formed from the circular part, so as to be in a line with the diameter of the hole. The pivots of these arbors, which turn in the triangular notches, may be about three-twentieths of an inch thick. In the hole, which is three-tenths of an inch wide, is fitted a steel pivot, having a shoulder on the under side, which comes so far beyond the upper side as to admit a stout brass collet to be pinned on it, and against the upper flat side of the circular part, besides a sort of screw head on the end, with a slit in it, by which a screw-driver can turn it about, so that the pendulum ball may be made to stand in the plane in which it ought to swing. From the shoulder, below the circular part of the steel piece, to the lower end, may be an inch long. To this the pendulum spring is fixed. This, in some respects, is a very convenient mode of suspension, but we do not think it so strong and so firm as the other.

When the astronomical clock, formerly mentioned, which goes six weeks without winding up, was planned, care was taken to have the weight kept at as great a distance as possible from the pendulum ball, as we conceived that the attraction of the weight would disturb the vibrations of the pendulum. This idea, which appeared to us new, had occurred, we have been told, long before to several very able artists and amateurs, such as Graham, Harrison, Lord Macclesfield, Sir George Shuckburgh, Troughton, and others. In the course of our trials with the clock, the arc of the vibrations of the pendulum, when the weight came as far down as the ball, was observed to suffer a sensible diminution, and this was imputed to their mutual attraction. Upon mentioning this afterwards to one or two persons, supposed to be competent to judge in an affair of this kind, they entertained some doubts respecting this explanation of the fact, and thought it might probably arise from some motion communicated to the air by the swinging of the pendulum. Without making any experiments in order to examine the action of the air on the motion of the pendulum, an account of the fact, which was ascribed solely to attraction, was published in Nicholson's *Phil. Jour.* October 1812, vol. xxxiii. octavo series. Soon after this, Mr Ezekiel Walker of Lynn, in a paper published in the same Journal, endeavoured to shew, that the cause of this disturbance of the pendulum, (which he says had been known to him 30 years before,) arose from the motion of the air communicated by the weight to the pendulum, which it certainly did, as we soon afterwards found from one or two experiments, which did not occupy much time. In a paper of Mr Walker's, in Nicholson's *Phil. Jour.* for May 1802, vol. ii. octavo series, p. 76. entitled "Methods for diminishing the irregularities of Time-pieces, arising from differences in the arc of vibration of the Pendulum," he has assigned several causes for the changes that take place in the arcs of vibration, and proposed different methods to prevent them. But no notice whatever is taken of the motion communicated to the air by the pendulum. M. Berthoud mentions, in the first volume of his *Essai*, published in 1763, No. 642, that the air put in motion by the vibrations of the pendulum, acts against the weight of the clock, so as to set it in motion, and that this will in its turn gradually diminish the motion of the pendulum until it stops it altogether. This takes place more readily when the weight hangs by a single ball than when it is suspended upon a pulley. This fact, it must be confessed, had either been overlooked by us, or had entirely escaped our memory. Month clocks, from stopping frequently, have long been very troublesome to clockmakers, who no doubt assigned for it a different cause from the true one. In the old month clocks, the weights are very large and heavy, and the momentum of the pendulum very small, so that they were extremely liable to be stopped. But in clocks where the pendulum has even a considerable momentum, this agitation of the air will be sufficient to stop them altogether.

Having been called upon to examine a good astronomical regulator of Graham's, which had stopped, and which belonged to a nobleman in the neighbourhood of Edinburgh, we informed the man who was sent to put it in order, that he would find the weight opposite to the pendulum, which was actually found to be the case.

## CHAP. XII.

### *On the Sympathy or Mutual Action of the Pendulums of Clocks.*

It is now nearly a century since it was known that when two clocks are set a-going on the same shelf, they will disturb each other;—that the pendulum of the one will stop that of the other; and that the pendulum which was stopped will, after a while, resume its vibrations, and in its turn stop that of the other clock, as was observed by the late Mr John Ellicott. When two clocks are placed near one another, in cases very slightly fixed, or when they stand on the thin boards of a floor, it has been long known that they will affect a little the motions of each other's pendulum. Mr Ellicott observed, that two clocks resting against the same rail, which agreed to a second for several days, varied 1′ 36″ in 24 hours when separated. The slower having a longer pendulum, set the other in motion in $16\frac{1}{3}$ minutes, and stopped itself in $36\frac{2}{3}$ minutes. It never could have been supposed, however, that when very strong fixtures were made, it was possible for any thing of this kind to take place. About three years ago, in a room where astronomical clocks were placed under trial, two strong deal planks were firmly nailed to a tolerably stout brick wall or partition, the ends of the planks being jambed between the adjoining partitions. The planks were 6 feet long, 6 inches broad, and $1\frac{5}{8}$ths of an inch thick. One of them was placed behind the suspension, and the other behind the balls of the pendulums. The pendulums were suspended on strong massy cocks, partly of brass, and partly of iron, and, with the back of the cases, (one of which was of very hard oak,) were firmly screwed to the upper plank, and also to the lower one, the bottom of the cases being free and independent of the floor. Two clocks, whose pendulums were nearly of equal length and weight, and whose suspensions were distant from each other about two feet, kept so unaccountably close together for the greater part of twelve months, as to become a matter of considerable surprise. When the cold weather commenced in November, they made a small deviation from one another for a few days, and then resumed the same uniformity which they had before. An account of this was published in Mr Tilloch's Philosophical Magazine, where the observations of M. de Luc, which seem to have been a very near approach to the cause, were inserted by way of reply. The pendulum which was at one of the clocks, was of Ward's kind. On its being taken away, a gridiron one was put in its place; but with this, which was longer than Ward's, the clocks could never be brought to the same time as before. Their arcs of vibration continually varied, and no satisfactory going could be obtained from them, although we were well aware that they were competent to have given a very different performance. The gridiron pendulum clock was one of the best possible in its execution, and had one of the best recoiling 'scapements we have ever seen or made. The clock was taken from its case, to have a 'scapement of a different kind put in. In the meanwhile, the pendulum being left hanging in its place, was observed to be in motion, which was at first imputed to some shaking of the house. On being stopped, it got again into motion, and upon observing it narrowly, it was found not to be in such a direction as any shaking of the house could produce, swinging quite in time with the pendulum of the going clock, the two pendulums mutually receding and approaching each other. The cure was instantly obvious; and after the upper plank was sawed through between the clocks, the pendulum became in a little while dead and still. The arc in which it vibrated was about twelve minutes of a degree on each side of the point of rest, which was nearly about the greatest extent of variation in the arcs of the two pendulums. It would be imposible to make two clocks go closely together, in any other situation than the one which has been mentioned.

After the plank was cut through, the going clock was observed to be losing nearly at the rate of a second and a half a day; and if the clock which kept so long in unison with it had been tried under the same circumstances, it is probable that the rate would have been found to be fast. The rate they had for a period of eight or nine months or more, when they were close together, did not exceed two-tenths of a second fast a day, and this may have been a mean of the natural rate of each pendulum, if it may be so expressed; that is, suppose one clock was going slow 1.5 second per day, the other fast 1.7 second, there will be two-tenths of a second left for the acceleration of both, which seems to be the only way of explaining this phenomenon.

## CHAP. XIII.

### *On Turret Clocks.*

We have frequently seen turret clocks put up in places where no advantage was taken of the length of fall for the weights, which either did not descend through the whole height, or if they did, the ropes had a second rewinding, as it were, on the barrel. Hindley, who was certainly a man of genius, and whose turret clocks were perhaps unequalled in regard to their execution, though defective from no advantage being taken of the fall, made them all with barrels of a small diameter, and of such a length as to admit almost any number of turns, so that they could be placed in any situation, whether with propriety or not. We shall therefore lay down such rules, that a clockmaker may fit up a turret clock suited to any given fall for the weights.

Suppose that the height of fall for the weights is 25 feet, and that the clock is required to go eight days without being wound up, and with a single line to the weight, that is, with no pulley for the weight to hang on. We may allow 12 inches for what the weight will take. This reduces the length of fall to 24 feet; allowing 16 turns of the barrel to give 8 days going, and dividing the 24 feet of fall by 16, we shall have during the length of the rope 18 inches for one turn of the barrel. To find the diameter of the barrel, we say, as 355 for the circumference is to a diameter of 113, so is the circumference 18 inches of the barrel to its required diameter, which will be found to be 5.73 inches nearly. But this diameter would be too large, since the diameter of the rope must be taken into account; for the true diameter, or that which is necessary to run out the fall, must be taken at the centre of the rope when wound round the barrel. Allowing the diameter of the rope to be half an inch, then taking this from 5.73 inches, we shall have for the proper diameter of the barrel 5.23 inches. Having now obtained the diameter of the barrel, its length between the ends may easily be found. Sixteen turns of the barrel, the number wanted to produce eight days going, and a rope of half an inch in diameter, will require eight inches; but as the coils of the rope cannot lie quite close to each other, we may allow, for freedom, one inch and a quarter; consequently, if the barrel is made 9 25 inches in length between the ends, it will be sufficiently long. For the striking part, a rope of half an inch in diameter will be strong enough, and as one of a considerably smaller diameter, even one-half, would suit the going part, the going barrel may be made shorter. If the clock should be made to go by a double line and pulley, then the diameter of the barrels will require to be the double of 5.23 inches, or 10 46 inches. Or if the fall is only 13 or 14 feet, then the barrels of 5.23 inches in diameter would do, by means of a pulley. The diameter of the pulley will in part lessen the length of the fall, and in place of 12 inches we may now deduct 16 inches, or so, from the fall, on account of the length taken up by the weight and pulley; but this trifling circumstance requires little accommodation on the part of the clockmaker. Taking then the diameter of the barrel at 10 46 inches, in order to ascertain what diameter the barrel ends and the great wheel ought to have, the rope being half an inch in diameter, twice this added to the barrel's diameter will make it 11.46 inches, but, for the sake of even numbers, let it be taken at 11 inches and a half for the diameter of the plain barrel end; an additional inch, or 12.5 inches in diameter for the barrel ratchet end ought to do, unless when the barrel ratchet is put on the barrel end, and within its diameter, as is sometimes done, in order to have the great wheel of a less diameter than it otherwise would be, when the barrel ratchet end is done in the usual way. The centre of motion of the ratchet end click need not be more distant from the top of the ratchet than half an inch, or at most .6 of an inch, and .75 of an inch more than this for the breadth of the wheel rim, including the teeth. The semidiameter of the barrel ratchet end is 6.25 inches; to this being added .6 of an inch, and .75 of an inch, we shall have for the semidiameter of the great wheel 7.6 inches, or its diameter 15.2 inches. The diameter of the great wheel being thus obtained, we may get the circumference by saying, as 113 is to 355, so is 15.2 to the circumference required, which is found to be 47.75 inches; this divided by 240, the double of the number of the teeth proposed to be put into the great wheel of the going part, we have for the breadth of each tooth and each space 0.199 of an inch, or nearly .2 of an inch. It is perhaps advisable to have the space a very small degree less than what is here given; the teeth will then be somewhat more than .2 of an inch in breadth. Taking small temporary segments of thin brass, having the same radius as the wheel, and cutting them from the proposed number on the cutting engine, will lead us to form an idea of the strength that the teeth may have. Indeed this, and calculation together, ought to go hand in hand, and is the way that any ingenious clockmaker ought to adopt, if his object is to have the best possible contrivance in the construction of any piece of work in which he may be engaged.

If it is proposed to have the pendulum of such a length as to swing 30 beats in a minute, the swing-wheel having 30 teeth, and the pinions 10 each; then the numbers for the teeth of the second and third wheels will be 60 and 50, and the length of the pendulum 156.8 inches; where twenty feet or upwards, for length of fall and strength of clock can be obtained, a shorter pendulum than this should never be adopted. The diameter of the second wheel may be made half of that of the great wheel, or even a little less; however, we may safely take it at the half, viz. 7.6 inches, as it is to be cut into half the number of teeth, and being considerably thinner than the great wheel, the teeth will, notwithstanding this, be sufficiently strong for the force exerted on them. The third wheel having 50 teeth, and the force exerted on them being considerably less than that on the second wheel, we may obtain the diameter of the third wheel, by first taking the proportion of 60 to 50, and then making the diameter somewhat less than the first proportion would give, because, were the teeth cut on this diameter as given, they would be as strong as those of the second wheel. We then say, as 60 teeth is to its diameter of 7.6 inches, so is 50 teeth to the diameter required, which is found to be six inches. Taking six inches in the compasses, and applying them to the legs of any sector that has a line of equal parts, both legs of the sector being extended till the points of the compasses fall exactly on 50, set the compasses to the number 45, which will give a distance equal to the diameter of the third wheel. This will be found to be 5.5 inches nearly, and if the spring wheel is made five inches in diameter, it will do very well.

The barrels both in the going and striking parts being made equal in diameter, and each performing a revolution in 12 hours, we now proceed to make out proper numbers for the striking part, and diameters for the great wheel, the pin wheel, and the tumbler wheel; this last we shall also make use of as a fly wheel. The diameter of the barrels being equal, the great wheels may also be equal, and the diameter of the striking great wheel will be 15.2 inches.

The number of blows which the hammer must make in 12 hours can be obtained by a very simple rule. The first blow 1 being added to the last blow 12, will make 13, and 13 multiplied by 6, half of the number 12, will give 78 for the number of blows required during one revolution of the great wheel and barrel. The great wheel of the striking part will require to have stronger teeth than that of the great wheel of the going part, because there is a stronger rope and a heavier weight applied against them, in order to raise as much weight of hammer as may be, so as to bring a sufficient sound from the clock bell. The pin wheel pinion being 10, and the wheel 64, having eight lifting pins in it for the hammer tail, the number of teeth in the great wheel which will be necessary, so that one turn of it may produce 78 blows, may be either 98 or 100.

Suppose we take 98 for the number of teeth; 98 divided by 10, the number in the pin wheel pinion, the quotient will be 9.8, which, multiplied by 8, the number of pins in the pin wheel, will give 78.4 for the number of blows for one revolution of the great wheel. If the great wheel should have 100 teeth, this, divided by 10, will give 10, and this again multiplied by 8, will give 80 for the number of blows during one turn of the barrel; either of these numbers for the teeth of the striking great wheel would do very well. If we take 98, and as the pin wheel is to have 64 teeth, we may find a proper diameter for it, so that the teeth may be nearly about the same size as those of the great wheel. Say as 98, the number of teeth in the great wheel, is to 15.2 inches, its diameter, so is 64, the number of teeth required in the pin wheel, to a diameter required for it, which will be found to be 9.9 inches.

The pin wheel, having 64 teeth, and 8 lifting pins in it, the tumbler wheel pinion, which makes one revolution for every blow of the hammer, must have 8 teeth or leaves in it. The diameter of the tumbler wheel must be considerably smaller than that of the pin wheel, and this will depend on the number of teeth it ought to have, on the number of leaves in the fly pinion, and on the number of the revolutions which the fly pinion is to make for every blow of the hammer. The less the number of revolutions given to the fly pinion during one blow of the hammer, the less will the striking part be under the influence of oil. But few turns in the fly require it to be considerably extended in the wings or vanes, and this demands some ingenuity and address in the clockmaker to carry them out, so that they shall be conveniently clear of every part of the clock. When the arms of the fly are extended, the wings or vanes can be considerably diminished in surface; and a little weight may be given them, so that when once the fly is set in motion it will not easily stop. The construction of the fly, and fly pinion, has hitherto been injudicious. The flies commonly applied to turret clocks were too heavy, the wings or vanes were too broad, they made too many revolutions, and the fly pinion was not so properly sized as it might be; for it must be considered that it acts not merely as being driven, but it must sometimes act as a leader. For although the tumbler wheel, or fly wheel, which turns the fly pinion, acts as a driver, yet, from the nature and application of the fly pinion and fly to regulate the velocity of the striking, the fly pinion, from the acceleration which it will acquire, must sometimes act as a leader, so that the size of the fly pinion ought to be a mean between the size of a leader and that of being driven. If the pinion is made too large, or the size of a leader, the wheel teeth in driving it would be apt to butt on the pinion, and if made too nicely, as it were, to be driven, it could hardly ever act as a leader, as here the pinion would butt on the wheel teeth; this then is the reason of keeping it to the mean size of the two, which will be found to have a good effect. The arms of the fly may be about twenty-six inches.

The number of the revolutions of the fly pinion for one blow of the hammer is arbitrary; in some clocks the fly may make twenty revolutions, in some more and in some less. When the revolutions are few, and the acceleration of the fly fit to carry forward in a small degree the striking, it may appear to strike faster towards the end of a long hour, but it will require a nice ear to perceive it. We have made the fly pinion to have only four turns for one blow of the hammer, which answered extremely well, so that the tumbler wheel will require 40 teeth, supposing the fly pinion to have 10. If we take the ratio of the pin wheel of 64 to its diameter 9.9 inches, then the tumbler wheel of 40 would have its diameter 6.25 inches, the teeth would then be of the same size or strength with those of the pin wheel; but this is not requisite, as they will bear to be considerably diminished in size, and if the diameter of the tumbler wheel is nearly 5.5 inches, the teeth will be sufficiently strong. In the striking part there is no fly wheel and pinion.

The locking of the striking part of turret clocks requires safe and good mechanism. That which Hindley used is very ingenious, and was adopted in the clock made for St Andrew's Church in Edinburgh; yet, from foulness of oil or dirt, it is liable to misgive, and in attempting to rectify it, the ignorance or carelessness of workmen is apt to increase the evil. The nicety of this locking lies in the pins of the count-wheel, whose office is to raise up the locking-lifter, and pass it at the same time. The locking which is here proposed, is by means of two pins or detents on the fly pinion arbor, one of which is for locking on, and the other is a detainer while the striking is on warning. In this motion work, we have a rack, having teeth on the inside as well as on the outside; the tumbler raises the rack by means of the inside teeth, the rack-catch acts by those on the outside, and is concentric with the hour-lifting arm, or that which discharges the striking; but both move freely and independently of each other. When the rack is on the lifting of the last tooth by the tumbler, a pin which is in the rack carries forward the end of a lever or arm. Concentric with this arm, and fixed with it, another arm presents itself (at the same instant when the pin in the rack has carried the arm forward) to a pin or detent on the fly pinion arbor, and here the striking is locked. The pin in the minute wheel, on raising up the hour lifting arm, raises at the same time the rack catch, and consequently allows the rack to fall, and the pin from the fly pinion arbor, which before this was locked, gets disengaged; and here the striking would go improperly on, but another arm, which is connected with the hour-lifting arm, presents itself to the other detent on the fly pinion arbor, and detains it till such time as the lifting arm drops off from the pin in the minute wheel, and then the striking being at liberty goes on, and is again locked when the pin in the rack is made to move one of the locking arms forward. This locking is sure and safe, and very easily executed.

The pins of the pin wheel ought to be pretty stout, and one half of their diameters should be cut away, so as to allow the hammer tail to drop off freely, causing as little loss as possible of the force of the weight. Some have made very slender pins, and strengthened them by their opposite ends being fixed in a small circular rim or ring over them; but small pins are apt to tear and wear away the acting part of the hammer tail. The hammer tail may be so constructed, that it begins to raise the hammer head when the lever by which it acts is at its maximum length, the head having then a more horizontal position than when it is afterwards raised up. The principle laid down here of the striking, &c. was adopted and put in execution in the two turret clocks which were made by Mr Reid for the royal burgh of Annan, and which are not equalled by any turret clocks in the island. The frame of these clocks is so constructed, and the wheels so disposed, that any wheel can be separately lifted out of the frame, without either taking it to pieces, or removing any of the other wheels.

The diameters of the wheels and the length of the barrels being determined, we may thence fix upon the length and breadth of the clock frame, which is proposed to be rectangular, and the wheels lying all nearly in a horizontal position, making it of such dimensions as not to pinch any part of the work, nor yet to have a superabundance of room. Beginning, then, with the going part:—The great wheel being 15.2 inches in diameter, and having 120 teeth, and the pinion which it drives 10, we know that the distance of their centres will be 8.081, or 8.1 inches nearly. We also know, that in the case of the second wheel of 7.6 inches in diameter, and 60 teeth, driving the third wheel pinion of 10, the distance of their centres must be 4.273 inches. In like manner we get the distance of the centres of the third wheel, and swing wheel. The diameter of the third wheel is 5.500 inches; the swing wheel pinion being 10, we have for the distance of their centres, 3.158 inches. By taking these distances, and adding them together, with the semi-diameters of the great and swing wheels, we shall have the space that would be required to contain the going part.

| | Inches. |
|---|---|
| From the centre of the great wheel to that of the second wheel, . . . . . . . | 8 081 |
| From the centre of the second wheel to that of the third wheel, . . . . . . . | 4.273 |
| From the centre of the third wheel to that of the swing wheel, . . . . . . . | 3 158 |
| The semi-diameter of the swing-wheel, . . | 2.5 |
| The semi-diameter of the great wheel, . . | 7.6 |
| Inches, | 25.612 |

So that it requires 2 feet, 1 inch, 6 tenths, and a very little more, to contain the going part.

By proceeding in the same manner, we shall find the distance of the centres of the wheels in the striking parts to be as follows:

| | Inches. |
|---|---|
| From the centre of the great wheel to that of the pin wheel, . . . . . . . | 8.1875 |
| From the centre of the pin wheel to that of the tumbler wheel, . . . . . . | 5.6815 |
| From the centre of the tumbler wheel to that of the fly pinion, . . . . . . . | 3 2544 |
| Semi-diameter of tumbler wheel, | 2.75 |
| Ditto of the great wheel, . . . . | 7.6 |
| | 27 4734 |
| To which add the space required for the going part, . . . . . . . . | 25.612 |
| Gives for inches, | 53.0854 |

The length, then, required to contain the going and striking parts, is about 4 feet 5 inches, being the inside length of the frame.

The width inside of the frame depends on the length of the barrels, the thickness of the ends, and of the great wheels, &c. The striking barrel being the longest, we must take the length given for it, which was determined to be 9.25 inches between the ends. Allow one quarter of an inch or so for the thickness of the plain end, and half an inch for that of the ratchet end, and about 3-4ths of an inch or so for the thickness of the great wheel, these being 1.5 inches, which, added to the length of the barrel, makes 10.75 inches. The pin wheel is supposed to run behind the great wheel, having a proper freedom between them, the pins for lifting the hammer tail being on the opposite side of the pin wheel, and the plain barrel end having a sufficient freedom of the front bar of the clock frame. We shall call this freedom about .3 of an inch, and as much for the freedom of the pin wheel and great wheel; the thickness of the pin wheel about .4 of an inch, or a very little more; the height of the pins from the surface of the pin wheel about .6 or .7 of an inch.

| | Inches. |
|---|---|
| The length of the barrel, with its additions, was, | 10 75 |
| Freedom of plain barrel end, . . . . . | .3 |
| Ditto of great and pin wheels, . . . . | .3 |
| Thickness of pin wheel, . . . . . . | .45 |
| Height of pin wheel pins . . . . . | .7 |
| And take the distance of their tops from the side bar of the frame at . . . . . . | 1.25 |
| Inches, | 19.75 |

By this it appears, that the distance between the bars of the frame inside will require to be 13.75 inches. The side bars, one on each side of the frame, are of forged iron, about four inches in breadth, and .4 of an inch thick, having at the ends a sort of thickness left there, so as to form a shoulder, and beyond the shoulders are tenons, not quite so thick nor so broad as the bars themselves; these tenons, about 4.5 or 5 inches long, are fitted into a rectangular hole, in the cast iron part of the frame, which compose the ends of it. The ends of the tenons are sometimes formed into two screws, each having nuts to bind them against the shoulders, and with the cast iron ends: or having sometimes slits in them to receive a strong iron wedge to bind the shoulders; either of them will do very well. The length from shoulder to shoulder of the side bars need not be quite so much as that which has been allowed for containing the going and striking wheels. If this length is 4 feet 4 inches, it will be sufficient; the space given by the cast-iron frame ends will more than compensate what has been deducted from the calculated length. The cast-iron ends are composed of two sorts of pillars, connected by a rectangular bar, near 5 inches broad, and about half an inch thick; the length of the rectangular bar such as to allow the side bars, when the tenons are into the square part of the pillars, and in the rectangular hole which is made there to receive the tenons, that the inside of the side bars shall be only distant from one another 13.75 inches. The middle part of the pillars is a square of about 3 inches, and 6 inches long; the upper and lower ends of the pillars are turned into such a figure or shape, as the taste or fancy of the artist may suggest. The middle of the rectangular hole which receives the tenons may be distant from the lower end of the pillar about 12 inches; the top of the upper end may be equally distant. This frame, if constructed in the manner which has been directed, will be found to be strong, firm, and stiff, and very handy and convenient, while going about the making of the clock. Should it be thought that the side bars from their length may yield a little, a foot can easily be attached to each, near to the middle of the bar, or any other convenient place.

Nothing about a turret clock requires more skill and ingenuity, than to construct properly the wheel work for setting off and carrying the hands to the different dials, more especially if there are more than two. The wheels for this purpose should be as few in number as possible, having the least allowable shake between the teeth, and a sufficiency of freedom in the end shakes of the arbors, and in the conducting rods. Turret clocks, with four dials and hour and minute hands to each, were formerly but very seldom made. The town clock of Edinburgh has four dials, with hour and minute hands to each, which we put to it in the year 1795.. It is an excellent specimen of this sort of mechanism. Hooke's joint has been found very useful in the conducting rods for the dial work; but where any oblique direction is given to the rods, Hooke's joint will make the hand rather to go irregular, making the hand more forward at one part, and more behind at another, than it ought to be. In large turret clocks, which have minute and hour hands, the wind and weather give a very severe trial to the dial-work and wheels, and such clocks are in general very much exposed to such trials. In the clock which we have been planning, the second wheel pinion making one revolution in an hour, is that which must conduct the dial work. Let that pivot of it which comes through the fore side bar be left pretty thick, and prolonged three or four inches beyond the bar outside. Two ways have been adopted, to prevent the hands from changing their place by any force or violence, arising from winds or any other cause. One of them consisted of a pretty stiff or strong circular spring, keyed on behind the minute wheel; the other consisted in putting on the minute wheel arbor a wheel, with square or unrounded off teeth, into which teeth a click from the conducting wheel passed into the space or spaces. We propose to adopt the first of these two methods at present. On the thick pivot of the second wheel pinion, outside of the front bar, let a square be made of .3 of an inch long; on this let the square socket of the circular spring be well fitted, and the side or angle marked to correspond, so as to know at all times that which it has been originally fitted to: this spring may either be of steel or brass, and the diameter equal to that of the minute wheel less by the teeth. From the square part of the pivot let this arbor be turned down, but hardly more than what is necessary to form an arbor nearly cylindrical; the square sides must not be completely turned out, otherwise this might render the arbor too small. The diameter of the minute wheel may be about 4.5 inches, and cut into 40 teeth; on the same socket with the minute wheel, let there be a bevelled wheel of 5.5 inches in diameter, and having 50 teeth, the distance of the back of the bevelled wheel from the nearest side of the minute wheel being about half an inch, or .6 of an inch. This space is to allow the hour lifting arm to come in between them, so that the lifting pin in the minute wheel may freely get hold of it; the whole length or height of the socket may be about 3, or 3.5 inches, and turns on the cylindrical part, or arbor, of the prolonged pivot. Two other bevelled wheels of the same number and diameter as the other are cocked on the front bar, so as to pitch with the first; their arbors are disposed horizontally, and at right angles to the socket of the first bevelled wheel, so that they may be connected with the dial wheels on the two opposite dials, whose wheel and minute hands they will conduct. Over the first bevelled wheel, and pretty near the inside of it, is placed a round brass dial, having minute divisions and figures on it. A minute hand on the socket, having a collet against them pinned by the end of the arbor, will keep the minute wheel tight on the arbor by means of the spring behind it. When there are four dials, then, in place of the two wheels, with their arbors horizontally placed, let there be one arbor placed perpendicularly, on which are fixed two bevelled wheels, the upper one of which pitches with the first bevelled wheel; the lower one, whose lower pivot or arbor may be connected with that of another, which carries a bevelled wheel, turning four others, all of them in the same frame: The four wheels, if properly placed, will turn the four minute arbors at the dials all in their proper course or direction. This frame will require to be placed a little below that of the main frame of the clock. It is seldom that four dials are wanted, and in most instances the two opposite generally suffice. To lead the snail wheel, or what is generally though improperly called the hour wheel, let another flat minute wheel of the same number of teeth and diameter as the first be pitched with it, and whose arbor goes through the main frame; and near the edge of the going great wheel, a little below, on the left hand side, a cock on the fore bar receives the wheel pivot, and the arbor is free on the fore bar: The other pivot, which is left pretty thick, turns in the back bar; on the end of this pivot, which is prolonged a little way beyond the bar, is formed a lanthorn pinion of 4 or 6, or such a number as may suit the number of teeth in the snail wheel; or a pinion of a proper number having a prong to it, may be twisted in a hole made in the arbor to fit and receive it. A lanthorn pinion of four will lead about the snail wheel and snail, having a common socket; the wheel having 48 teeth and 7 inches in diameter, and turning on a stud in the back bar; the rack is also on a stud here. The pivot required to have a lanthorn pinion formed on the end of it, for a wheel of 48 teeth and 7 inches diameter, would be rather too thick; so that by keeping the pivot of a moderate size, or sufficiently thick to have a hole in it to receive the prong of a pinion of 6, and the snail wheel 72, may be a better way than that which we first proposed. The hour lifting arm and the detaining one may be formed or not from one and the same piece, and fixed on an arbor which lies above the great wheel, whose pivots must run in cocks attached to the main frame; cocks are also required for the hammer, the verge, and the pendulum. The length of the pendulum which we have proposed for this clock, may be thought by some rather inconveniently long, which is a matter that can very easily be got the better of, by assuming any other lengths, say 6, 7, or 8 feet: either of these lengths will have perhaps dominion enough over the clock; but these will require other sets of numbers for the second and third wheels, allowing the pinions to remain 10 each, and the swing wheel to have 30 teeth. The second wheel having 75 teeth, the third wheel 60, the pinions 10 each, and the swing wheel 30, the vibrations in a minute are 45, and length of pendulum required is 5 feet 9.7 inches. If the third wheel of this set is made 70, all others remaining the same, the vibrations in a minute will be 42, and the length of the pendulum 6 feet 8 inches: 40 vibrations in a minute would require the wheels to be too disproportionate in numbers, unless we were to make one of the pinions 12 in place of 10; the wheels in this case would be 75 and 64. In the other they would have been 80 and 50. The length of pendulum is 7 feet 4.2 inches; the vibrations in a minute 38; the pinions 10 each, and the swing wheel 30. The wheels are 75 and 64, the length of pendulum 8 feet, 1.73 inches. Wheels 80, 72, and 30, and pinions of 12, will give 40 vibrations in a minute.

. It is certainly not requisite to give any more examples of constructing turret clocks. The one which has been given is sufficient to enable any intelligent artist to proceed in this way, whether with clocks going eight days, or with those which require daily winding up. There are often great objections made against the trouble of daily winding up a turret clock; but when this trouble can be submitted to, a clock of this sort is decidedly preferable to those which go eight days. Turret clocks which strike quarters are sometimes made, some of which are done by a quarter rack and snail, and others by a count wheel. For the description of a thirty hour clock of this kind, put up in the town-house of Paris in the year 1782, we refer to Berthoud's *Histoire de la Mesure du Temps par les Horloges.* This is perhaps one of the finest public clocks in Europe. It was constructed with much care and expense, and is the only one which has enamelled dials, one of which is above 9 feet in diameter.

Although not in its proper place, we may here remark, that where four sets of dials and dial work are required, it would hardly be safe to trust them to a young tight collet behind the minute wheel. We would therefore propose, that the pivot of the second wheel pinion be squared down, and a little longer beyond the fore bar than what was proposed for the square of the spring; this is for the particular reason of getting easily at a bolt pin when at any time setting the hands. On this square of the pinion let the squared socket of a plain wheel be very well fitted. This wheel is about 3.6 inches in diameter, and in thickness about one-fourth of an inch. The minute wheel must have a sink in it, so as to receive the plain wheel, but the sink must be more extended in diameter, to admit a skeleton sort of a rim of a wheel with forty teeth cut inside of it. This rim must fit well the inside of the sink in the minute wheel, and be fixed to it, either by soft solder, or some other means. The minute wheel, in this case of the sink in it, will require to be thicker than in the case of the spring collet. A bolt may be lodged under a dovetail slit made in the plain wheel; in this slit, and lying close to the sink, the bolt can be made to move out or in to the inside teeth on the minute wheel; on the end opposite that of the locking end of the bolt is fixed a stout round pin or knob, for the finger to pull out when occasionally setting the hands; this pin serves also for a stout spring to push the bolt into its place between the inside teeth.

In fitting up the dial work immediately behind the dials, it may be recommended to adopt that which was contrived and put in practice in the different dial works of St Andrew's church clock; on the minute arbor, just by the lower end of the hour wheel socket, is a loose steel washer, which lies close to the fore-plate of the dial work frame; and should the wind press the hour hand and hour wheel socket down, it affects no other part, but only presses the washer against the plate. Inside of the dial work frame, and on the minute arbor, are washers, to prevent any binding on the ends of the hour-wheel socket.

In the town clock at Paris, the revolutions of the fly striking the hour are eight, for every blow of the hammer; the fly of the quarter part makes four revolutions for every quarter hammer blow, there being ten lifting pins on each side of the great wheel, making 20 lifts, the amount of the quarter blows in an hour. The wings or vanes of the flies in this clock are pretty broad and long, and can be set to take more or less hold of the air. The fly of Hindley's clock in the Orphan Hospital makes 4.57 turns for every blow of the hammer; but, from the imperfect construction of the clock, no adequate weight of hammer can be raised, and hence a sufficiency of sound cannot be obtained from the bell. It has been said, that the weight of the hammer for this purpose should be 5 pounds weight for every 100 pounds in the bell. Turret clocks in general must either have their bells too large for this proportion, or the clocks have not been made to raise a heavy enough hammer. The arm of the hammer, when at rest, should hardly make an angle of elevation above 20 degrees, or 24 at most; and in order to get as much mass of matter in the hammer head, the tail by which it is raised should be pretty long, and give a rise from the bell as little as possible. But this distance of rise from the bell must depend, among other things, on the length of the arm, and on the angle or length raised by the pin wheel and hammer tail.

It was formerly proposed to fix on the fore bar the small dial, to which the minute hand is set at, when setting those of the principal dials; but it matters not whether a dial is fixed and the minute hand is moveable, or the minute hand is fixed and the dial moveable. Suppose that, by means of three small and short brass pillars, fixed inside of the bevelled wheel, we now screw on the tops of them a light round dial, having the minute divisions and figures on it, and the minute index fixed to the fore bar, we can here make the bevelled wheel be turned about, till the minute index points to the proper minute. This mode will, besides, allow us to have more conveniently three sets of dial work, that is, two by the bevelled wheels, whose arbors are laid horizontal, and the third by connecting it with the socket of the first or front bevelled wheel.

Where turret clocks are of a large size, and have very heavy weights applied to the barrels, they require much force and strength to wind them up. In order to remedy this, an apparatus of much the same nature as that which is commonly applied to cranes has been used. This consists of a wheel, with rather strong and coarse teeth, fixed on the barrel end, opposite to that where the great wheel is. A pinion of any number, on whose arbor is a square to receive the winding up key, is attached to the clock frame, by means of a cock, &c. so as to pitch with the wheel on the barrel end; and by this means, a considerable weight can be raised with ease, requiring much less exertion, but more time, than when the winding up was performed by the barrel arbor. The clock in the town-house of Paris is wound up in this manner, which is represented in the drawing of Vick's clock, Plate CCC. Fig. 1. The size of the wheels and strength of teeth may be regulated according to the weight to be wound up. The weight of the going part is in all cases light, when compared with that which is necessary for the striking part, in most of these clocks. Besides the advantage of winding up a heavy weight with ease, this method has another, which is, that the barrel arbor pivots can be used, either in conducting the hands, discharging the quarter and striking parts, or turning count wheels, &c. The old way of the division of the hours striking by the count wheels and locking plate, and locking on the hoop wheel, does not yield in ingenuity to any thing which has been since introduced in its place by modern clockmakers. The only great objection to the old way was, the trouble of making the clock strike a round of eleven hours, when the striking of the hour corresponding with the hands took place from any accidental discharge. It may not be out of its place to observe here, that the application of the cord or rope for the weight should be on that side of the barrel which lies next to the pinion into which the great wheel acts, especially in turret clocks, as this relieves the barrel pivots of a great degree of friction, which they would otherwise undergo, were the course of the rope and weight on the opposite side.

## CHAP. XIV.

### *On the Method of fitting up Astronomical Clocks.*

Although the example of calculation which we have given for the different parts of a turret clock, is applicable to any clock; yet, in order to make the calculation more familiar and easy, we shall apply it to an astronomical clock, intended to go 32 days without winding up, performing the computation in the most rigid manner, as these clocks ought to be made as perfect as possible in all their parts.

From the inside bottom of the intended case to the under side of the seat board is supposed to be 4 feet 10.7 inches, the seat board one inch thick, and the distance from the upper side of it to the centre of the dial 3.125 inches, or $3\frac{1}{8}$ inches. From these, to obtain a proper diameter for the barrel, which is to have sixteen turns on it, we propose that the length taken up by the pulley and weight shall not exceed 6 inches, and that the weight shall be about 10lb. or perhaps even less. Four feet 10.7 inches diminished by 6 inches will be 4 feet 4.7 inches, and this doubled will be 8 feet 9.4 inches; which divided by 16, the number of turns proposed for the barrel, we shall have 1054 tenths of inches, which, divided by 16, will give 65.875 tenths for one turn round the barrel. From this, to find the diameter of the barrel, say as 355 is to 113, so is 65.875 to the diameter required, which will be found to be 2.0968 inches. The diameter given here for the barrel must be lessened by a diameter of the gut. The diameter of the gut, which we had 24 years at a month clock, and which carried a weight of 24lbs. was .045 of an inch; it might have even supported it much longer, but a different weight was afterwards hung on. It is very thick gut at .080 of an inch, and .060 of an inch is about the diameter of common sized gut, which we shall take for our estimate in the diameter of the barrel; then 2.0968 inches *minus* .060 of an inch, will give for the true diameter of the barrel 2 0368 inches. The diameter might be kept even a little larger than this, since the cutting of the screw upon the barrel for the gut to ride in will lessen it a little. The depth of the screw cannot be much more or less than .020 of an inch, at which we shall take it; 2.0368 + 0.20 will then make the diameter of the barrel 2.0568 inches. It is more than 40 years ago since we proposed that the trade in general should adopt for all their work gages, inches and the lowest subdivisions of an inch. Had this been done, it would have made all the communications between the different branches of the art extremely simple and easy; and yet, however simple this may appear, it has never been done. It must be observed, that every branch, such as movement-maker, enameller, glass-maker, spring-maker, verge-maker, &c. have all their own gages, no one of which corresponds with that of his neighbour's, and all these gages have numbers applied to them. On what these numbers are founded, it would puzzle very much both the makers and owners of the gages to tell.

To get the length of the barrel between the ends, let us take the diameter of the gut at .080 of an inch, in order to allow freedom between the turns on winding round the barrel. This .080 multiplied by 16, the number of turns proposed, will give 1 28 inch, or very near 1 inch and $\frac{3}{10}$ths of an inch, for the length of the barrel between the ends. The barrel, or great wheel, making a revolution in 48 hours, we must see what the number of teeth for it, and the second wheel pinion which it drives, ought to be, and likewise the number of teeth for the second wheel, and that of the centre pinion, so that this last shall make 48 turns for one of the great wheel. Let us assume 24 for the number of the second wheel pinion, and 20 for that of the centre pinion. If we take 6 times 24 for the number of the great wheel teeth, and 8 times 20 for the number of teeth in the second wheel, then the centre pinion will be turned 48 times round for once of the great wheel, as $6\times8=48$. Having assumed the pinions to be 24 and 20, these multiplied into one another, and the product multiplied by 48, the last product will be such a number, as when divided by a number for one wheel, the quotient will be a number for another wheel, $24\times20=480\times48=23040$, which divided by 144, the number for one wheel, the quotient will be 160 for the number of teeth of the other wheel. Or if we take 25 for the number of the second wheel pinion, and 20 for the other, these multiplied together, and the product again by 48, will give such a number, as when divided by 150, the number for one wheel, the quotient will be 160 for the number of the other wheel, $25\times20=500\times48=24000\div150=160$. The numbers for the teeth of these wheels may be obtained in the same way which we make use of to find the numbers of the teeth of the wheels for clock and watch movements. If we take 26 for the second wheel pinion, and 20 for the centre pinion, and multiply them into one another, and if the product is again multiplied by 48, the number of turns of the centre pinion for one of the great wheel, we shall have a number, which being subdivided till there is no remainder, its multiples will form such sets of numbers as may be given for the teeth of the two wheels. Thus $26\times20=520\times48=24960$, the multiples of which will be seven 2's, one 3, one 5, and 13, which give the numbers 156 and 160 for the wheels. For the subject of our astronomical clock, we shall adopt the number 144 for the great wheel, and 160 for the second wheel, and its pinion 24, and 20 for the centre wheel. The object is to have as high numbered wheels and pinions as can be conveniently got in. The diameter of the great wheel is assumed to be such, as will allow the teeth proposed for it to have strength enough to bear the exertion put upon them, which we shall take at 3.520, and for that of the second wheel 3 300. In other words, these are 3.5 inches, and .020 parts more of an inch, and 3.3 inches for the other. The pinions for the third and swing wheels are to be 16 each, the number of teeth for the centre wheel 128, and for the third wheel 120. For the sake of saving trouble to those who may be inclined to make such a clock, we shall give the diameters of the wheels and pinions, and the distance of their centres.

| | Teeth. | Diameter. | Distance of Centre. | Pinion. | Diameter. |
|---|---|---|---|---|---|
| The great wheel . . | 144 | 3520 | 2021.7 | 24 | 614 |
| Second wheel . . . | 160 | 3300 | 1830 | 20 | 437.2 |
| Centre wheel . . . | 128 | 2600 | 1437.2 | 16 | 349.3 |
| Third wheel . . . . | 120 | 2300 | 1280 | 16 | 329 |
| Swing wheel . . . | 30 | 2000 | | | |
| Wheel concentric with the second ditto . | 20 | 743.6 | 1322 | | |
| Wheel carrying the hour hand . . . | 60 | 2032.5 | | | |

The wheel of 20 is concentric with the second wheel, which, making three revolutions in 24 hours, carries the hour-hand wheel of 60 once round in that time. The hour circle will have the 24 hours marked on it, that is, from 1 to 24, being intended for a sidereal time clock. There is no other dial-work than the wheels of 20 and 60, which will require to have the hour-hand turned about by itself,* when at any time the clock is set by the minute hand. From the centre of the dial to the centre of the hours and seconds circles, is 2.5 inches to each. The centre of the great wheel is on a line below the centre of the dial about

* This cannot be considered as inconvenient by those who wish to have the most perfect mechanism for the dial-work.

1 inch, and to the left of the perpendicular line, in the centre of the dial, 2.9 inches. The centre of the third wheel is also to the left of this line, a little more than half an inch, say .519 of an inch. The 'scapement we would propose to be the same as those which we have made to astronomical clocks, after the principle of that of Mudge's time-keepers; only the pallets might be made longer, and the springs of course a little stronger. The angle of 'scapement might be reduced to 15 minutes on each side of the point of rest, and yet the pendulum may be made to vibrate about 1.5 degrees on each side. The unlocking here would be as near the lowest point as possible, or when the pendulum had its maximum force.

## CHAP. XV.

### *On Chimes and Bells.*

Chime, in its general meaning, is applied to the sounding of bells, such as change-ringing by church bells, or the striking quarters of the hour by a clock on two or more bells, or to tunes played by a clock on a series of nine, twelve, or sixteen bells, tuned to their respective notes on the scale. Clocks that play tunes on bells are called musical clocks; when hour quarters are chimed or struck by the clock itself, for example, on six or on eight bells in octave, it is called a quarter clock, and sometimes a chime clock; and when the quarters are struck by a string being pulled, it is called a pull quarter or a repeating clock, whether the quarters are struck on six or eight bells, or whether they are given by a double blow on the hour-bell, as in the repeating watch. A time piece, or going part, and having no hour striking part, but having a repeating part, is by some called a silent pull.

Various ways may be adopted for pricking tunes on the music barrels of clocks. The earlier mode of doing this was by taking a piece of writing paper of such a size as to cover exactly the surface of the barrel, and in a direction perpendicular to the axis of the barrel, to draw as many lines parallel to one another as there were notes in the tune to be laid down on the barrel, the lines being equidistant, and corresponding perfectly with the hammer tails as they stood in the hammer frame. They were marked at each end with the letters or notes they were to represent in the gamut or scale of music; and, according to the number of bars in the tune, as many spaces were made by lines drawn equidistant and parallel to each other, intersecting the others at right angles. The junction of the ends of the paper, when applied round the barrel, represented one of these bar lines. The length or breadth of the spaces (which might be either squares or parallelograms) contained between the bar and note lines, was again divided on the note lines into as many parts or spaces as the number of crotchets in a bar, and for notes of lesser value a less space was taken. While the paper was lying on a table, the notes in the tune proposed to be laid on the barrel were marked by a black ink dot on their respective lines, and in the same order as the bars of the music lay. After this was done, the paper was pasted on the barrel; the note lines now appeared like so many circles traced round the circumference of the barrel, while the bar lines lay longitudinally on the surface of it. By this means the black ink dots were transferred and marked on the barrel by a punch or finger drill. This mode might answer very well where large barrels were used, and only one tune laid on; but in smaller work, and where several tunes were to be put on the same barrel, it is neither sufficiently neat nor accurate.

We are not acquainted with the method adopted by those workmen in London who practise the pricking of music on clock barrels; but having had occasion to construct some musical clocks above thirty years ago, and having no opportunity of getting the music pricked on the barrels by any professional person, it became necessary to contrive some method for this purpose. One way consisted in applying the barrel concentric with the arbor of a wheel cutting engine, whose dividing part consisted of an endless screw and wheel; and having fixed other apparatus on the engine for this purpose, different numbers of turns of the endless screw were taken for the longer or shorter notes, and the tunes were as accurately put on the barrel as could be wished. Another way consisted in placing the barrel and its train of wheel work and regulating fly in the frame. A force was applied to turn the barrel, wheel work, and fly round, in the order of lifting the music hammer tails, and an apparatus was used to mark the dots on the barrel. The fly made 360 revolutions for one turn of the barrel; or, should this be thought too quick a train, it might be made by altering the numbers of the wheel teeth to make 250 or 260 revolutions for one turn of the barrel; the train or revolutions of the fly being fixed, was made use of in the same way as the endless screw in the former way, by taking a greater or a smaller number of turns of the fly for the longer and the shorter notes. Knowing the number of bars in the tune, and the crotchets in a bar, by calculation, the number of turns of the fly was obtained (and parts of a turn, if necessary) that a crotchet required, so that the tune might go round the barrel, leaving a small space for locking and running; this was all that was required to be known: quavers and semiquavers came to have their proportion according to the value of the crotchet. Although the process of putting tunes on barrels answered very well by both these methods, yet it was rather tedious, and attended with some trouble and embarrassment in the operation; and a more simple and easier method of doing this was afterwards contrived and adopted, by which we could lay on a tune with the greatest accuracy and expedition in nearly ten minutes.

Although bell music is not of a favourite kind, yet, for the benefit of such clockmakers as may be disposed to construct music clocks, and have not the opportunity of getting the music pricked on the barrel by those whose profession it is to do this sort of work, we shall give a description of the tool and its apparatus, which will be found very well adapted for this purpose, and also of the manner of using it.

Having a good strong turn-bench, such as those used by clockmakers for their larger sort of work, to the standards or heads of it let there be attached supports on each side; to the supports on the side nearest the workman, let there be fixed a straight cylindrical rod AB, about ten or twelve inches long, and in diameter a quarter of an inch, or even three-tenths of an inch. A spring socket CD must be made for this rod to slide easily and steadily along it, somewhat like the socket which slides on the upright stalk or rod of a watchmaker's glass stand. In the thick and strong part of this socket E is fixed a steel arm EFG, bent into a curve, which lies over and above the music barrel when in the turn-bench, as shewn in Plate CCCVIII. Fig. 2. at EFG. The steel rod AB may at pleasure be placed at any distance from the barrel, about an inch or rather more, and should stand parallel to the barrel arbor MN, and nearly in the same plane with it, but rather a little above this than otherwise. On the outer end of the curved arm is fixed a flat piece of steel G, a little more than half an inch long, in breadth not quite so much, and about one-tenth of an inch thick. The lower and front edges of this flat piece of steel should be neatly and smoothly rounded off, so as to allow it to come easily and freely into the notches *a*, *b*, *c*, &c. which are on the edge of a thin brass scale, whose use will come afterwards to be explained. To the supports attached to the turn-bench heads, and on the opposite side to that where the round steel rod is placed, let there be fixed a slip of brass XY, about ten or twelve inches long, an inch and a half broad, and nearly a tenth of an inch thick, the inner edge of which must be made to stand parallel with the barrel, and the flat side to stand nearly in a plane between the upper surface of the barrel and its centre, the edge being placed so as to stand clear of the tops of the teeth of a high numbered wheel WW screwed on to the end of the barrel. Near the ends of this slip of brass slits are made, through which screws *s*, *s*, pass that screw it to the upper side of the supports; the slits serving to allow it to be moved a little occasionally lengthwise when required. On the upper side of the slip of brass is fixed another, but not quite so thick, the length being about that of the barrel, and breadth one inch and three quarters. On the inner edge of this are made as many notches *a*, *b*, *c*, &c. as there are hammers, bells, or notes, to be used in the tune or tunes to be marked on the barrel. These notches are equidistant, and the middle of them should correspond to the middle or line of the hammer tails; their width being such as to admit the flat steel piece G on the end of the curved arm EFG; the depth of them cut on the edge of the brass should be about one quarter of an inch. The edge of this piece of brass, or music scale as it may be called, must also stand parallel with the barrel, and at a little distance from it, not nearer than three-tenths of an inch, so that the flat steel piece on the end of the curved arm may have room to get in a little way, and to pass through at the same time to a cetain degree of depth. On the upper side of this brass slip the letters of the scale of music or gamut are marked to those notches which correspond with the hammer tails, and hammers intended to strike on the bells the notes so marked, but in an inverted order to the usual way in which they are marked in the scales of music, the lower notes being on the right hand side, and as they rise going to the left. This is done to suit the way in which the bells are commonly, though not necessarily, placed in music clocks (See Plate CCCVIII. Fig. 3); for a clockmaker of any ingenuity might contrive the barrel to turn any way he thought proper, and place the bells to stand in the order of the music scale, if there was any advantage to be derived from it. In the curved arm EFG, Fig. 2. is fixed a punch *f*, having a very fine and sharp conical point, at the distance of four inches or so from the centre of the sliding socket, and not quite an inch from the outer end of the flat steel piece; the punch when applied to the barrel should stand upright, and directly over the centre of it. This apparatus being all adjusted as we have directed, it is evident that, when the curved arm is raised up a little way, the socket can then be made to slide easily along the steel rod, and by this means bring the outer end of the flat steel piece very readily into any notch required, and the point of the punch is brought at the same time with the greatest precision to the place of the note on the barrel, leaving the flat steel piece for the time in the notch: The point of the punch touching or resting on the barrel, a stroke from a very small hammer on the top of it will cause the point to make a pretty deep mark or conical hole on the surface of the barrel.

It now remains to be shewn how the time or the lengths of the different notes are determined. Long or slow, short or quick notes, such as the minim and demi-semiquaver, are not well suited to bell-music, and, of course, are seldom introduced into tunes chosen for it; the crotchet, quaver, and semiquaver, forming the greatest part of the composition: the minim and demi-semiquaver may, however, be brought in at some parts. It may be unnecessary to state, what is pretty generally known, the proportional value of the notes to one another; suffice it to say, that a minim is equal to two crotchets, a crotchet to two quavers, a quaver to two semiquavers, and a semiquaver to two demi-semiquavers. The time in which the barrel turns, after striking or lifting a hammer-tail, to strike any note on a bell, must be in the same proportion with the notes, according to their respective character. Let a wheel of 250 teeth, for example, be fixed on the end of the barrel, and let both be placed in the turn-bench, with the apparatus which has been described: To the turn-bench is now attached a steel or brass spring, having a knee or bending at one end, so that it may fall into the spaces of the wheel-teeth. The tune of the Jolly Young Waterman (See Plate CCCVIII. Fig. 5.) being proposed to be laid on the barrel, will, by inspection, be seen to contain 20 bars of three crotchets each, being 60 crotchets: if 250 the number of the wheel is divided by 60, the number of the crotchets, we shall have four for the quotient, and ten for the remainder; shewing that we may take four teeth or spaces for every crotchet, ten, the remaining part of it, serving as a run for locking, and the other part for a run at unlocking, for a tune to be played. Now as a crotchet is equal to four spaces, a quaver must be equal to two, and a semiquaver equal to one. In the tune proposed, the first note is F ♮; the curved arm is brought to the left hand, and the flat steel piece put into that notch; the punch is then made to mark the barrel; and this being a semiquaver, or the fourth part of a crotchet, the spring index is shifted into the next space of the wheel teeth, and the curved arm moved to the next note, which is G, on the left hand, and the flat steel piece being put into the notch corresponding to G, the punch is made to mark it on the barrel. This being a semiquaver also, the spring is shifted into the next space, and the curved arm moved to note A on the left; the steel piece is put into the corresponding notch, and the punch marks this on the barrel. A is here equal to a quaver and a half; therefore the spring index must be moved over three, or into the third space, and the curved arm moved to the next note, being B, on the left hand; the steel piece being put into this notch, the note is marked on the barrel; and as it is a semiquaver, one space is taken for it, and the arm moved to G. This being marked, and as it is a quaver, two spaces are taken, and so on. When crotchets are marked, four spaces are taken after marking them. In the tune which we have used, nine bells or notes are all that is required; and three more, or a dozen, would give such a compass as to take in almost any tune that might be required. In place of the spring index, it would be better to have a single threaded endless screw to work into the wheel teeth, one turn of which would be equal to a tooth or space. The arbor of the screw being squared on one end, and a small handle for turning it being put on, there would be less danger of making mistakes with the screw than with the index. On the arbor of the screw there might also be put a hand or index, to point to a circular space or dial of eight or ten divisions. This would give room to make parts of a turn, where great nicety is required. After one tune is laid on the barrel, either it or the music scale must be shifted a short space when the next one is to be put on. To shift the music scale is perhaps the preferable way of the two; and the spaces for shifting should be marked on the top of one of the supports, and close by one end of the long slip of brass; or they might be marked on a short line drawn longitudinally on the surface of the barrel, at or towards one of the ends of it; or by taking both methods, the one would serve as a check on the other. The length of shifting depends on the distance between the hammer tails and the number of tunes to be put upon the barrel. For example, if the distance between the hammer tails is four-tenths of an inch, and it is proposed to put eight tunes on the barrel, then, if we divide four-tenths by eight, we shall have half a tenth for the length or space to shift for each tune; and this is taking advantage of the whole space between the hammer tails, a circumstance which is frequently overlooked; for where the shifts have been confined to a less space for shifting than might have been got, so much room is lost. The distance between the hammer tails depends on their number, and on the length of the barrel. We have made the distance a quarter of an inch, where the number of hammers were eleven, and the length of barrel about three inches and a quarter, the number of tunes put on the barrel seven, the spaces for shifting were three hundred parts of an inch, or thereabouts, and where the clock of itself shifted the tune. When the hammer tails are thin, a number of tunes could be made to have their shifts in a very short distance between the tails; the diameter of the lifting pins must also be taken into account, being of some consideration where the spaces for shifting are extremely limited. Although we have taken the number of the wheel teeth for dividing the notes at 250, yet either a greater or less number may be assumed; all that is required is to proportion the number of turns of the endless screw, and parts of a turn, to the number of bars in the tune, and to the notes in each bar, and to have the tunes to go nearly round the barrel, so that a small part of a revolution of it, after the tune is played over, may be left for what is called locking and running. If the dividing wheel was taken at 128 teeth, and the tune being supposed to have 20 bars, each bar having three crotchets, as in the former example, 128 teeth divided by 60, the number of crotchets, the quotient would be two, and the remainder would be eight; so that each crotchet would require two teeth or turns of the endless screw, a quaver one turn, and a semiquaver half a turn, and the remaining eight teeth would serve for locking and running. When the tunes are all marked on the barrel, each mark must be drilled to obtain holes for the lifting pins to be driven into them. Great care should be taken to have a stiff and excellent drill, so as to run no risk of breaking, which would occasion a great deal of trouble; and it should be of such a temper, and well and judiciously whetted up, so that it may drill all the holes without requiring to be once sharpened up: the object here is to have all the holes of the same width, so that the lifting pins may be all of the same diameter. The holes being drilled, and the barrel polished, a number of pins should be prepared into lengths of half an inch or so each, and a very little tapered at one end. The stronger and harder the brass wire for the pins is, so much the better; some of the best kind of pins used in the female dress are very fit for this purpose. In placing the pins in the holes, if they should be found too long for knocking in by the hammer, they should be shortened by the cutting plyers before the hammer is applied, which will prevent bending, and allow the pins to have a more secure hold of the barrel rim. After all the pins are put in, they must now be shortened to an equal and proper length or height. For this purpose prepare a hard cylindrical steel collet, having a hole in its centre sufficiently wide to allow it to be put readily on the pins; the lower end of it hollowed, the upper end rounded, and the height of the collet about one-twentieth of an inch or a little more; the height depending on the size of the barrel and the diameter of the pins. The collet being placed on a pin, the cutting plyers are applied to cut the pin just over by the rounded end; a small touch of a file takes away the burr made by cutting, and as the hardness of the collet prevents the file from taking any more away from the height of one pin than from another, they must be all of an equal height. This operation being finished, the small burrs made on the top of the pins by the file must be taken off; this is done by a piece of steel wire, about six or seven inches long. The end where it is twirled about by the fore finger and thumb should, for the length of an inch or so, be made into an octangular form, for the more readily turning it round back and forward. On the face or point of the other end, two notches are made across each other, which may be either angular or round at bottom; the latter may be the better of the two, if rightly executed, and should be made with the round edge of a flat file, whose thickness should not be more than the diameter of the pins. The point where the notches are cut should be hardened, and the inside and bottom of the notches polished, so that a sharpness may be given to take away the burrs easily from the top of the pins.

The shape of the hammer tail is such as is represented at Plate CCCVIII. Fig. 3, a form which makes the hammer easy enough to be drawn, and the tail takes little or no room when falling; and should two pins or notes succeed each other rather rapidly, the nib or point of the hammer tail will not be interrupted by the succeeding pin. In the first musical clocks, and even in those made long afterwards, the bells were all placed on one strong iron bell stud, the opposite end of which was supported by what may be called an auxiliary stud, which occasioned a crampness that prevented the bells, when they were struck by the hammers, from vibrating, or giving out that full tone which they might have otherwise been made to produce; and the improvement made on this, as well as on the quarter bell studs afterwards, was effected by placing each bell separately on its own bell stud, which was made of well hammered brass, having some degree of elasticity. The sweetness given to the tone of the bells by this method was truly surprising. The bells in this kind of music may be sounding at the time that a succeeding note is struck out and sounding too, which may not be so pleasant to a very nice ear. This can be prevented by having a double set of hammers, and having every tune pinned twice over on the barrel, one set of the hammers having the heads of buff leather, or having a brass head with a piece of cloth sewed over it. These, when they strike the bell, will damp the sound of the note which is last struck. The buff hammer should fall on the bell to be damped, at the same instant that the brass hammer strikes the succeeding note on its bell. This improvement, however, must greatly increase the expence on such a clock; but the effect of buff or cloth hammers is so striking, that the additional price ought not to be grudged.

In Plate CCCVIII. Fig. 3, AA is a circle representing an end view of a clock music barrel, and a few of the lifting pins. The dart shows the direction in which it turns. The letters *a*, *a*, *a*, *a*, *a*, represent a section or end view of a brass piece thus shaped. The length depends on that of the barrel, and the number of hammers to be let into this brass piece, which is called the hammer frame, the length of it being sometimes three or four inches, sometimes ten or twelve. The flat part of the hammer tails fills up the thick part of the hammer frame, into which slits are made to receive the hammers. Near to the outer and lower angular part at *a* of the frame, a hole *h* is made through the whole length of it, not drilled, but ploughed, as the workmen call it, and this is done before any slits are made in it for the hammers. A wire is put through this hole, and through corresponding holes in the flat part of the hammer tails. This wire is their centre of motion, and the holes in them are made so as to have freedom on it, and the flat part of the hammer tails are also made to have freedom in the slits made to receive them. On the under side of the hammer frame at *b*, the hammer springs *c*, *c* are screwed, one for each hammer, acting on that part of the hammer tail just where it comes out of the thick part of the hammer frame. When the pins in the barrel raise up any hammer by the nib, and carrying it away from the bell, at the instant the pin quits the nib, the spring *c*, *c*, by its returning force, makes the hammer head give a blow on the bell, to elicit the sound. To prevent any jarring in the bell by the hammer head resting or touching it after having given the blow, each hammer has a counter-spring, acting near the lower end of the shank, and inside of it. All the counter-springs are made to project from one slip of well hammered brass, and screwed on the top of three kneed brass cocks, fixed to the upper side of the brass frame. *d d* is a view of the side of one of the cocks; and *e e* an edge view of one of the counter-springs. *f f* is a side view of one of the bell studs, which are also screwed on the upper side of the hammer frame: an edge view is seen at *f f*, Fig. 4. *g*, *g*, *g*, *g* are edge views of the bells. *g*, *g*, Fig. 4. is a side view of one of them as fixed to its stud. In some musical clocks, in place of the barrel being made to shift for change of tune, the hammer frame is made to shift, carrying with it all the hammers and bells. The change, or shifts of the barrel, is either done by hand or by the clock itself. The mechanism for this commonly consists of a wheel fixed on a steel arbor, on the square of which a hand is put, which points to the name or number of the tune marked on a small dial, at which the barrel for the moment stands. The diameter of this wheel is about one inch and a half, and sometimes more or less. The rim is a strong and thick hoop or contrate form, having as many steps on it as there are tunes set on the barrel, the height of the steps being equal to the space from one tune to another. On these steps rest the kneed end of a double lever about four inches long, whose centre of motion is in the middle, and is either upon strong pivots run into a kind of frame, or upon a stout pin, which goes through the lever and the brass stud in which the lever moves. The other end of the lever bears on the end of one of the pivots of the music barrel, which is pressed against it by means of a pretty smart steel spring, acting against the end of the opposite pivot. Concentric with the hoop wheel, and fixed on the same arbor, is a star wheel of a number according with the steps on the hoop wheel, a jumper with a pretty strong spring works into the star wheel, by which means the barrel is kept always to its place, by the lever bearing at one place on every step. Although the Figures which have been given to represent the hammer frame, hammers, springs, and counter-springs, bell studs, and bells of music striking, are not exactly like those which are commonly made to strike quarters in clocks, yet they are equally well calculated for the purpose; only the nibs of the hammer tails need not be so far from their centre of motion, being less confined by the pins in the quarter barrel, which are fewer in number than those on a music barrel. A quarter barrel need not be much in diameter, if five quarters are only to be put on it. If ten is intended to be put on, then the diameter should be double that of the other.

After having described the method of laying down the tunes on a music clock barrel, it may be thought unnecessary to explain the method of putting on the quarters of a clock quarter or chime barrel. But, simple as it is, we conceive it will be both interesting to the general reader, and acceptable to workmen who may not be in the habit of contriving for themselves, or who may not have had an opportunity of seeing it executed by others.

Quarters are commonly struck on a set of eight bells, from G to G in octave, or they may be numbered 1, 2, 3, &c. on to 8. The quarter barrel may have eight circles faintly turned on it, so as to correspond to the quarter hammer tails. Five, and sometimes ten, quarters are put on the barrel; we shall, however, in this instance only lay five on the barrel. Take a wheel cut into 50 teeth not rounded off, and screwed temporarily on the end of the barrel; provide an index, and a piece of brass bent so as to apply to the barrel when in the turn bench, in the manner of a straight edge, and the index spring tight in the teeth; take a point, and make a slight trace across the circle, which corresponds to high G or No. 1, then move the index a tooth, in the direction the quarter barrel turns when moved by the wheel work; make a trace across the circle intended for the second hammer, and so on. When the eighth circle has been marked, move the index two teeth for the first hammer of the succeeding quarter, and so on till the whole is completed; the barrel may then be drilled and pinned accordingly. Should the intervals between the quarters be thought too little for locking, the wheel, in place of 50, may be cut 55, and this will allow three teeth in place of two for the intervals. G, A, B, C, D, E, F G, may also be represented by the figures 1, 2, 3. 4, 5, 6, 7, and 8. No. 1. being the high G, and 8 the low G The changes given in the following set of chimes or quarters, will exhibit how to proceed in putting them on the barrel, after what has been already said.

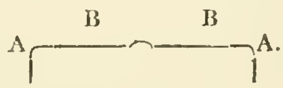
*A set of Chimes for Clock Quarters; the barrel making two revolutions in the hour.*

With the number of 8 bells and hammers for the quarters of a chime or quarter clock, a great variety may be produced; and where it may be preferred to have the chime or quarter barrel to make one revolution for the ten quarters which are given in the course of every hour, we shall give a specimen of a set of chimes which may be put on such a barrel.

*A set of Chimes for Clock Quarter Barrels, which make one revolution in an hour.*

*On Bells.*

It is still a point undetermined, whether the common shape of the bell, or that which is called the dish-form, and used chiefly in house clocks, is the best. The great expence which attends experiments on bell founding will probably keep this point long undecided. Being in possession of a manuscript, containing some of Professor Ludlam's remarks on the subject of bell founding,* which we conceive to be very valuable, we shall lay them before our readers. "I saw a great deal of the art of bell founding," says Mr Ludlam, "in the time of the late Mr Thomas Eayre of Kettering, a man who had a true taste for it, and spared no expence to make improvements. Much of tone depends on minute circumstances in the shape; and Mr Eayre had crooks or forms cut on thin boards, carefully taken from the inside and outside of all the good bells he could find. This county (Cambridge) and Northampton abounds with the best bells I ever heard, cast by Hugh Watts of Leicester, between 1630 and 1640. Ringers in general, who are commonly constituted the judges of bells, (and as such are feed by the bell founder,) regard neither tune nor tone. The hanging of the bell is all they regard, that they may show their dexterity in change-ringing. That shape of a bell that is best for tone, (a short one,) is not the best for hanging, so tone is utterly disregarded; to please the ringers, and to get money, is all. In my opinion, the thinner the bell and deeper the tone the better, provided it is not shelly, that is, like a thin shell, with such a tone as the fragments of a broken Florence-flask will give. A deep tone always suggests the idea of a great bell, is more grave, and better suited to the slow strokes of a church clock, and is heard farther. The clock in St Clement Dane's church in the Strand, London, strikes the hour twice—once on the great bell in peal, and again on its octave or 12th, I know not which; listen to them, and you will perceive which is most agreeable and best heard. The son of Mr Thomas Eayre, who was a good bell founder, cast a dish-bell of five or six hundred weight, for the church clock at Boston, in Lincolnshire, the tone of which was very deep and wild. Mr Thomas Eayre, very early in life, made a curious chime for Sir T. Wentworth, afterwards Lord Malton, and father of the Marquis of Rockingham, which had thirteen dish-bells, the biggest about two hundred weight. This is at Harrowden, near Kettering. Thomas Eayre, his son, and his brother Joseph, being all dead, to their bell-founding business one Arnold succeeded, who had worked with Joseph Eayre, and is now at St Neot's, Huntingdonshire. Arnold I believe to be a much better bell founder than the White Chapel bell founders, though by no means equal to old Thomas Eayre. Romilly always would confound Thomas Eayre with Joseph Eayre, and so imputed the faults of the one to the other. Romilly was so conceited when at Leicester, where there is undoubtedly the best peal of bells in the kingdom, (partly old Watt's and partly Thomas Eayre's,) that he would not so much as deign to hear them. I cannot help thinking that a bell of five or six hundred weight, of the dish form, might be cast far fitter for your purpose, than one of the church form. But who will do it? Who has had any experience of bells of this form? It must also be observed, that small differences, in the form, in the shape or thickness of the sound-bole of a church bell, will make great differences in the tone. All I can say is, it is not the weight of metal, but something resulting from the shape of the bell, that gives both freedom and depth of tone, as I can prove by many instances. What that shape is that makes a bell so willing to speak, is a question which a good bell founder ought to be able to answer. It is a known and undoubted fact, that a bell speaks much better, when both the clapper and the bell is hammer hardened, and when they are worked in to touch each other in many points. I now recollect, that above 40 years ago, Thomas Eayre made a large turret clock, with quarters, for Lady E. Germain, (now Lord G. Germain's,) at Drayton, near Thrapton, Northamptonshire, all the bells of which are *Dish-Bells* of a large size. I know not their weight exactly, but suppose the biggest four hundred weight—they are heard a great way."—"There is an instrument brought from China, called a gon or gong, made of hammered brass, or of some sort of a metallic composition, about 16 inches over. The drawing is a section of it.



What I call the sides AA are about four inches deep, and seem to supply the office of the sides of a drum, while the flat part BB answers to the stretched parchment; only there is a round part in the middle to stiffen it. On this raised part you beat with a ball of packthread of four or five inches diameter, fastened to the end of a stick. The metal, at a mean, is about one-eighth of an inch thick, but unequal, the whole form being manifestly raised out of a flat plate by the hammer. The tone is amazingly deep, clear, and sonorous. The note of that I saw, and had some time in my possession, was F, an octave below the F faut cliff in the bass." See our article GONG.

That music which is produced by clocks with organ barrels must be greatly preferable to that of bells, and the apparatus for marking the tunes on clock barrels is equally suited to do the same on barrels intended by machinery to work or to sound the pipes of an organ; the

* These remarks are contained in a series of unpublished letters written by that eminent Professor, and copies of which are in the possession of the writer of this article. See p. 480, col. 2. of this article.

difference consisting in marking off on the barrel the spaces of the longer and shorter notes, as in place of pins they have staples or bridges of various lengths, according to the length of the note, or the time which the pipe should be allowed to sound it: The very short notes are by pins of different thicknesses. When an organ part is put to a clock, considerable power or force of weight or spring is required; small as the organ may be, or its wind chest, some force is required to work the bellows, so as to keep the wind-chest full, and no more. To work the bellows, that is, to move the lower board of them up and down, on the inside of which is an air valve that opens on the board being moved downwards, and on the motion upwards it shuts, and the air being then compressed, it is forced into the wind-chest by a communication between them for that purpose, and is ready to give sound to any of the organ pipes the moment when any of their valves should open. This operation with the bellows, though of a different shape, is just the same as with the common bellows when blowing up a fire. The bellows is worked by means of a short crank fixed on one end of the arbor of an endless screw, which works into a trundle of a high numbered pinion, which is on the end of the organ barrel, and nearly of the same diameter with it. On the other end of the endless screw arbor is fixed a small jagged pulley, over which is put an endless silken cord, which being continued, goes round another jagged pulley on the end of a pinion arbor of one of the quick running or fly wheels in the organ train. These wheels are regulated by a fly, by which the velocity of the organ barrel in turning is brought to keep the time required for the music. The wheels, on being impelled by the moving power, which is considerable, (being greater than that used in bell music,) communicates their motion by means of the endless cord, and turns the organ barrel. The pins, bridges, or staples, on the barrel turning, act on the tails of levers nearly similar in form to the hammer tails of the bell musical clock, only they are a little longer, and equally moveable on a centre or wire. The other arms of these levers are in an opposite direction, and are about the same length as those which are lifted by the staples on the barrel when turning, and are a little broad and flattish towards the end, where the under side (on the opposite ends rising) press down on the upper ends of the slender rods, whose lower ends then by this means open the valves of the organ pipes, and the sound is prolonged according as the lift is pins or bridges. What has been described constitutes the chief machinery in an organ clock. Many ways may be contrived to set the organ barrel in motion, and at the same time while playing, and at the end of a tune, to make the clock of itself shift the barrel from one tune to another.

Within these two or three years, a new species of music by steel springs has been invented at Geneva. From the smallness of the machinery which plays the music, it is very surprising and curious, as it has been put into rings, seals, watches, and snuff boxes. Two ways are used to lift the ends of the springs which give the different notes; one is by a very small barrel, the other by a plate wheel. The last, being more adapted to take up little room, is chiefly used in watches. The space for the springs falling, after being bent up, is short. A double set of springs for giving the same notes is made, without which the beauty of the music could not be produced. The number of springs varies, for the most part, from sixteen to twenty-four, or upwards. Those springs which are lifted by the barrel pins are straight, while those which are lifted by the pins in the plate wheel have a sort of part projecting from the end at one side; and this side edge of the spring lying over the top of the pins is taken away, so as to clear them. The projecting part at the end of each spring corresponds with its own lifting pin. As the pins are on both sides of the plate-wheel, this allows a greater variety of notes than the barrel can perhaps admit. The springs on the upper and under sides of the plate-wheel are sometimes sixteen or seventeen on each side. On the plate-wheel are traced 16 or 17 concentric circles, for the pins to meet their corresponding notes in the springs, whose ends come each to their corresponding circle both above and under the plate-wheel. An apparatus on a small scale being made like that which has been described, will serve to put or mark the places for the notes both on the barrel and the plate-wheel; the only difference is, that the barrel will require to be marked by a curved arm sliding on a steel rod. The concentric circles on the plate wheel must have short and faint traces across them: This is regulated by a thin straight edge, laid in an oblique direction across the circles, and the intersections are afterwards marked by a point. The springs may be easily tuned to their respective notes, as the least thinning or shortening them will make a very sensible alteration on the tone. The tongue of a steel trump, or Jew's harp, shews, in some degree, what may be done in this way by steel springs. The train which regulates this very minute musical machinery, as may very easily be conceived, must be composed of a few very small wheels, the motive force being proportionably small. It must be a great effort of patience and ingenuity to make them play two or more tunes. However beautiful and ingenious the machinery of these small contrivances is, they can only be considered as toys for amusing children.

HORSEMANSHIP. See Manege.

HORSLEY, Samuel, one of the most eminent theologians in modern times, was born in October 1732, and was the eldest son of the Rev. Mr Horsley, minister of St Martins in the Fields. He received the classical part of his education at Westminster School, from which he was removed to the University of Cambridge, where he applied himself principally to mathematical studies. After having taken his degree as master of arts, he went to Oxford, in the capacity of private tutor to the Earl of Aylesford, where he received the degree of doctor of laws. On leaving this university, he came to London, where he was elected a fellow of the Royal Society, of which he was chosen secretary in 1773. He published several valuable papers in the Transactions of that learned body, and continued to discharge the duties of his office in a very distinguished manner, till the resignation of the president Sir John Pringle in 1778. Soon after his having settled in London, he accepted the office of chaplain to Bishop Lowth, one of his greatest patrons, who presented him to the rectories of St Mary Newington and Albury in the county of Surrey; appointed him Archdeacon of St Albans in 1778; and, in 1782, conferred upon him the valuable living of South Weald in Essex. In 1788, he was raised to the bishopric of St David's by the interest of Lord Thurlow; and, in 1794, was translated to the see of Rochester, holding at the same time the deanery of Westminster. In 1802, he was promoted to the see of St Asaph; and is generally understood to have had his Majesty's promise of the Archbishopric of York. He died at Brighton on the 4th of October 1806.

These numerous promotions, and high prospects as a dignitary in the English Church, were fairly earned by the eminent services which he rendered to the cause of sound principles and sacred literature. In 1769, while residing at Oxford, he published a valuable edition of Apollonius, and discovered his thorough qualifications for illustrating the works of the ancient geometers. In 1799, he produced an edition of Newton's Works, in five volumes 4to, with commentaries and separate dissertations; an undertaking, in which he is generally allowed to have done more than could reasonably have been expected from one, whose acquirements on other subjects were so diversified and distinguished; but, at the same time, to have failed in that full illustration of his author, which the improved methods of calculation and analysis might have accomplished. In 1778, he published a sermon on the consistency of the doctrine of Divine Providence with the free agency of man, in which he combats the necessitarian tenets with great ability. In 1789, he collected and printed in one volume the tracts which he had written during the preceding six years, in his celebrated controversy with Dr Priestley on the Unitarian system; a discussion in which he is now generally acknowledged to have had a decided superiority, both in learning and argument, and in which his productions must always be read as standard works, and admired as models of clear and powerful reasoning. In 1790, he published a pamphlet without his name, entitled "A Review of the Case of the Protestant Dissenters," in which he vindicates in a highly nervous style the high church principles on the subject of the test laws. In 1796, appeared from his pen a very learned dissertation on the Latin and Greek Prosodies; in 1800, a critical disqusition on the 18th chapter of Isaiah, in a letter to Lord King; in 1802, a new Translation of the Prophet Hosea, with critical and explanatory notes. Besides many smaller pieces, he was the author of an Elementary Treatise on the fundamental principles of Practical Mathematics, which appeared in three volumes in 1801 and 1803, and of a Critical Essay on Virgil's Two Seasons of Honey, and his Season of Sowing Wheat, with a new and compendious method of investigating the Rising and Setting of the fixed Stars. There have been published, since his death, three volumes of his Sermons, a volume of his Charges, a volume of his Speeches in Parliament, and a Translation of the Book of Psalms with notes. He has also left in manuscript, a Treatise on the Pentateuch, and on the Historical Books of the Old Testament; and a Treatise on the Prophets, containing Notes on Isaiah, Jeremiah, Ezekiel, Joel, Amos, and Obadiah; which are announced to be in a state ready for the press, and which, it is to be hoped, will not be suffered to be lost to the Christian world by any want of encouragement on the part of the public. His son, the Rev. Heneage Horsley, proposes to publish an uniform edition of all his father's works, with a biographical account of the author.

The name of Bishop Horsley stands unquestionably in the first rank of the scholars and divines of the present age. His intellectual powers were of the highest order, and of so versatile a nature, that wherever he applied his attention, he was generally sure to take precedence. He possessed an almost inexhaustible activity of mind united with an ardent spirit of research, and a capability of constant exertion, which, had his pursuits been less various, might have raised him to a still higher point of eminence. In the mathematical and physical sciences, he held a respectable station. In metaphysical acuteness and research, he had few superiors. In classical attainments, and particularly in a critical knowledge of the sacred languages, he occupied the very foremost rank of excellence. In the most recondite theological erudition, he was not surpassed by any of his contemporaries. And, in the church of which he was so distinguished an ornament and support, he was pre-eminent for his consistency and decision, as the champion of a sound and scriptural creed. In public speaking, his voice was sonorous and commanding, and his whole elocution distinct and impressive. In the duties of his Episcopal office, he was eminently exemplary; and, in the see of St David's particularly, he strenuously exerted himself to accomplish a regular system of improvement in the qualifications and condition of its clergy. He examined in person the candidates for holy orders, and inspected carefully the titles which they produced. He treated them, at the same time, with paternal kindness, encouraging them to visit him, assisting them with his advice, and ministering, with a bountiful hand, to their temporal necessities. In his progress through his diocese, he preached frequently in the parish churches, and bestowed liberal donations on the poor. In the House of Peers, he supported the character of an enlightened and eloquent senator; and took a part in most of the important discussions of his time. In his political and ecclesiastical sentiments, he must be classed, and readily classed himself, among high churchmen (a term, which we profess to use not as vituperative, but merely as descriptive;) but it has never been doubted, that his zeal was conscientiously sincere; and it is certain, that, on many occasions, he discovered a greater degree of genuine liberality and practical toleration, than many who were louder in their pretensions. He was a systematic opponent of the slave trade; and is understood, on good authority, to have been anxious to enter into a parliamentary enquiry into the claims of the Irish Catholics, with a view to grant them whatever privileges might have appeared compatible with the security of the Protestant succession and the Protestant establishment. He was an earnest advocate for mutual forbearance between the two most respectable parties in the Church of England; and the decision of his comprehensive mind on the points in dispute deserves to be emblazoned in every vestry of the English and Irish establishments. "The Calvinists contradict not the avowed dogmata of the church; nor has the church in her dogmata explicitly condemned or contradicted them." He has been charged with harshness and dogmatism in his character and manner, especially as a controversialist, and it would not be easy to exculpate him wholly; but much of this intolerance, often more apparent than real, evidently arose from his zeal for the truth which he defended, and his high sense of its importance. His language, at the same time, however strong, was always dignified; and his works in general rather display an undisturbed liberality of judgment and expression towards the advocates of conflicting opinions. Even his sternest polemical tracts contain many expressions of the most magnanimous candour, of which the following conclusion of one of his letters to Priestley may be given as a striking specimen. "The probability, however, seems to be, that, ere those times arrive, (if they arrive at all, which we trust they will not) my antagonist and I shall both be gone to those unseen abodes, where the din of controversy and the din of war are equally unheard. There we shall rest together, till the last trumpet summon us to stand before our God and King. That whatever of intemperate wrath and carnal anger hath mixed itself, on either side, with the zeal with which we have pursued our fierce contention, may then be forgiven to us both, is a prayer which I breathe from the bottom of my soul, and to which my antagonist, if he hath any part in the spirit of a Christian, upon his bended knees, will say, Amen." # HORTICULTURE.

1. By the term Horticulture, is to be understood the whole management of a garden, whether intended for the production of fruit, of culinary vegetables, or of flowers. The formation of a garden may be included also, to a certain extent, under this subject: draining, inclosing, and the forming of screen plantations and hedges, may be considered as parts of horticulture; while the general situation of the fruit and the flower gardens, in regard to the mansion-house, and the position of some of their principal component parts, as shrubberies, hot-houses, parterres, and walks, belong more properly to Landscape-*Gardening*; which see.

It is evident, that the horticulture of every country must vary in its nature and objects, according to the climate. The great end of this article will be, to exhibit as correctly as possible the present state of gardening in Britain, noticing particularly the improvements which have recently been introduced, especially since the close of the 18th century. After a general prefatory account of the rise and progress of horticulture in this country, we purpose to give a short view of the different kinds of gardens now existing; and then to treat of some general matters, such as situation, soil, manures, enclosure-walls, &c. After this, the fruit garden will be particularly attended to; the various kinds of fruit-bearing plants will be mentioned, and the most esteemed varieties of each; and here the different kinds of forcing-houses will claim attention. The kitchen garden will fall next to be discussed, in the same minute way. After which, the flower garden will be considered; but here abridgment must be studied; for to speak of *all* the ornamental plants cultivated would be an endless task: the delicacies of Flora will not, however, be neglected, and the sorts called "florists' flowers" will be enlarged upon. A few remarks on the diseases of plants, and on their prevention or cure, will conclude the whole.

Without detaining the reader with trite remarks on the antiquity of gardening, or discussions concerning the celebrated groves of the Hesperides, the hanging terraces of Babylon, or other gardens of remote ages, we shall at once proceed to give some short account of the rise and progress of modern horticulture. In doing this, it will be necessary to confine our attention almost exclusively to our own country. To discourse of the progress of the art in other countries would not only swell this part of the article to an improper size, but would be an unprofitable undertaking. Nothing can be more evident than the fact already hinted at,—that the practice of gardening in one country cannot be applied to any other, unless that other greatly resemble the former in climate. Useful hints may no doubt be occasionally drawn, from observing the modes in other countries. But it is scarcely necessary to remark, that in warm climates the practice must differ very widely from that which obtains in the temperate or the cold. In the former, the plants, which require to be fostered in our stoves, either grow spontaneously, or are cultivated in the open fields; while the greater part of our common pot-herbs* refuse to flourish in sultry regions. Again, the far northern countries of Europe, Sweden, Norway, and Russia, possess peculiarities of climate: snow covers the soil throughout the winter, and the summers are uninterruptedly bright and warm. Even in Britain, such is the difference of climate between the favoured counties of the south-west of England, and that part of the island which lies to the north of the Cheviot Hills, that the same rules cannot be applied to both, without very considerable modification. The horticulture of the north of France, of Belgium, Holland, and Denmark, may in general be considered as approaching to that of South Britain; and these countries may frequently afford mutual lessons to each other, each availing itself of the other's discoveries, and adopting its improvements.

2. The origin of British horticulture is completely involved in obscurity. It may in general be asserted, that most of our best fruits, particularly apples and pears, were brought into the island by ecclesiastics, in the days of monastic splendour and luxury, during the 12th, 13th, 14th, and 15th centuries. Gardens and orchards ("orti et pomaria") are frequently mentioned in the earliest chartularies extant; and of the orchards many traces still remain, in different parts of the country, in the form, not only of enclosure-walls and prepared fruit-tree borders, but of venerable pear-trees, some of them still abundantly fruitful, and others in the last stage of decay. Of the state of horticulture previous to the beginning of the 16th century, however, no distinct record exists. Till then, it is generally said, that some of our most common potherbs, such as cabbages, were chiefly imported from the Netherlands, their culture not being properly understood in this country; but of this there is no distinct evidence, and the thing seems unlikely. From the "Itinerary" of Leland it appears, that even greenhouses were not then unknown in England.

3. During the reign of Henry VIII. rapid steps of improvement were made in horticulture. According to some authors, apricots and musk-melons were introduced by that monarch's gardener; and different kinds of salad herbs and esculent roots were, about the same time, first brought into the country from Flanders. Henry had a fine garden at his favourite palace of Nonsuch, in the parish of Cheam in Surrey. Here Kentish cherries were first cultivated in England. The garden wall was fourteen feet high; the wilderness occupied ten acres; "lelacke trees which beare no fruit, but only a plesaunte flowre," are mentioned among the rarities contained in it; as are also yew and lime trees. In the year 1534, Fitzherbert, the father of horticultural writers, published his "Booke of Husbandrye."

4. Queen Elizabeth was both a horticulturist and a florist, if we may believe a poet celebrating majesty:

*Cultor herbarum, memor atque florum.*†

During her reign, Dydimus Mountain published the "Gardener's Labyrinth;" Hyll, the "Profitable Arte of Gardening;" and Leonard Mascall, (the introducer of several good pippins,) the "Arte and Manner how to

* By the term *pot-herbs*, gardeners and green-grocers frequently understand only aromatic plants used for seasonings: we use it, correctly, to signify the *olera* in general.

† *Archæologia*, vol. vii.

plant and graffe all sorts of trees," &c.: While Barnabe Googe, Esq. translated the "Foure Bookes of Husbandrie of Conradus Heresbachius." All of these works are printed in black letter, and have become extremely rare. With the exception of the first mentioned, they are, generally speaking, little more than compilations from Varro, Columella, Palladius, Cornelius Agrippa, Cardanus, and some old French and Italian writers. In Elizabeth's days, carnations were, it is said, first cultivated by the Flemings at Norwich, and nearly at the same time tulip roots were brought from Vienna to England. Orange and lemon trees now became known. The "Herball, or Historie of Plants," by John Gerarde, first appeared in 1597; and a second edition, enlarged and improved by Johnston, came out about forty years afterwards. It may, in passing, be remarked as somewhat curious, that so distinguished a writer as Gerarde, and a piece so well known and frequently quoted as his "Herball," should not be mentioned by Professor Martyn, in his chronological list of authors and books on gardening. Towards the close of the 16th century, Sir Hugh Platt published "The Jewel-House of Arte and Nature," a little book not destitute of merit; and early in the following century appeared a posthumous work of his, called "The Garden of Eden."

5. A fine garden was formed at Theobald's, near Waltham Abbey, by James VI. (I. of England). In the year 1640, about thirty years after the formation of this garden, it was described by Mandelslo* as a large square, surrounded with fruit-tree walls, containing also espalier trees on some sort of trellises, and ornamental arches of trees; besides a parterre for flowers.

6. His son Charles I. seems to have patronized gardening. He appointed the celebrated Parkinson his herbarist. In 1629, appeared the first edition of this man's great work in folio, entitled "*Paradisi in sole Paradisus terrestris;* or a Garden of all sortes of pleasant Flowers, with a Kitchen Garden of all manner of Herbs and Roots, and an Orchard of all sort of Fruit-bearing Trees," &c. This may be considered as the first general book of English gardening possessing the character of originality. From his lists of flowers, shrubs, and fruits, the state of our gardens at that period may be pretty accurately guessed. The laurel or bay-cherry was then very rare, and considered as a tender plant, being defended "from the bitterness of the winter by casting a blanket over the top thereof;" and the larch tree was only nursed up as a curiosity. For the culture of melons, he recommends an open hot-bed on a sloping bank, covering the melons occasionally with straw,—the method practised in the north of France at this day. Cauliflowers, celery, and finochio, were then great rarities. Virginia potatoes (our common sort) were then rare; but Canada potatoes (our Jerusalem artichoke) were in common use. The variety of fruits described, or at least mentioned, appears very great. Of apples, there are 58 sorts; of pears, 64; plums, 61; peaches, 21; nectarines, 5; apricots, 6; cherries, no fewer than 36; grape vines, 23; figs, 3; with quinces, medlars, almonds, walnuts, filberds, and the common small fruits. The number of approved apples, pears, plums, and cherries, at the present day, is not nearly so large. Of florists' flowers, he mentions about 50 varieties of hyacinth; above 60 anemonies; but only 20 ranunculuses.

7. In the time of the Commonwealth, Walter Blith produced rather an ingenious work, with the quaint title of "English Improver improved, or the Survey of Husbandry surveyed;" and Ralph Austen published a "Treatise of Fruit Trees," also a book of merit.

8. After the Restoration, Charles II. brought over Le Nôtre, the favourite gardener of Louis XIV. and designer of the gardens of Versailles, to lay out and plant St James's and Greenwich Parks, which still remain very creditable monuments of his taste. Rose, who was gardener to Charles, had studied the art in France. It is remarked by the Honourable Daines Barrington, that at the installation dinner at Windsor, 23d April 1667, cherries, strawberries, and ice-creams, were produced, shewing that the king possessed both hot-houses and ice-houses, and that his gardener was an adept at forcing, for strawberries require considerable nicety of management.

9. From about the middle to the end of the 17th century, the well known John Evelyn, Esq. was the chief promoter of almost all horticultural improvements, forming an era in the history of British planting and gardening. Soon after returning from his travels on the continent, he translated "*Le Jardinier François*, instructing how to cultivate all sorts of fruit-trees and herbs for the garden." In 1664 appeared his celebrated "Sylva, or a Discourse of Forest Trees; with Pomona, an appendix concerning fruit-trees; Acetaria, a discussion of salads," &c. His "*Calendarium Hortense*, or Gardener's Almanack, directing what he is to do monthly throughout the year," was also at first added to the Sylva, but was soon afterwards published separately, and went through many editions. This useful manual laid the foundation of the successive *Gardener's Calendars* which have been published by Miller, Abercrombie, and Nicol. In 1693, his translation of Quintinye's "Complete Gardener" made its appearance, in folio; and, six years afterwards, he ushered into the world an octavo edition, "abridged and improved by George London and Henry Wise," two of the most distinguished gardeners and nurserymen of their day, and whose names have been consecrated by Addison, in his paper on gardening, in the "Spectator," (No. 477.) They had both been apprentices of old Rose, and succeeded him in the office of royal gardener. They converted an old gravel pit in Kensington Gardens into a picturesque hollow of foliage, producing an effect in gardening which the critic compares to the sublime in epic poetry, and exclaims, "Wise and London are our heroic poets!" It is curious, that while the labours of Evelyn justly placed him at the head of the improvers of his time, he should have missed an opportunity, fairly placed within his reach, of handing down his name as the greatest horticultural benefactor of Britain. In March 1662, it was proposed to the Royal Society to recommend the cultivating of potatoes, with the view of preventing the recurrence of famine; Evelyn was particularly consulted, and was requested to mention the proposal at the end of his Sylva, then announced for publication. He does not seem to have complied with this request, nor to have paid any attention to the culture of the plant: he merely mentions it in his Acetaria, and dismisses it with apparent indifference. This American plant, however, has proved a treasure to this country, "compared with which the mines of Potosi are worthless."

10. During the period of which we are speaking, several books on gardening came out, some of them countenanced by Evelyn, and others in which he took no share. One of the earliest of these was the translation of an essay on the management of fruit-trees, by the Sieur Le Gendre, curate of Henonviile, "wherein is treated of nurseries,

* Travels by John Albert de Mandelslo, near the end. In the English translation, the account of King James's garden, &c. is omitted, as uninteresting!

wall-fruits, hedges of fruit-trees, dwarf-trees, high standers," &c. He wrote from the experience of a long life, the leisure of which had been spent in the "ordering of fruit-trees." He was one of the first who attended to the proper training and pruning of wall trees; he boldly condemns the absurd taste, then prevalent, of cutting fruit-trees into the shape of lions or pyramids, but he was not able to divest himself of the doctrine of the moon's influence, and the necessity of planting and pruning only at certain periods of her waxing and waning. About the same time, Dr Robert Sherrock published "The History of the propagation and improvement of vegetables by the concurrence of art and nature;" a work containing a reasonable portion of information, disguised with a good deal of pedantry. Soon after, John Rea, gent. published his "Flora, or a complete Florilege," folio, in three parts: "1. Flora, treating of the choicest plants, flowers and fruits, that will endure our winters; 2. Ceres, containing such plants or flowers as are yearly, or every other year, raised from seeds; 3. Pomona, treating of the best garden fruits, of evergreens, and flowering shrubs." This was followed, first, by a "*Systema Agriculturæ*," and then by a "*Systema Horticulturæ*," by J. W. (John Worlidge) gent; and by the publication of the "English Gardener," by Leonard Meager, "above thirty years a practitioner in the art of gardening." This last contains a good deal of useful information: it is divided into three parts; 1. Of planting stocks, fruit-trees, and shrubs; 2. Kitchen garden; and, 3. Garden of pleasure.—The second volume of Sir William Temple's Miscellaneous Works, it may be mentioned, contains a curious account of the state of gardening in England in the close of the 17th century.

11. King William and Queen Mary appointed Dr Plukenet, a man distinguished for botanical knowledge, and author of a Phytographia and other works, to be their herbarist; and, under his directions, collectors were dispatched to the Indies in search of ornamental plants.

12. Early in the 18th century, Lawrence published "The Clergyman's Recreation, shewing the pleasure and profit of the art of gardening." But Richard Bradley, F. R. S. and Professor of Botany at Cambridge, soon eclipsed all other writers of this period, both for the number and the influence of his horticultural publications. They exceeded twenty in number, and were generally written in a popular style: several of them, as might be expected, are mere compilations, and others are avowed translations. The writings of Switzer, however, about the same time, also acquired a share of celebrity. They extend to six volumes in octavo, embracing, besides "*Ichnographia rustica*," a "Practical fruit gardener," and a "Practical kitchen gardener."

13. In 1724 appeared, in two octavo volumes, the first edition of the "Gardener's Dictionary," by Philip Miller, of the Botanic Garden at Chelsea. He professes to collect and digest the labours of his predecessors; but the book partakes largely of the character of an original work, and it soon attracted general notice. He asserts that gardening never arrived to any considerable pitch in England till within thirty years last past, *i. e.* from 1690 downwards. Seven years after the publication of the octavo edition, which is now very scarce, the first folio edition came out. In the preface he gives some account of ancient gardens, and also of English gardens, in the time of Charles the Second and William and Mary. The descriptions of numerous plants introduced into England, chiefly from America, during the first half of the 18th century, with details of horticultural improvements of different kinds, gradually swelled the work to two volumes in folio. In each successive edition (as observed by Dr Pulteney*) it received such improvements and augmentations, as have rendered it in the end the most complete body of gardening extant. In evidence of the estimation in which it is held on the Continent, it is enough to mention, that there are French, German, and Dutch translations of it, and that some of the continental writers bestow on the author the title of *hortulanorum princeps*. Till the seventh edition, the system of Tournefort was followed. In this the names and system of Linnæus were adopted. In the eighth edition, being the last published by Miller himself, he informs us, that the plants then cultivated in England (1768), were more than double the number known when the first folio edition appeared (1731.) In this edition the plants were first distinguished by the short *trivial* names, invented by Linnæus to supersede the tedious *specific* denominations previously in use. The Gardener's Dictionary, it may here be added, has since been enlarged and improved by the late Professor Martyn of Cambridge, and brought before the public in four volumes folio, forming, as he very modestly styles it, "a digest of what was known in gardening and botany at the end of the eighteenth century." This great undertaking occupied the learned and laborious professor for nearly twenty years; but it is a work which will long maintain the horticultural reign of the name of Miller, and which is calculated at the same time to establish his own fame.

14. In the early part of Miller's time, Batty, Langley, and Ellis, published various horticultural works of some merit. In 1755 Thomas Hitt produced his "Treatise on Fruit-Trees;" and in it he proposed an improved mode of training wall-trees, by regular horizontal branches, with upright bearers. This is a work well deserving of attention; and the author has not, it is believed, received all the praise to which he is entitled. While practical works, such as those now mentioned, engaged the attention of horticulturists in general, some philosophical pieces also appeared, and justly acquired celebrity for their authors; particularly, "Vegetable Statics" by Hales, and the "Principles of Agriculture and Vegetation" by Dr Francis Home, father of the present distinguished professor of Materia Medica in the University of Edinburgh.

15. From the middle to the end of the 18th century, one of the most popular and useful writers on horticultural subjects was John Abercrombie, who, either from diffidence or some other motive, at first published his writings under the borrowed name of *Thomas Mawe*. It is said he was patronized and encouraged by the celebrated Dr Oliver Goldsmith. He was the son of a market-gardener near Edinburgh, and had gone into England when a young man, and after acting as a workman for some years at Kew Gardens, had been enabled to begin business as a nurseryman at Hackney. The work entitled "Every Man his own Gardener" has passed through at least twenty editions. This is formed on the plan of a calendar, containing practical instructions under detached monthly heads. Before his death, which happened in 1806, he had prepared another work, entitled "The Practical Gardener," in which the systematic method is adopted, of connecting under one article every thing relative to the culture of the same plant. This last has been published in the form of a thick duodecimo volume. He wrote also, "The British Fruit Gardener," "The complete Forcing Gardener," and "The Complete Kitchen Gardener, and Hot-bed Forcer," and still other books of similar import. It is

* Sketches of Botany in England, Vol. II.

perhaps to be regretted, that he was induced by booksellers to multiply his publications so much, this circumstance having tended to bring upon him the imputation of book-making, and to excite some degree of prejudice against him. In point of fact, however, he understood the business of gardening extremely well, and his writings altogether afford a very complete view of horticultural operations.

16. Another deservedly popular work on horticulture remains to be noticed. It is written by the Rev. Charles Marshall, a clergyman of the church of England, who is evidently a very zealous amateur gardener. The title is, "An Introduction to the Knowledge and Practice of Gardening." A great deal of correct information is here condensed into little space, and conveyed in perspicuous and unaffected language. There is subjoined to it a compendious *calendar*, better calculated, we think, to be useful as a remembrancer, than any one published since the time of Evelyn.

17. The "Dictionary of Gardening," bearing to be written by *Alexander Macdonald*, *gardener*, in two volumes 4to, is an expensive work, which has not acquired much reputation. It appears to be little more than a compilation, and is certainly not the work of a practical gardener; but it necessarily includes a great deal of useful information. Of late years, the culture of the vine and of the pine-apple has been very well treated by Speechly, in separate works. Forsyth's "Treatise on Fruit-trees and their diseases, with a particular method of cure," first appeared in 1791, in 4to. The royal patronage, kindly bestowed on an old and meritorious servant, secured to this work a considerable degree of attention, and even procured for the author the extraordinary distinction of a parliamentary reward. Many excellent remarks are to be found in the book. In 1802 it was republished, with improvements, in an octavo form.

18. Curtis's "Botanical Magazine" was begun in 1787; and it has been continued in monthly numbers, with little intermission, ever since; Dr Sims having edited the work since Mr Curtis's death. Important hints are frequently thrown out as to the habits, mode of cultivation, and uses, of the plants described and figured. Maddock's "Florist's Directory," appeared in 1792; and it is still the standard book of instructions for the cultivation of the hyacinth, tulip, ranunculus, anemone, auricula, carnation, pink, and polyanthus, the favourites of the *florist*, strictly so called. The "Exotic Gardener," by J. Cushing, foreman to Messrs Lee and Kennedy of Hammersmith, is the latest and best treatise on the management of the hot-house, green-house, and conservatory, and on the soils suitable to tender exotics in general.

19. In the Philosophical Transactions for 1795, the first of Mr Thomas Andrew Knight's horticultural papers made its appearance: it is entitled, Observations on the grafting of trees. In the Transactions for 1799, 1801, and 1803, are contained his ingenious papers on the fecundation of fruits, and on the sap of trees. His excellent little "Treatise on the Culture of the Apple and Pear," was published in 1797. He has presented several interesting communications to the Horticultural Society of London, which are published in the Transactions of that society, to be afterwards noticed.

In the hasty sketch which has now been given of horticultural writers in England, many have been passed over, some of whom would deserve notice, and perhaps commendation, in a more detailed account.

20. Scotland has been more distinguished for producing excellent practical gardeners than good publications on the art of gardening. There does not appear to have existed any Scottish system of gardening, as a separate book, till the beginning of the 18th century, when "The Scots Gardener" was published by John Reid, gardener to Sir George Mackenzie of Rosehaugh. The work is divided into two parts; the first treating of contriving and planting of gardens, orchards, avenues, and groves; the second, of the propagation and improvement of forests and fruit trees, kitchen herbs, roots and fruits; with a gardener's calendar; the whole adapted to the climate of Scotland. The style is very inaccurate; but the matter evinces not only an acquaintance with previous horticultural works, but a practical knowledge of the subject. About thirty years after the publication of Reid's book, there appeared "The Scots Gardener's Director, by James Justice, F. R. S. and one of the principal clerks of Session," (*i. e.* of the Court of Session or supreme civil court of Scotland.) This is characterized, by Professor Martyn, as "an original and truly valuable work, founded upon reflection and experience." Nearly at the same time Dr Gibson published an anonymous octavo volume on fruit-trees, containing many useful remarks, and some curious notices concerning the history of the most esteemed apples and pears of Scottish origin, or which are generally supposed to be of Scottish origin. In 1744, there appeared a small octavo volume, entitled "The Planter's, Florist's, and Gardener's Pocket Dictionary, by James Gordon, nurseryman at Fountainbridge near Edinburgh." It is avowedly a compilation; but the author, being a practical gardener, occasionally gives his own opinions and practice. It has already been seen, that several of the Scottish gardeners who have settled in England have attained distinction as authors. We allude, in particular, to Abercrombie, the voluminous writer lately spoken of, and to Forsyth, the author of the Treatise on Fruit-trees.

21. Among the recent Scottish writers on gardening, one remains to be mentioned, who will long hold a distinguished place,—the late Mr Walter Nicol. He was the son of the gardener, who planned and executed the extensive pleasure-grounds of Raith in Fifeshire; and here he received his horticultural education. He afterwards acted for some time as gardener to the Marquis of Townsend at Reinhamhall in the county of Norfolk; but he left England in order to take charge of the fine gardens and grounds of General Wemyss of Wemyss-Castle in Fife, the improvements there having been conducted under the directions of his father. Here he observed a praiseworthy practice, now too much neglected by head-gardeners,—that of instructing his young men or assistants, not only in botany, but in writing, arithmetic, geometry, and mensuration. He used to remark, that he thus not only improved his scholars, but taught himself, and made his knowledge so familiar, that he could apply it in the daily business of life. In this way he gradually became qualified to communicate his information to the public. In 1797 the first of his works appeared, under the title of "The Scots Forcing Gardener," in one volume octavo. About this time he changed his mode of life, and dedicated his whole attention to the planning and improving of ornamental grounds. In 1803 he published the "Practical Planter," a book which both increased his reputation as a writer, and extended his employment as an improver. In 1809 appeared the "Villa Garden Directory," a little book which soon acquired the high character which it still retains. The "Gardener's Calendar," in one large volume octavo, came out in 1810, and forms at this day one of the best books on horticulture in our language. In the same year he undertook an extensive journey through England, visiting all the principal seats and plantations in that country; and on his return he made some progress in

composing a "Planter's Calendar." But after a few weeks illness he died, on the 5th March 1811. His last work just mentioned, has since been completed and published by his friend Mr Edward Sang, nurseryman at Kirkcaldy in Fife.

22. In 1805, a Horticultural Society was instituted at London, under the patronage of Earls Dartmouth and Powis, Sir Joseph Banks, and other distinguished characters. The first volume of its Transactions appeared, in 4to, in 1812, containing several useful and scientific communications, by Mr T. A. Knight, Mr R. A. Salisbury, and other ingenious horticulturists. In 1809. the Caledonian Horticultural Society was established at Edinburgh, by the individual exertions of that venerable physician and excellent amateur gardener Dr Andrew Duncan, senior, Professor of the Institutes of Medicine in the University there. The Society has been fostered by several of the Scottish nobility and gentry, particularly the Duke of Buccleuch, the Earl of Wemyss and March, the Earl of Leven, Sir James Hall, Sir George Stewart Mackenzie, Sir George Buchan Hepburn, and others. It publishes Memoirs, in the octavo size, in detached parts or numbers, two parts generally appearing in the course of the year; and some important enough papers have in this way been brought before the public. A desire of improving their knowledge of gardening has thus been excited among gentlemen; and the intelligence and zeal of practical cultivators is thus, in the most unassuming way, made known to the world.

23. Perhaps no fitter place may occur for warning gentlemen of the value of the services of an experienced gardener, and of the propriety of employing only, one who has made himself acquainted with all the parts of his business; as well as for inculcating on gardeners themselves, the necessity of their diligently and practically studying every branch of their profession. A well informed and judicious gardener, instructed by experience, is a treasure which every gentleman should prize. Numerous as are the books on gardening, and excellent as some of them undoubtedly are, there are many parts of the gardener's duty for which no general rules can possibly be laid down: like the physician, he has to deal with the living principle, and his treatment of his trees, especially, must vary, according to a thousand nameless circumstances. Much must depend at all times on his own sagacity and observation; but very much is to be learned by a young gardener, from practising under the eye of an experienced master. A gardener ought to have some knowledge of chemistry, particularly of the doctrines of heat, of the nature of water, and of vegetable physiology. All good practical gardeners, indeed, become chemists to a certain extent, without knowing it.

The profession contains different departments. The cultivator of rare plants, or the botanical gardener, may excel in his own department, and yet be very little acquainted with the proper management of fruit-trees. The fruit-gardener generally possesses a knowledge of the culture of kitchen vegetables: but a great proportion of the common order of workmen, who have acquired a competent knowledge of the last-mentioned branch of horticulture, are extremely ill informed concerning the treatment of fruit-trees. 1. The business of the botanical gardener implies, as already remarked, the cultivation of all sorts of rare plants, either in the open border, in frames, in the green-house, the conservatory, or the stove; the adapting of the soil and artificial climate to the respective kinds of plants; a discriminating eye, and an acquaintance more or less familiar with the characters and names of the genera and species of plants, as described by Willdenow, at least of such as are contained in the Hortus Kewensis, or the Cambridge Catalogue. To these qualifications must be added, general taste in the disposing of plants in borders, and in the forming and keeping of ornamental grounds. 2. The fruit-gardener should have a correct knowledge of the different kinds of fruit-trees, and the principal *varieties* of each kind; he must be familiarly acquainted with the method of training and pruning suited to each sort, and must at the same time possess judgment and experience, to enable him to adapt the degree of pruning or mode of training to the peculiar circumstances of the individual tree. He must understand the formation of fruit-tree borders, the operations of grafting and budding, and the preserving of blossom. The peach-house, the vinery, and the pine-stove, belong to his department, as well as the melon frames, and some other subordinate matters. Much may be learned from authors; from Miller, Forsyth, Hitt, Speechly, and others; but an intimate acquaintance with the proper training, and the proper pruning and disbudding of wall trees, is to be acquired only by observation and practice, as they vary continually, according to the soil, aspect, luxuriant or weakly state of the tree, and even according to the season. 3. The kitchen-gardener's duty is generally thought to be very simple and easy; but he who can perform it neatly, and with success, may be accounted a good general gardener. The rearing of several culinary articles requires particular attention; such as asparagus, celery, sea-cale, mushrooms, and, above all, melons and cucumbers. Great assistance may be derived from books,—from Abercrombie's Practical Gardener, and Nicol's Calendar; but a person who has never witnessed nor practised any of the nicer parts of the kitchen-gardener's duty will be but ill qualified to attempt them.

The public nurseries are useful seminaries to young gardeners. The overseers of these establishments are generally well informed persons, and dexterous workmen, having been selected on account of possessing these qualities. Many very useful parts of the profession may here be acquired; such as the level-digging of ground, and neat finishing off of beds or borders,—apparently simple matters, in which, however, many gardeners are extremely deficient. In some nurseries, extensive collections of hardy and green-house plants are kept, and a knowledge of the culture of these may thus be acquired. Nor is the knowledge of the modes of raising from the seed, and rearing in nursery-beds, of the various forest-trees, an inconsiderable matter: in many places, indeed, the head-gardener is required to maintain a nursery of seedling forest-trees, for the use of his master's estate. In the public nurseries, a knowledge of the processes of grafting and budding may be acquired; but the gardener, who has studied only in this school, will afterwards discover how much he has to learn as to the proper wood to be used for grafts, as well as to the size and quality of the stocks. Under any of the first rate market-gardeners, a young man may learn many parts of his profession with great advantage, particularly the raising of all sorts of pot-herbs and salads, and the forcing of many of them. But here too he will labour under disadvantages; for in few such gardens can he acquire any knowledge of the management of fruit-trees, particularly peaches, apricots, and the finer sorts of pears.

A young gardener, who has spent his time in places where the proper management of fruit-trees was not attended to, or where no opportunity of attending to it existed, may possibly be willing to accept lower wages, in order to compensate for the defect of his education. But the proprietor of the garden will soon find himself a loser by the injudicious economy of employing him: and if it were a general rule, steadily followed by gentlemen, not to employ, as their gardeners, persons who had not duly sought opportunities of gaining an acquaintance with the different branches of their profession, young men of merit would, instead of grasping at the situation of head-gardener immediately upon the expiry of their apprenticeship, be convinced of the necessity of *practically* studying every department of their "multifarious and numerous employment," as Evelyn happily styles it. In Germany, it may be remarked, a gardener has not only to serve a long apprenticeship, but to pass certain examinations, before he can be recommended to a situation as head-gardener. In this country there is no such regulation; and the greater necessity, therefore, for the employer being able to judge of his gardener's qualifications.

24. Scotland has long been distinguished for producing gardeners in greater numbers than any other country of Europe; and several of them have risen to the highest eminence in their profession. At the present day many of the nobility and gentry of England employ Scottish head-gardeners; while the numbers of those of an inferior order, to be found in every county south of the Tweed, is quite surprising. Some of the causes of the very great number, and of the real excellence, of the Scottish gardeners, have been assigned in the 9th chapter of the "General Report of Scotland." One is to be found in the early education secured to the children of the labouring class in that country, by the ancient and most laudable institution of parish schools: another, in the hardy mode of life and sober disposition of the young men, which have very generally gained them the esteem of *English* masters; and a third, in the tendency which struggling with a very variable climate at home, has to call into action all the powers of the mind, and to create a habit of unceasing attention to the duties of the station. It may here be mentioned as a striking and very honourable trait in the character of the Scottish master-gardeners of the last age, (already mentioned, § 21) that it was a common practice among them to spend a part of the evening in instructing their apprentices in different branches of education, particularly arithmetic, mensuration, drawing of plans, and botany. Even at this day, there are still in some places of Scotland to be found the remains of this praiseworthy custom. A turn for reading and study was thus created among young operative gardeners; and to this, their rise in life might in many instances be traced. The taste for reading was perhaps never more prevalent among gardeners than at this day. Nor do they entirely neglect geometry, though it must be admitted that this kind of knowledge is on the decline among them. It is not, indeed, now nearly so necessary as formerly to the professional gardener, grounds being no longer planned into regular mathematical figures, and topiary work being altogether exploded.

25. We have little fear of being accused of partiality when we give a favourable report of the character of Scottish gardeners, the justness of their claim of merit being universally recognized: but, without enlarging farther on the topic, we proceed to give some very general account of the different kinds of gardens now existing in Britain. All of them, we think, may be arranged under one or other of the following divisions. a. Royal gardens, and public botanic gardens. b. The gardens of noblemen and gentlemen of great opulence. c. Villa gardens. d. Cottage gardens. e. The public nurseries, which, especially near London, may without impropriety be ranked as gardens. f. Market gardens. On each of these heads, a few examples and observations seem necessary for illustration, and at the same time they may prove not unentertaining.

*Royal Gardens.*

26. The Royal Gardens at Kew, on the banks of the Thames near London, are perhaps the first in the world for variety of plants. They were originally planned by that distinguished character Frederick Prince of Wales, father of King George III. The extent is about 120 acres. The surface is flat; but owing to the tasteful disposition of trees and shrubs, the grounds exhibit a considerable variety of scenery. They are nearly surrounded by wood, amidst which rises a pagoda, or Chinese temple, to the height of 160 feet: this was designed by Sir William Chambers, who afterwards published a description of the gardens and palace of Kew, in folio. The exotic garden was established about the year 1760, after the Prince's death, chiefly by the influence of the Marquis of Bute, a great encourager of botany and gardening. He placed it under the care of Mr William Aiton, who had long been assistant to the famous Philip Miller at Chelsea. The principal green-house and orangery is 145 feet long, 25 high, and 30 broad. About 1794, a large green-house, 110 feet long, was erected, for the reception of African and Cape plants only. There are twelve other hot-houses of various descriptions. Adding together the lengths of all the hot-houses, the garden contains no fewer than 839 feet in length of glass; and besides this, about one-half of the houses have covered borders in front, for the protection of different kinds of bulbs, and alpine plants, during winter. One of the hot-houses is appropriated to the palm and fern tribe, displaying the gigantic species of warm climates almost in their native luxuriance and beauty. Another is devoted to the plants of New Holland, which have a character of foliage peculiar to themselves, so that the botanical visitor finds himself suddenly carried, as it were, into a new world. A third contains chiefly the plants of China, and of these the collection is very rich, a magnificent assortment having some years ago been procured from Canton, accompanied by a Chinese gardener to take care of them. A catalogue of the plants of the garden, entitled "Hortus Kewensis," was first published in 1768 by Dr Hill. A more scientific work, under the same title, was given to the public in 1789, by Mr Aiton, the superintendant, assisted by Dr Solander; this extended to three volumes octavo. Between 1810 and 1813, an improved and enlarged edition, in five volumes, octavo, was published by Mr William Townsend Aiton, who had succeeded his father: he was assisted in the first three volumes by the late Mr Dryander, and, after the death of that botanist, in the remaining two volumes, by Mr Robert Brown, author of the "Prodromus Floræ Novæ Hollandiæ," and justly considered as one of the very first botanists of the age.

The Royal Gardens at Hampton Court were laid out by London and Wise, already mentioned as nursery-men and gardeners of eminence in the reign of King William. A labyrinth in the wilderness quarter, and some other remains of the old style, are here still to be seen, having in some strange way or other escaped during the revolutions of taste, and the desolating improvements of Kent and Brown. The winding walks of the labyrinth are about half a mile in length, although the entire space occupied by it does not exceed a quarter of an acre. In a grape-house on the south side of the palace, is a Black Hamburgh vine, which has been much spoken of: the stem is more than a foot in circumference; one principal branch, trained back, measures 114 feet in length; and the plant has produced, in one season, 2200 bunches, weighing on an average 1lb. each.

The gardens at Kensington have long been celebrated, They were greatly improved by the late Mr Forsyth, who certainly succeeded in renovating the fruit-trees, and rendering them productive of excellent fruit. Too much was probably ascribed to the composition, now generally known by the name of *Forsyth's plaster*, and it was no doubt injudicious to bring such a matter before the British parliament. The effect of the preeminent degree of patronage bestowed seems unluckily to have been, to excite an undue prejudice against the practices recommended in the Treatise on Fruit-trees.

The gardens at Frogmore near Windsor have been formed chiefly under the direction of Charlotte Queen of George III. and of Princess Elizabeth, one of their daughters. The gardens display much taste, and are kept in excellent order. They are the private property of her Majesty.

*Botanic Gardens.*

27. The Botanic Garden at Chelsea is supported by the Worshipful Company of Apothecaries of London. The ground was granted to them in the end of the 17th century by Sir Hans Sloane, on condition of their presenting to the Royal Society, annually, fifty new plants, till the number should amount to 2000. In the middle of the garden there is a marble statue of Sir Hans, by Rysbrack. On the north side of the garden is a large greenhouse, and close by it a stove, also of considerable dimensions. Over the greenhouse is a botanical library. On the south side of the garden, near the Thames, are two wide spreading cedars of Lebanon, planted so long ago as 1683; at present (1816) the circumference of one of them, three feet from the ground, is somewhat more than thirteen feet, and of the other almost thirteen feet. The laborious and well informed Philip Miller was superintendant of this garden for many years, and here his admirable *Gardener's Dictionary* was composed. Since the death of Miller, the garden has been rather on the decline, the soil being much exhausted, and the hot-houses having fallen into disrepair. Of late, however, the Company has, at much expence, restored every thing to a state of more than former excellence, the improvements having been conducted by Mr William Anderson, an eminent practical gardener and botanist. Botanical instructions are here given during the summer months by a demonstrator appointed by the Company of Apothecaries.

The botanic garden at Oxford is of considerable antiquity; but the collection of plants is not extensive; and in that famed city of theological and classical learning, no great encouragement seems to be given to the votaries of Flora and Pomona.

The botanic garden at Cambridge has long had a higher character in the botanical world. The collection, however, cannot be accounted very extensive. The many editions of the *Hortus Cantabrigiensis*, published by the late Mr James Donn, the curator, tended greatly to spread its fame. Not that it is to be imagined that *all* the plants enumerated in the Cambridge catalogue are to be found, at any one time, in a living state in the garden; if they were ever cultivated there, it is enough. The catalogue was printed in the shape of a pocket volume, and formed a convenient companion to the garden or greenhouse: in fact, it long regulated the nomenclature of plants in this country. Now, however, many give the preference to the *Hortus Kewensis*, as a more accurate performance; and an abridged pocket edition of this has also been published.

The botanic garden at Liverpool was established by subscription, under the auspices of the patriotic Mr Roscoe. The suite of hot-houses is perhaps the finest in Britain, and the whole establishment is highly creditable to that opulent commercial city. The collection of plants is great, and the many opportunities of procuring seeds from ships, constantly arriving from every quarter of the world, are eagerly embraced by an active and intelligent superintendant, Mr William Shepherd. Here Sir James Edward Smith, the celebrated author of the *Flora Britannica*, and President of the Linnean Society, has occasionally delivered a course of lectures on botany.

A public botanic garden has recently been set on foot at Hull; it is on an extensive scale, and can already boast of a very ample collection of plants. For it the public are in a great measure indebted to William Spence, Esq. well known not only as a naturalist, but as a writer on some questions of political economy.

28. At Dublin, there are now two botanic gardens; one belonging to the Dublin Society, and another to Trinity College.

The former was established about the year 1798. It contains twenty-four acres (Irish). The collection of plants is very extensive. The general arrangement of the hardy herbaceous kinds is according to the system of Linnæus; each Linnean class standing separate in a large grass lawn, and an alley leading from one class to another. Aquatics are necessarily placed by themselves; and near the Aquarium, there is a piece of marshy ground for bog plants. Shrubs form another division, and trees a third. The collections in all of these departments are very extensive. In one part of the garden there is an arrangement, on a small scale, according to the method of Jussieu. Plants indigenous to Ireland are brought together, so as to exhibit the Flora of the country at one view; but they occur likewise in their places in the general arrangement. They have in this garden what are termed *cattle gardens*, containing plants which different animals are supposed to eat or to refuse. There is a piece of ground set apart for making experiments on the different gramina, and also on what are called artificial grasses, such as clovers, trefoils, saintfoin, lucern: this department, if properly attended to, is evidently calculated to be very useful. The stoves and greenhouses are extensive, and contain a numerous collection.

The College botanic garden was established only in 1806. It occupies no more than three acres and a half. It is enclosed by a wall twelve feet high, the south-east aspect of which is faced with brick, and on this the more delicate of the hardy climbing shrubs, and others which require shelter, are trained. Here, for instance, Metrosideros lanceolata flowers every year, and here may be seen the finest specimen in the three kingdoms, perhaps, of Ligustrum lucidum, or the wax-tree of China, and which escaped unhurt in this situation, during the severe winter of 1813, when the original plant from which it was taken perished in England. There is in the garden a general arrangement of herbaceous, perennial, and biennial plants; the annual plants and the gramina being each kept separate. Although the space is small, there is not only a Fruticetum, but an Arboretum; and, with equal taste and judgment, the principal part of this last is so contrived, as to serve for a screen to give shelter to the rest of the garden. There is an extensive collection of the hardy medicinal plants, arranged according to Jussieu's method. There is only one stove and one greenhouse; but the exotics cultivated in these are curious and numerous. Upon the whole, this small botanic garden contains a richer and more varied collection than is perhaps to be found any where else in Europe within the same compass. It does honour to the liberality and public spirit of the heads of the College; and they seem to have been peculiarly fortunate in their gardener, (Mr James Townsend Mackay, originally from the Botanic Garden at Edinburgh), who has here proved, that, to a thorough knowledge of practical horticulture, and extensive acquisitions in botany, he adds an acquaintance with the principles of landscape gardening.

29. The Royal Botanic Garden of Edinburgh was planned, in 1767, by Dr John Hope, then professor of botany. The collection of plants, both hardy and tender, formed by Dr Hope, was uncommonly great; and some of the rarer trees and shrubs planted by him now afford admirable full grown specimens: the Constantinople hazel, (*Corylus colurna*,) for example, now appears as a fine and lofty tree. The assafœtida plant was here first cultivated, by the Doctor, in the open air in this country. The quarter where it grew was sheltered by a yew hedge, and saw-dust was generally laid over the root of the plant during winter. There are two hot-houses, a dry stove, and a large greenhouse; all of them at present in a state of decay; but likely soon to be rebuilt in a magnificent style, and on an extensive scale. Dr Hope was a zealous disciple of Linnæus, and on the death of that illustrious botanist, he placed in the garden a square monument, surmounted by an urn, with the simple inscription, "Linnæo posuit Jo. Hope, 1779." It deserves to be recorded, that in the dry stove a dragon's blood tree (*Dracæna draco*) planted by the Doctor, attained the height of thirty feet, exactly double that of the largest specimen of the plant at Kew; but this invaluable plant, which ought to have been the pride and boast of the Scottish capital, absolutely perished, owing to the want of funds for raising the glass-roof of the house! In this garden lectures are delivered by Dr Daniel Rutherford, Professor of Botany in the University of Edinburgh. The herbarium of the late Dr Hope is kept at the garden. The present superintendant is Mr William Macnab, who was bred at Kew Gardens, and who is at once an excellent cultivator of plants and an acute botanist. Under his management the collection of hardy herbaceous plants has been so greatly enlarged, that it is now excelled only by that at Kew Gardens.

*Private Gardens.*

30. Many of the private gardens in this country are, it is believed, superior in some respects to those of any other. They are maintained in a more liberal style; and the products are not only plentiful, but every kind of fruit and culinary vegetable is of the first quality of its kind. It may be affirmed, that in Britain a gentleman may derive from his own garden, with the aid of glass and of fire-heat, a more varied and richer dessert, throughout the year, than is to be met with on the most luxurious table in any other country. To prove this assertion, it will be enough to run over the fruits successively afforded throughout the year, by a well-conducted British garden. Strawberries, planted in pots and forced in a hot-house, produce their fruit about the middle of April, and forced cherries are ready at the same time. These are followed by early melons, about the beginning of May. In June the first forced grapes and peaches are ready for the table, with the luscious pine-apple: may-duke cherries on good exposures now ripen, and different kinds of strawberries in the open ground are abundant. These, with early melons, grapes, peaches, nectarines, and pine-apples, continue plentiful till August, when the currant and gooseberry come in. By the middle of August the early pears are ready, and the later houses of peaches, nectarines, and grapes, are in perfection, with melons; and by September, the open wall crops of peaches, apricots, and nectarines, green-gage plums, and jargonelle pears, with the late preserved gooseberries and currants, and the early jenneting and oslin apples, swell the dessert. In October, late crops of melons and grapes, with peaches, nectarines, and figs, join themselves with the ripening apples and pears; till, towards the end of it, the careful horticulturist gathers and stores the remaining fruits of his labours, that he may possess a supply during the winter season. The autumn pears, such as the beurré and the crassane, are in season till the new year; when the colmart, St Germain, and chaumontel, still prolong the succession of pears: then many varieties of keeping apples present themselves, till the season revolve, when *early* strawberries, cherries, and melons, may again be procured. Several fruits, not generally cultivated, such as oranges and shaddocks, have not here been enumerated; and our nuts, such as filberds and walnuts, are intentionally omitted.

The general extent of the walled garden is from two to five acres. It is to be observed, that a walled garden of three or four acres, at the present day, affords as much space for the production of fruits and kitchen vegetables, as did a garden of perhaps five or six acres at the end of the 17th or beginning of the 18th century, when the garden was invariably connected with the mansion-house; so that the portion next the house was naturally laid out as a parterre, and large spaces were occupied by arbours, fountains, and grass-plats for statues or obelisks. A very few only of our modern fine gardens can here be particularized. In all of them, fruits and vegetables are cultivated with great care, and with remarkable success. In most of those to be now specified, besides these more ordinary productions, there are rich collections of curious and ornamental plants.

31. To begin with England. The gardens at Chiswick House, the seat of the Duke of Devonshire, near Kew Bridge, are very extensive, and remarkable for containing a most magnificent range of hot-houses. At White Knights, near Reading, the Marquis of Blandford has a very complete garden, distinguished more especially for a choice collection of ornamental plants. Spring-Grove, near Blackheath, the seat of the illustrious President of the Royal Society, Sir Joseph Banks, affords a very fair example of a well kept English garden. Here, in the open air, grows a noble specimen of the Chili pine, (*Araucaria imbricata*,) the most admirable, perhaps, of the many plants discovered and brought home by Mr Archibald Menzies: of this Spring Grove specimen the venerable owner is justly proud. Wormly Bury, the seat of Sir Abraham Hume, near Enfield, may also be noticed; it is particularly remarkable for its hot-houses being stored with fine specimens of the rarest tender exotics. Other gardens well deserve notice, such as Lord Tankerville's near Walton; the Duke of Northumberland's at Syon House, Brentford; and Earl Mansfield's at Caen Wood, Hampstead.

32. Scotland can boast of some first-rate gardens. The Duke of Buccleugh's at Dalkeith contains, within and without the walls, 13 acres. Every thing here is in a princely style: the gravel walks of the place are about fifty miles in extent. Though the soil of the garden was originally bad, and the subsoil is still unpropitious, the whole has been brought to a most productive state by the ingenuity and judgment of his Grace's gardener, Mr James Macdonald, as will afterwards be more particularly mentioned. The Earl of Eglinton's garden at Eglinton Castle, Ayrshire; the Duke of Montrose's at Buchanan, in Dun-

bartonshire; the Earl of Mansfield's at Scone, in Perthshire; and Mr Ferguson's of Raith in Fifeshire, may also be named.

33. In Ireland there are many excellent private gardens. In the vicinity of Dublin, the Lord Lieutenant's deserves notice, as well as the Chief Secretary's Lord Castlecoote's, and the Lord Chief-Justice Downe's. The garden of the latter at Merville, two miles south of Dublin, besides producing fruit and kitchen vegetables in perfection, is distinguished for abounding with rare flowers of every description, collected with great taste and assiduity. There is here a separate collection of American natives. At Collon, in the county of Lowth, the Right Hon. John Foster has the richest and most varied plantations of trees and shrubs of every kind, to be seen in Ireland, and probably among the best in Britain. Mr Latouche's garden at Bellevue, in the county of Wicklow, likewise deserves to be mentioned as of the first rank, both for fruit and for a general collection of plants. At Castle Forbes, too, in the county of Longford, the Countess of Granard has a fine collection of flowers. Scottish head-gardeners, it may be remarked, are equally prevalent in Ireland as in England. Three out of the four principal gardens in the vicinity of Dublin, above specified, are under the management of Scotsmen.

*Villa Gardens.*

34. These are innumerable; some of them are kept in the highest style of excellence. They are generally about an acre in extent; but many are nearly twice that size. Under this head, are included all the gardens attached to the country houses of those in the middle ranks of life: a few also, belonging to opulent individuals, who devote their leisure to the study of botany and the cultivation of curious plants, must be ranked under this class, though in some respects far excelling the most extensive gardens. Such is the Count de Vande's garden at Bayswater, on the Uxbridge road, remarkable for a very rich collection of plants; and Mr Kent's at Clapton, near Hackney, where aquatics, both hardy and tender, are grown in great perfection. The tender aquatics are kept in a stove during winter; but, in the summer season, the vessels containing them are placed on slight hot-beds under glass frames, where linings of horse-litter can be added at pleasure; it being found, that in this way they flower more freely. Mr Vere, at his villa at Knightsbridge, possesses a very ample collection of rare exotics.

*Cottage Gardens.*

35. Under the title of cottage gardens, must be included all gardens of an inferior sort, such as those common about villages and towns. Cottage-gardens, properly so called, are in some places numerous and well-kept, affording not only an agreeable relaxation to the occupiers, but contributing very much to the comforts of their family. In South Britain, however, they are neither so useful, nor so well managed, as in some parts of Scotland. While in the former the vine may sometimes be seen extending its shoots over the cottage-roof, indicating a mild climate and a fertile soil, the really useful produce of the ground seems much neglected. In Scotland, on the contrary, too little attention is doubtless paid to ornament; but the healthy kale and cabbage plants, and other useful pot-herbs, with well-earthed rows of early potatoes, shew that the inhabitants understand the management of their little spots, and how to draw from them the most effectual assistance to their families.

*Public Nurseries.*

36. The *public nurseries*, especially near London, are of the first order. These, besides being remarkable for general collections of plants, are usually distinguished for excelling in some particular department. Thus at Lee and Kennedy's at Hammersmith, there is not only a most extensive general collection, but more particularly a complete assortment of heaths and other Cape of Good Hope plants. Loddige's at Hackney is distinguished for stove plants; Whitley, Brames and Milne, at Fulham, have a general collection; as have also Malcolm at Kensington, and Jenkins and Gwyther near Paddington. At Thomson's at Mile-End, besides a rich collection of young plants, are many fine old American trees of the rarer kinds, and a very large gingko tree of Japan, (*Salisburia adiantifolia*): at Colville's, on the King's Road, there is a great extent of glass for the growing of snowy plants for the London market; Davy's, in that neighbourhood, is famed for a fine collection of tulips, certainly the first in Britain: Milliken at Walworth excels in auriculas, ranunculuses and anemones; and Chandler, near Vauxhall, in camellias; Gray and Wear at Brompton Park (formerly the nursery grounds of London and Wise) have a great collection of fruit-trees. Mr Joseph Kirke, also at Brompton, has but a small nursery, but it is rich in the newly introduced fruits, particularly those raised by Mr Knight, and those recommended by the Horticultural Society of London. Ronalds at Brentford, and Wilmot and Lewisham at Deptford, may also be mentioned as excelling in the culture and training of young fruit-trees. At what is called the Botanic Garden at Sloane Street, kept by Mr William Salisbury, the partner and successor of Curtis, there is a considerable collection of curious shrubs and plants in general. Several of the nurserymen pay much attention to the production of seeds for the market, either of culinary plants, or of ornamental flowers. Of the principal kinds of the former, such as cabbages, turnips, and peas, they annually raise a small quantity of the different varieties, in their own nursery grounds, and under their eye, taking care however that each variety be as far separated as possible from any similar crop; they examine the plants when in flower, and reject such as are spurious. The whole seed thus procured is kept till next season; it is then sent to some seed-farmer in their employment, perhaps in a remote part of the country, and grown by him. In this way there is yearly procured a large stock for sale, and which in general is not only better saved, but more genuine than what can easily be got in a private garden.

Throughout the kingdom there are public nurseries near all the principal towns. At Edinburgh there are several, which it may confidently be affirmed are kept in a state of greater order and neatness than any in the south; they are particularly distinguished for the excellence of their seedling forest-trees. The number and the flourishing state of the public nurseries may be adduced as a strong proof of the general attention paid to horticultural improvements throughout the country. Towards this they afford great facilities, furnishing, when wanted, every possible variety of plants, at prices comparatively low. In one important article we believe all of them are deficient,—fruit trees. These, indeed, they contain in sufficient numbers; but their quality is often doubtful. This is particularly the case with apples and pears. The grafts for these are often collected from the nursery lines, instead of being taken, as they ought to be, from *bearing branches of fruitful trees.* Sometimes, no doubt, they are selected from fruit-bearing trees in gentlemen's gardens in different parts of the country; but it is frequently impossible for nurserymen to procure grafts of the desired kinds in this way. If any judicious nurseryman, therefore, would form a collection of fruit-trees of his own, to be maintained in a fruit-bearing state, he would thus not only be certain as to the kind which he propagated, but have at his command yearly a moderate quantity of proper grafts from the fruitful boughs of bearing trees. He would thus, no doubt, be limited in the number of his grafts, and might find it necessary to ask a higher price for his plants; but this would most cheerfully be given by judicious purchasers. A nursery orchard of this kind could only, with propriety, be formed on ground the property of the nurseryman, or of which he held a very long lease. Till some such establishment take place, gentlemen who wish to avoid disappointment, must, in general, be content to graft their own fruit-trees.

*Market Gardens.*

37 The *market gardens* near the metropolis are wonderful in extent, and managed in general in the best style. High rents are paid for the ground, so that as many crops as possible must be taken, and those must be of the most productive sorts. At the same time, such is the competition in Covent Garden market, that unless the produce be excellent of its kind, it will be rejected. The accumulated heaps of kitchen vegetables to be seen very early in a summer morning in this place, are quite surprising, and would confound many who have frequently passed through the market in the day time, after vast quantities have been sold, and carried off by retailers, and other quantities have been placed out of sight. If from an inspection of Covent Garden green-stalls, one may judge of the general state of horticulture in Britain, it may be said to approach perfection. It cannot however be denied, that although the kitchen vegetables exhibited for sale in this market excel in size, they are inferior in flavour, and perhaps in wholesomeness, to those raised at a distance from London. Much of the land here occupied as market-gardens has been heavily cropped every year for perhaps a century past, and the soil has been annually replenished with manure from the city. It thus acquires a grossness calculated to give size, certainly at the expense of delicacy of taste. The vegetables of the London markets, however, ought not to be judged of from specimens to be met with in taverns: these are often kept steeping in water for a day, or perhaps two or three days, as if it were intended to extract all flavour, or otherwise sweating in a heaped basket in the cellar, the alliaceous and strong-smelling plants tainting the others. Every one possessed of a garden is well aware of the superiority of potherbs when recently gathered; but those sent to the London market are gathered and packed on one day; they are carried, by the indefatigably industrious gardeners, during night, either in waggons, or by boats on the Thames, so as to reach the market very early the next morning. Even in this way, a complete day and night must elapse before the inhabitant of London can set on his table the freshest vegetables to be procured in the markets. But as the gardeners come to town only three times a-week, on Tuesdays, Thursdays and Saturdays, pot-herbs must very frequently be two or three days kept before they be used. They must therefore unavoidably suffer some deterioration; and the wonder is, to see an enormously overgrown city so amply and regularly supplied, and with articles so excellent in their kind.

38. Fuller, in his "Worthies," fixes the date of the establishment of a market for pot-herbs at London, to be 1590; but Lyson properly remarks, that entries occur in dinner bills of fare, detailed in the account of Queen Elizabeth's progresses, which shew, that "parsley, sorrel, and strong herbs, with peason," were to be *purchased* at least twenty years before that period. *Rathripe*, or early peas, were then accounted a dainty for a queen; and they still continue to be a dainty, selling, when they first come in, at a crown or even half a guinea a pottle (less than a quart.) Other articles, when produced early, give prices high in proportion, asparagus, 6s. or 7s. a hundred; and early potatoes, 3s. 6d. a pound. These and several other culinary plants are therefore extensively *forced* by the London market-gardeners; that is, they are forwarded by the artificial heat either of a hot-bed or of a flued pit. Some idea may be formed of the encouragement given to horticulture by the demand of the metropolis, from considering the extent of ground occupied in the production of kitchen vegetables and fruit within 12 miles of London. Mr Lyson, above named, author of the "Account of the Environs of London," and who, in the course of his minute investigations and inquiries, had a good opportunity of forming an accurate calculation, estimates that at least 5000 acres are employed, within that circuit, in raising kitchen roots and pot-herbs, exclusive altogether of late potatoes, and of vegetables raised for cow-feeders. He states that 800 acres are cropped with fruit, including apples, pears, gooseberries, currants, raspberries, and strawberries. Not fewer than 1700 acres are planted with potatoes for the market; and 1200 with cabbages, turnips, and parsnips, for the feeding of milch cows. The raisers of these articles are properly *farming gardeners:* they manure very highly, and raise garden crops, and then refresh their land by sowing with corn. They abound near Camberwell and Deptford. The production of medicinal herbs employs about 300 acres; and from 400 to 500 are in the hands of nurserymen. In this way, the employment of about 9500 acres of the richest and most highly manured lands in the vicinity of London is accounted for. At Hoxton is a very extensive and well conducted market garden, Mr Grange's; and this may be considered as a fair example of all the others. But the garden ground is chiefly situated near the Thames, both above and below the city, for the conveniency of water carriage in conveying the produce to market, and the not less important advantage of bringing back stable dung, for the construction of hot-beds and the manuring of the ground.

The districts of Brentford and Twickenham are famous for strawberries; and in the last alone, there are about 400 acres in fruit-trees, the produce of which is chiefly sent to London. Fruit arrives from every part of the surrounding country at the same emporium, and yet it is believed the demand is seldom satisfied. It may here be remarked, that the production of fruit, and the supplying of the market with it, should by every possible means be encouraged. It is a just observation of an eminent horticulturist, (Mr Knight,) that the palate which relishes fruit is seldom pleased with strong fermented liquors, and that as feeble causes, continually acting, ultimately produce extensive effects, the supplying the public with fruits at a cheap rate would have a tendency to operate favourably both on the physical and moral health of the people. Isleworth parish is remarkable for producing great quantities of raspberries, which are sent partly to Covent Garden market, but chiefly sold to distillers, or makers of sweets.

In Fulham parish, there are nearly 1000 acres under crops of esculent vegetables, intended either for market or for cow-feeders. In Mortlake parish, there are generally about 80 acres under asparagus; one asparagus grower here, Mr Biggs, has sometimes had forty acres under this crop at one time. Near Deptford also, much asparagus is raised; and one grower here, Mr Edmonds, has, we are informed, at this time, no fewer than eighty acres covered with asparagus beds,—a thing which must appear almost incredible to those who have not witnessed the loads of this article daily heaped on the green-stalls of the metropolis, for the space nearly of three months. About twenty acres in the neighbourhood of Deptford are employed in the raising of onion-*seed*, this article of Deptford produce having acquired reputation all over the country. What are called the *physic gardens* are chiefly near Mitcham, nine or ten miles from Westminster Bridge: in these are raised chamomile, lavender, liquorice, rhubarb, wormwood, and above all peppermint, not only for supplying the essential oil to apothecaries, but for the manufacturing of a favourite cordial.

We have now explained, perhaps, at too great length, the classification of gardens above given: but without going into some little detail, no idea could have been conveyed of the general state of the country in regard to horticulture. We now hasten to make some remarks on the subjects which naturally present themselves as important, when a new garden is projected. Most of them are applicable to several classes of gardens; but when not otherwise stated, a garden of the first character is to be understood as in view.

*Situation, &c. of a Garden.*

39. The consideration of the position of the garden with respect to the mansion-house properly belongs to the subject of LANDSCAPE *Gardening*. It may only here be remarked, that of late it has become fashionable to place the fruit and kitchen garden at perhaps half a mile's distance, or more, from the house. In many cases this has been found inconvenient; and it can seldom happen that the garden walls may not be effectually concealed, by means of shrubs and low growing trees, so as not to be seen, at least from the windows of the public rooms, and the garden yet be situated much nearer to the house. It is scarcely necessary to observe, that an access for carts and wheel-barrows, without touching the principal approach, is indispensable. Some of the circumstances which are considered as constituting the best kind of situation may here be mentioned, and these, it may be remarked, ought never to be altogether sacrificed to effect.

*Shelter* is, in our climate, a primary consideration. This may in part be derived from the natural shape and situation of the ground. Gentle declivities at the bases of the south or south-west sides of hills, or the sloping banks of winding rivers with a similar exposure, are therefore very desirable. If plantations exist in the neighbourhood of the house, or of the site intended for the house, the planner of a garden naturally looks to them for his principal shelter; taking care, however, to keep at a reasonable distance from them, so as to guard against the evil of being shaded. If the plantations be young, and contain beech, elm, oak, and other tall-growing trees, allowance is, of course, made for the future progress of the trees in height. It is a rule, that there should be no tall trees on the south side of a garden, to a very considerable distance; for during winter and early spring, they fling their lengthened shadow into the garden, at a time when every sun-beam is valuable. On the east also they must be sufficiently removed to admit the early morning rays. The advantage of this is conspicuous in the spring months, when hoar-frost often rests on the tender buds and flowers: if this be gradually dissolved, no harm ensues; but if the blossom be all at once exposed to the powerful rays of the advancing sun when he overtops the trees, the sudden transition from cold to heat often proves destructive. On the west, and particularly on the north, trees may approach nearer, perhaps within less than a hundred feet, and be more crowded, as from these directions the most violent and the coldest winds assail us. If forest trees do not previously exist on the territory, screen plantations must be reared as fast as possible. The sycamore (or plane-tree of Scotland,) is of the most rapid growth, making about six feet in a season; next to it may be ranked the larch, which gains about four feet; and then follow the spruce and balm-of-Gilead firs, which grow between three and four feet in the year. Excellent instructions for the formation of screen-plantations, as well as for the regulation of forest trees in general, may be found in "The Planter's Calendar," already mentioned, § 21. Walls and quick hedges are subordinate means of shelter, to be spoken of by and by. The best general *exposure* for a garden, must evidently be towards the south; and a gentle declivity in that direction, equal perhaps to a fall of one foot in thirty, is deemed very desirable; effectual draining being in this case easily accomplished.

*Water* is not to be forgotten. If a streamlet can be brought to flow through the garden, it may be rendered conducive both to convenience and amenity: where this cannot be accomplished, the situation should be such that water may be conveyed by pipes from some neighbouring stream; soft or river water being greatly preferable, for the purposes of the horticulturist, to that of springs or wells. Where running water cannot be commanded, recourse is had to a lake or pond, it being known that water freely exposed to the air and sunshine for some time, becomes comparatively soft, and fit for the nourishment of plants.

In selecting ground for a garden, the plants growing naturally on the surface should be noted, as from these a pretty correct opinion may be formed of the qualities of the *soil*. The *subsoil* should also be examined. If this be radically bad, such as an iron-till mixed with gravel, no draining, trenching, or manuring, will ever prove an effectual remedy; if, on the contrary, the subsoil be tolerably good, the surface may be greatly meliorated by these means. In every garden, two varieties of soil are wanted, a strong and a light one, or, in other words, a clayey loam and a sandy loam, different plants requiring these respective kinds. For the general soil, a loam of middling quality, but partaking rather of the sandy than the clayey, is accounted the best.

*Enclosure Walls.*

40. When the situation is fixed on, the next consideration is the enclosing with walls. Supposing a garden to be about an acre in extent, and the ground sloping gently to the south, the rule is, that the north wall may be 14 feet high; the south wall, 10; and the other walls, about 12. In a larger garden, containing perhaps four acres, the north wall is sometimes raised 18 feet high; the side walls, or those on the east and west, 15; and the south wall, not more than 12. On a dead level the north wall is generally made 16 feet high; the east and west walls 13½; and the south wall 11. It may be observed, that walls higher than 12, or at most 14 feet, are necessary only for pear-trees; peach, nectarines, apricot and plum-trees seldom requiring more than 12 feet. It may also be right to notice, that the terms north and south wall, are here used to denote the north and south sides of a square or parallelogram; but that, in speaking of wall fruit, if it be said that peach or fig trees require a south wall, this must be understood to mean

a wall with a south aspect, or what is in reality the north wall of the garden. There are two motives therefore for raising this wall some feet higher than the others; first, sheltering the garden from the northern blast; and, in the next place, the procuring of ample space for training the finer kinds of fruit-trees on the south side of the wall, or best aspect of the garden. Under the denomination of finer kinds of fruit-trees are to be understood not only peaches, nectarines, apricots and plums, but some of the French pears, such as the chaumontel, colmart, and crassane. Many gardeners are of opinion, that the best aspect for a fruit wall in this country is about one point to the eastward of south; such walls enjoying the benefit of the morning sun, and being turned a little from the violent west and south west winds. South-east is, for the same reasons, accounted by many, a better aspect than south-west. The south-west and west walls are assigned to fruits which do not require so much heat to ripen them as is necessary to those above mentioned; such are cherries, many kinds of pears, and apples. The north walls are appropriated to apples and pears for baking, plums and morella cherries for preserving; and a few may-duke cherry, white currant and gooseberry trees, are trained against these walls, with the view of their affording a late crop.

Bricks, it is generally allowed, are the best material of which to construct the walls. The foundation and basement are often made of common building sandstone, while the superstructure is brick; and sometimes the back part of the wall is of sandstone, and the front only of brick. Sandstone which rises in flags is the best substitute for bricks. Both kinds of materials admit of the branches of the trees being nailed in regularly, and without difficulty. Where the walls are of common rubble building, a trellis of spars is sometimes placed against them, and to this trellis the branches are tied with osier-twigs or rope-yarn. This is regarded as a very good plan; but the expence is considerable, as, to prevent the lodging of insects, the trellis must be smooth and painted. The trees thus enjoy the shelter and reflected heat of the wall, without being injured by its dampness in rainy weather; and as the wall is not injured by the driving and drawing of nails, there are fewer lurking-places for the wood-louse and the snail. The rails of the trellis are made closer or wider, according to the nature of the tree to be trained against it. In a few instances in Scotland, walls have been built of different kinds of *whinstone*, chiefly greenstone and basalt. These minerals, on account of their almost black colour, are calculated to absorb and retain more heat than stones of a light hue: but it is to be considered, that it is not the heat retained by the wall which benefits the tree, so much as the heat reflected from the wall. The proposal of painting walls black is, on the same principle, not admissible. It may here be of some importance to remark, particularly as applicable to Scotland, that in building brick walls, *bricklayers* only should be employed; stone-masons working as awkwardly and clumsily with bricks, as bricklayers would do with masses of whinstone.

As the walls of a garden form one of the principal sources of expence, it is proper, before proceeding to build, to ascertain correctly the average level of the borders, if the ground be unequal, so as to suit the depth of the foundation to it. If the inequalities be considerable, both walls and borders are made to sink and rise, so as to humour them. Declivities in a garden are not unpleasing; and when they happen to slope to the south or east, they afford the earliest crop of different legumes, such as peas or beans. Some improvers have constructed a series of low flat arches as the basement of the wall, these arches having their tops on a level with the surface of the borders; the piers left are from two to four feet broad, according as the foundation is firm or otherwise. The advantage consists not merely in saving much building, but in permitting the roots of the wall-trees, which are planted opposite to the arches, to extend themselves in every direction, and draw nourishment from the soil on both sides of the wall. In some places projecting stone buttresses are set at intervals in the walls, in order to strengthen them, and to break the force of the winds when sweeping along. But to this latter purpose they contribute little: temporary screens of reed, projecting at right angles from the wall, and removed after the blossoming season, when the chief danger is over, are thought better: and if any sort of strengthening columns or piers be necessary, they can be built so as to project only on the outside of the wall. In this country, walls are generally made of the thickness only of three bricks laid side by side, or somewhat more than a foot; and to such walls, in exposed situations, buttresses may be very proper. When the walls are intended to be high, indeed, they are commonly made sixteen inches thick for a few feet above the basement, and then gradually reduced to twelve or thirteen. The basement, whether of brick or stone, is always about six inches thicker than the lower part of the wall.

Walls have sometimes been built with curves; and in perfectly calm weather, the trees in these curves must receive more heat than on a straight wall; but it is found that in windy weather they suffer much more; and that even when there is only a slight air of wind, a draught is produced around the trees, rendering their situation colder than if they were at a distance from the wall. Curved or semicircular walls are therefore no longer constructed. The inclining of walls to the horizon, in order to their receiving the sun's rays more directly, is excellent in theory, but not adapted to practice. Trellises may be so inclined, or close wooden palings: such indeed have been successfully employed in some gardens, as at Brechin Castle, the seat of Mr Maule of Panmure; where curved walls may also be seen. A stone or brick wall, however, could not be sufficiently inclined without the support of a bank of earth, and this would inevitably keep the wall continually damp and cold. A coping is necessary to preserve the wall, not only by preventing the rain from sinking into it at top, but to throw it off from the sides, where its trickling down would do much damage. The best coping is formed of long pieces of freestone, neatly hewn from four inches thick in the centre to two at the plinth; the edges being made to project beyond the wall about two or three inches, and a groove being run underneath the plinth, to collect and throw off the drops.

What is commonly called the *kitchen-garden* has, in modern times, become almost the only walled enclosure. It is likewise the *fruit-garden*, the walls being chiefly intended for the protecting and training of fruit-trees. These, it is to be understood, are planted on both sides of the wall; the exterior fruit-border being defended generally by a sunk fence and an evergreen hedge, with a wire fence for the exclusion of hares. If, after all, the enclosing walls afford too little room for training, a cross wall is built in the middle of the garden; or where the establishment is large, and where fruit is much in demand, two cross walls are reared. These cross walls are not placed nearer to each other than a hundred feet; if they be two hundred feet separate, it is perhaps better. They can scarcely be said to disfigure the garden; on the contrary, they might be defended, as tending rather to enliven its effect, by presenting new scenes, as the successive central doors are opened. They seldom need to be high; being generally destined for peaches, nectarines, or plums, nine or ten feet are sufficient.

*Hot Walls.*

41. It may be proper in this place to say a few words of flued walls, as by much the best time for their construction is at the original enclosing of the garden. Hot walls are of two kinds; such as are intended to have sloping glass-frames attached to them, thus to a certain extent forcing the fruit; and such as are not calculated for having this appendage, but merely to have screens over the blossoms in the spring. Both are generally built about ten or twelve feet high.

In the first kind of hot wall, a ground plate or low parapet, a foot high, and at the distance of perhaps five feet from the wall, is, in some places, formed for the glass frames to rest upon, these being heavy and strong; the trees are trained on a trellis within a few inches of the wall; and along the border in front of the trees, early crops of peas, kidney-beans, or strawberries, are raised. In other places, the frames are of very slight construction, and easily manageable: they are about two feet shorter than the height of the wall; and this deficiency is supplied by a bordered parapet, on which rest the rafters for supporting the sashes: the space between the bottom of these and the wall, seldom exceeds three feet. One furnace is reckoned sufficient for 45 or 50 feet of such frame-work. When the new wood of the tree is sufficiently ripened, the whole is taken down and carried under cover. When there is a considerable extent of hot wall, adapted for the reception of glass frames, perhaps 250 or 300 feet, particular trees may be forced or omitted, and an opportunity is thus afforded of restoring trees, by allowing them a year's rest. For these hot walls, fire heat is required only for about four months, from the end of February to the end of May, and again for two or three weeks, when the new wood is ripening.

Flued walls, with an apparatus for temporary coverings of canvas, oiled paper, or woollen nets, are necessary for the perfect production of the finer sorts of peaches and nectarines in all parts of Britain north of Yorkshire. Without the aid of artificial heat, the young wood of these trees is seldom sufficiently ripened, in ordinary seasons, to ensure a supply of good flower-buds for the following year; and unless the buds be strong and plump, the chance of a crop the ensuing season is proportionally lessened; and frequently, after a sufficient quantity of fruit has been brought to full size, unless heat be supp ied artificially, in autumn, maturation is not effected. In the northern parts of the island, therefore, it is always proper to construct a portion of the garden walls with flues: the additional expense of forming the flues, particularly where the inside facing only is of brick, is but trifling; and little consideration should be attached to the expence of the small quantity of fuel that may be necessary for promoting the *setting* of the fruit, and for ripening off the young wood in autumn, the time when it is chiefly wanted.

The flues are commonly eighteen or twenty inches deep, and nine inches wide, inside measure, and they make as many turns as the height of the wall will permit. Formerly they made only three turns; but it has been found, that the oftener the flues are returned, provided they draw well, the less heat escapes by the chimney, and consequently the more is evolved from the surface of the wall. The sole of the flue to the length of the first turn, is generally a foot above the level of the border. The front wall of the flue is 4½ inches thick, or a brick on bed, without any inside plastering. In some places a wooden trellis covers the wall; but in general, the trellis does not extend higher than the first range of the flue, the heat above this not injuring the trees: where neatness is much studied, the trellis rods are sunk into a small recess purposely left in the wall, thus preventing the appearance of bulging, which is otherwise unavoidable.

*Soils.*

42. The improvement of the soil naturally becomes an object of great importance at the first formation of a garden; and its subsequent management, or "keeping in heart," as gardeners term it, is a matter of equal interest.

The various soils distinguished by gardeners and horticulturists consist of the simple earths (as they used to be called) of the chemists, particularly argil, silex and lime, mixed in different proportions. It is well known, that some of the principal offices of the soil are merely mechanical; such are, the giving proper support to the vegetable by means of its roots, and the supplying these with water in a slow and convenient manner, the superfluous moisture draining off. A mixture of clay and sand is called *loam*; and according as the one or other of these earths predominates, the soil is denominated a clayey or a sandy loam. In the same way, in some counties of England chalky loams are common; and in other districts, gravelly loams are not unfrequent. When oxide of iron prevails, and renders the clay hard and of a dark brown or red colour, the soil is called ferruginous loam, or more commonly *till*. Boggy or heathy soil consists of ligneous particles, or the decayed roots, stems, and leaves of various carices, heaths and sphagna, and the coaly matter derived from these, generally with a slight mixture of argillaceous earth and sand. While the nomenclature of soils remains so imperfect and unsettled as it now is, there seems no propriety in enlarging further on the different varieties. Some judicious remarks on these, and on the principles on which they should be distinguished and named, may be found in the Agricultural Report of Ross and Cromarty, drawn up by Sir George Mackenzie, Bart.

Carbonaceous matter, and certain salts, in small proportion, are likewise ingredients in a good soil, plants deriving not only support from the soil, and nourishment from the water, and from the decomposition of the water, supplied by the soil to their roots, but also other peculiar sorts of food from the carbon and salts alluded to.

43. Any substance added to a soil, either to supply a deficiency, or to rectify what is amiss, is called a *manure*. The use of manures is, of course, very various. They may be destined to render soil less retentive of moisture, or to make it more retentive; or they may be calculated to communicate carbonaceous matters or salts. With the former view, clay or argillaceous marl form a suitable manure for a sandy soil, and sand or lime for one that is clayey; while dungs and composts of every kind yield the other requisite materials to the soil. For opening clayey soils in gardens, marls are excellent, particularly gravelly marl. Where marls cannot be had, shelly sand, coal-ashes, or wood-ashes mixed with chips of wood, may be resorted to. For binding sandy soils, argillaceous marls or calcareous loams are proper; and the scourings of ditches are often, for this purpose, valuable.

The improvement of cold or sour clay is sometimes effected by scorifying it, or *burning* it, as it is commonly termed. The sward, with two or three inches of the clay adhering to it, is collected in heaps, and brought into a state of red heat, by means of furze, peat, or coals, taking care to add clay on the exterior, so as to confine the fire. Acids and vegetable matters of noxious tendency seem thus to be driven off, and a soil fit for garden culture produced. This is an old practice, which has been lately revived. In Hitt's Treatise on Fruit-trees, published in 1758, there is a chapter "Of the burning of clay for the improvement of land."

44. The soil of a garden should never be less than two feet and a half deep; the best gardeners prefer having it fully three feet. The natural soil, therefore, however good, is seldom of sufficient depth. If it be not two feet, a quantity of earth from the fields is carried in. The cleanings of roads and grass-turf of any kind form valuable additions to garden soil. In the course of trenching, a portion of the subsoil is brought to the surface, and gradually meliorated; but to bring up much of it at once, is very injurious. Soil of the usual depth may be trenched two spit (spadeful) deep; and if this be done every third year, it is evident that the surface which has produced three crops will rest for the next three years; thus giving a much better chance of constantly producing healthy and luxuriant crops, and with one half the manure that would otherwise be requisite. Nicol insists for the deeper soil, and recommends that, after taking three crops, the ground should be trenched *three* spit, by which the bottom and top are reversed; three crops are again to be taken, and the ground trenched *two* spit, by which the soil which formed the top goes to the middle, and that which lay in the middle goes to the surface. After other three crops, the trenching is to be again three spit deep. By thus alternately trenching two spit and three, after intervals of three years, the surface soil is regularly changed, resting six years and producing three; and an approach is thus made to the desirable object of having always a *new* soil.

It is agreed on all hands, that nothing contributes more to the preserving of the soil of a garden in good condition, than exposing it as often as possible to the action of the sun and air. It is a rule, therefore, that garden ground, when not in crop, should regularly be dug *rough*, or if possible *ridged up*, and left in that state to the influence of the atmosphere. If it be allowed both a winter and a summer fallow, the oftener a new surface is exposed the better; after it has lain ridged up during winter, therefore, repeated diggings are given in the spring and summer months. Whether some noxious matter be exhaled, or some fertilizing substance be imbibed, or what may be the precise nature of the operation that goes on, we do not here inquire. The fact is certain, that *aëration*, as it is sometimes called, is of the greatest advantage to garden soils.

45. It has been already remarked, that it is desirable to have soils of different quality in the garden. One of the most generally desired is what is called *mould*, by which is meant a soil in which vegetable earth predominates. Such as is of a bright chesnut colour is preferred: it is usually styled by gardeners, hazelly mould, or hazelly loam, from being of the colour of the hazel nut. The characters of the best mould, according to Miller, is, that "it cuts like butter, does not stick obstinately, but is short, tolerably light, breaking into small clods, is sweet, well tempered, without crusting or chapping in dry weather, or turning to mortar in wet." It should be so open, as not to stick to the spade or the fingers after a shower of rain. Dark grey and russet-coloured moulds are likewise considered good; ash-coloured are commonly bad; yellowish red still worse. Good moulds, after being broke up by the spade, or after rain, if the surface have been recently dug or hoed, emit rather a pleasant smell. What are called brick moulds, or loams, are much esteemed, both by the gardener and the florist, as auxiliaries to mix with other soils.

For some purposes a sandy soil is wanted. In this case, either the *surface* sand, from a sandy pasture, is alone used, as it contains a considerable portion of vegetable matter, or, if pure sea or river sand be employed, light rich mould, nearly in the proportion of one-half, is mixed along with it. For a very great number of plants, particularly in the flower garden, an excellent soil is to be found in the turf of old pastures, and the earth which adheres to the turf to the depth of six or eight inches, mixed with a portion of cow and horse dung in a rotten state, laid together in a heap for at least a year, and frequently turned over. This is a *compost*, and naturally leads us to speak more particularly on the subject of manures.

### *Manures.*

46. Many authors have treated of manures, and given theories of their beneficial action; Fordyce, Hunter, Cullen, Ingenhousz, Senebier, and others. The learned Kirwan wrote a separate essay on this subject. In this work of Mr Kirwan, and in the more recent publication of Sir Humphry Davy, may be found all the information on the matter that is to be obtained by reading. To enter fully on an account of manures, or the theory of their action, would here be out of place. Besides, manures in general have already been treated of in a former part of this work, (See vol. i. art. AGRICULTURE); and the remarks here made, shall be confined to manures considered as particularly applicable to gardens.

47. It is now an established fact in practical gardening, that for the greater number of culinary plants, and for all fruit trees and flowers, composts or compound manures are far preferable to simple dungs, and that till the latter be completely rotted, they should not in any case be suffered to touch the roots of the plants. Even composts should not be too rich. Trees especially are very apt to be injured by the injudicious and excessive use of manure. A very rich compost will stimulate them for a few years to preternatural exertion; but, as remarked by Mr Knight, will in all probability become the source of disease and of early decay. A very good practical gardener, Mr David Weighton, recommends, for cold clayey land, a compost made up in the following proportions: three parts light mould; one part rotten stable dung; one part sharp sand; one part coal ashes; half a part lime; with a small proportion, perhaps an eighth, of pigeon's or sheep's dung. For a light sandy soil, the following are the ingredients and proportions: to two parts of the natural soil, three parts of pond earth, or the scourings of ditches, and three of strong loamy earth; one part of clay, or rather clay-marl, if it can be got; and two parts of stable or cow-house dung.

In the opinion of some gardeners, the best mode of applying compost manures is, to trench deep, and put compost in the bottom, to the thickness perhaps of eight inches; then to lay on the old garden soil, and to cover the whole with compost to the depth of some inches. In this way, the old or worn out soil is placed in the middle, and is exposed to the effluvia which may arise from the lower stratum, and at the same time is incorporated, by digging, with the upper.

48. In the neighbourhood of the coast, sea-weed is often used; and if dug in soon after being collected, its fertilizing powers are considerable; for artichokes, asparagus, sea-cale, and cabbage, indeed, there cannot be a better manure. The careful gardener pays great attention to the preservation of the dung of the stable and cow-house. The essence of these kinds of dung is often in some measure lost, by the drainings being allowed to

escape. These should be collected in cisterns, and poured occasionally over the dunghill or the compost-heap. Indeed, it appears evident, that every large garden, and every well-regulated farm, should be furnished with a close shed as a dung-store; for *dungs*, properly so called, should be as little exposed to the influences of the weather as possible. It is two centuries since this was pointed out by Sir Hugh Platt, who recommends the building of a brick receptacle, and covering it over, so as to prevent the access of rain, and exclude air to a certain degree.

49. Mr Knight has proved, that vegetable matter in its recent and organised state may be employed as a manure, with more advantage than when it has been decomposed. It is evident, that no inconsiderable proportion of its component parts must be dissipated and lost during the progress of the putrefactive fermentation; and it is no less evident, that if this process be made to go on beneath the surface of the soil, the exhaled particles must first be applied to the roots of the plants, before they can escape.

*Fruit-tree Borders.*

50. The proper forming and managing of borders for fruit-trees is a matter of great consequence, especially when peaches and nectarines, vines, and the best sorts of plums and pears, are cultivated. In many old gardens the borders are only five or six feet broad, and are crowded with perennial flowering plants. Such borders are too narrow, and such plants must greatly rob the trees of their nourishment. The border, according to a gardener's common rule, should not be less in breadth than the wall is in height; but the general breadth is only from 8 to 12 feet. If care be taken to make the soil good below the walk, such a border may prove sufficient. If the bottom be not dry, it is made so by means of drains. Many are of opinion, that it should at the same time be rendered impervious to the roots of the trees, by means of lime-rubbish, or clay and gravel rolled hard, or by complete paving: this precaution is particularly necessary where the subsoil is a cold wet till.

The monastic cultivators of fruit-trees in the 13th and 14th centuries were well aware of the importance of this matter, and seem to have been unsparing either of labour or expence. When Mr Ferguson of Pitfour was laying out a new orchard in Aberdeenshire, he found, in clearing out the remains of the garden of the ancient Abbey of Deer, which is included within the precincts of the orchard, a border which had been prepared for fruit-trees in the following laborious and expensive manner: "First, rich soil above three feet deep; secondly, a well-paved causeway; thirdly, a bed of pure sand, a foot deep; fourthly, another causeway; and beneath the whole, a considerable depth of rich earth."

Gardeners always wish the soil of their borders to be more than two feet deep; for pear-trees it should be three feet at least. In many cases, no part of the natural soil is retained; but the entire border is formed, partly of good loam brought from the neighbouring fields, or prepared by rotting some old pasture turf, and partly of such compost moulds as have been already described. When the natural soil is to some extent retained, if it be a strong clay, it is opened by adding sea sand, or coal-ashes that have been kept dry. Sometimes, in place of these, a small proportion of quicklime is used; but this is seldom advisable. If, on the other hand, the natural soil be loose and sandy, the clayey matter to be found in ditches and open drains in ploughed land is resorted to, and laid about six inches thick at the bottom of the border. Many cultivators are particular in adapting the quality of the soil or compost to the nature of the trees to be planted. For apricot and apple trees, the compost usually preferred, consists of three-fourths light earth, and one-fourth strong loam, well mixed and incorporated with some thoroughly rotten cow dung. For peach, plum, and pear trees, a stronger soil is prepared, and the proportions are reversed, the loam constituting three-fourths, and the light soil one-fourth. Cherry-trees, too, like rather a cool bottom; and equal parts of light earth and of loam form for them a suitable soil.

In forming a new garden, it is very advantageous to have the borders prepared a whole season before planting the trees, and that, equally, whether these consist mainly of travelled soil, or of the natural soil enriched by some composts. If the ground be repeatedly turned and ridged up, it is found ultimately to be in a much better condition for receiving the plants.

The soil of the borders is at first made higher by some inches above the walks, than that of the quarters in the interior of the garden: the reason is, that the quarters annually receive a large accession of manure, whereas the fruit-tree borders are afterwards to receive comparatively little that can add to their depth. Some judicious gardeners contend, that such borders are to be manured only with composts, rendered as homogeneous as possible by frequent turning and intermixing. Others do not hesitate to use well-rotted dung: this is dug in with a three-pronged fork, so as to avoid injuring the roots of the trees; and it is generally applied in the month of November, after the winter dressing of the trees.

51. The borders, particularly those next to south walls, are in most places cropped with early peas, or turnips, or some other plant which does not extend its roots deep into the earth; avoiding, therefore, cauliflowers and beans. But many gardeners disapprove of this, especially in the case of peach and nectarine borders; and certainly if a crop be taken, it should be of the lightest kind, such as salad herbs, and perhaps a few scattered patches of ornamental annuals next the walk. In order to avoid using the fruit-tree borders, therefore, it is a custom, in some well ordered gardens, to have low reed hedges or palings run across some of the quarters; to these the earliest peas or beans are closely attached, as they advance in growth, so as to enable them to escape the frosts of March and April more effectually, even than in front of a south wall. It need scarcely be remarked, that fruit-tree borders are kept carefully clear of weeds, and that frequent stirrings with the hoe, or the three-pronged fork, and frequent rakings are practised, the maintaining of the surface in a fresh and porous state being found of singular advantage. When the season proves very dry, they are watered perhaps three times in the week, after sunset.

52. In many situations and circumstances, it is found impossible to form a soil for fruit-trees, with the care, and at the unavoidable expence, which have here been supposed. In these cases it is necessary to adapt the kind of trees to the soil. On soils naturally very light, gravelly, and sandy, peach and nectarine trees do little good: it is better to plant apricots, figs, or vines, which agree with such soils, and, when trained against a wall having a good aspect, will, in the southern parts of the island, afford excellent crops of fruit. On such soils, even espalier and dwarf-standard apple trees are short-lived, subject to blight, and produce only stunted fruit. Next to renewing the soil, the best remedy is to engraft and re-engraft frequently, on the best wood of the trees, giving the preference to grafts of those kinds which experience has

shewn to be most productive and healthy in that particular place. In shallow soils some have been in the practice of making troughs or hollows, and filling them with rich earth, for the reception of the trees: but this is not to be approved of; the roots of the tree will probably be confined to the trough, and it is possible that water may be retained in it. In thin soils, therefore, it is more proper to raise the surface into little hillocks than to dig hollows. If a tree be planted on the general surface, and have earth heaped around it, it will spread its roots in every direction, and to a great distance, in the shallow soil; and some subsoils, such as decomposed trap-rock, or chalk, are themselves calculated to afford much nourishment.

*Division of the Garden, &c.*

53. It is, of course, understood, that the wall-tree borders extend all around the margin of the garden. It naturally follows that a gravel walk should run parallel with them. On the other side of this walk, in very many gardens, there is a row of espalier-trees, (or, to speak more correctly, counter-espalier trees), fixed to trellis-rails. If the enclosure be tolerably extensive, the centre is traversed by a broad walk. If it be of the largest dimensions, and possess a cross wall, or cross walls, the arrangement of the walks falls to be altered accordingly; a main walk proceeding directly to the doors in the centre of the cross walls. The rest of the garden is divided into compartments, and most of these compartments, in some of our best gardens, are laid out in beds four feet wide, with narrow alleys. So many alleys, no doubt, occupy a good deal of room; but the advantages of conveniency and neatness, in enabling the workmen to clean and gather the crop without trampling the ground, seem to compensate the sacrifice of space. For currant, gooseberry, and raspberry bushes, the quarters are of course, reserved undivided; and narrow beds are unnecessary in the case of large perennial plants, such as artichokes or rhubarb. Border-edgings are not in use, excepting for the walks next the walls, and the cross walks in very large gardens; for these, dwarf box is almost universally employed. In the interior quarters, however, parsley may sometimes be observed forming an edging; and thyme, winter savory, or hyssop, are occasionally employed in the same way, and harmonize very well with the culinary crops around.
